COMMISSION.

VICTORIA R.

Victoria, by the Grace of God of the United Kingdom of Great Britain and Ireland, Queen, Defender of the Faith.

To Our right trusty and well-beloved Councillor Hugh Culling Eardley Childers, Our trusty and well-beloved Sir George Elliot, Baronet, Our trusty and well-beloved Henry Hussey Vivian, Esquire, Our trusty and well-beloved Frederick Augustus Abel, Esquire, Fellow of the Royal Society, Our trusty and well-beloved Richard Cory, Esquire, Our trusty and well-beloved George Duncan, Esquire, Member of the Committee of Lloyd's Register, Our trusty and well-beloved John Fenwick, Esquire, one of the Elder Brethren of the ancient Corporation of the Trinity House, Our trusty and well-beloved John Ferguson, Esquire, Our trusty and well-beloved Charles Icely, Esquire, Our trusty and well-beloved John Percy, Esquire, Fellow of the Royal Society, and Our trusty and well-beloved William Young, Esquire, greeting.

Whereas We have deemed it expedient for divers good causes and considerations that a Commission should forthwith issue to make inquiry with regard to the causes of the spontaneous combustion of coal in ships, and the remedies which it may be possible to adopt for preventing and guarding against the same.

Now know ye, that We, reposing great trust and confidence in your ability and discretion, have nominated, constituted, and appointed, and do by these presents nominate, constitute, and appoint you the said Hugh Culling Eardley Childers, Sir George Elliot, Henry Hussey Vivian, Frederick Augustus Abel, Richard Cory, George Duncan, John Fenwick, John Ferguson, Charles Icely, John Percy, and William Young, to be Our Commissioners for the purposes of the said Inquiry.

And for the better enabling you Our said Commissioners to make the said inquiries, We do by these Presents authorize and empower you, or any five or more of you, to call before you, or any five or more of you, such persons as you may judge necessary by whom you may be the better informed of the matters herein submitted for your consideration and every matter connected therewith, and to inquire of and concerning the premises by all other lawful ways and means whatsoever.

And also to call for and examine all such books, documents, papers, or records as you shall judge likely to afford you the fullest information on the subject of this Our Commission, and to inquire of and concerning the premises by all other lawful ways and means whatsoever.

And We do further by these presents authorize and empower you, or any five or more of you, to visit and personally inspect such places in Our United Kingdom as you may deem expedient for the more effectual carrying out of the purposes aforesaid, and to employ such persons as you may think fit to assist you in conducting any inquiry which you may hold.

And Our further will and pleasure is, that you, or any five or more of you, do, with as little delay as possible, report to Us, under your hands and seals, upon the matter referred to you as aforesaid, and that you may have power to certify unto Us from time to time your several proceedings in respect of the matter aforesaid if it may seem expedient for you so to do.

And We do further will and command, and by these presents ordain, that this Our Commission shall continue in full force and virtue, and that you Our said Commissioners, or any five or more of you, shall and may from time to time proceed in the execution thereof, and of every matter and thing therein contained, although the same be not continued from time to time by adjournment.

And for your assistance in the execution of these presents, We do hereby authorize and empower you to appoint a Secretary to this Our Commission to attend you, whose services and assistance We require you to use from time to time as occasion may require.

Given at Our Court at Saint James's, the Second Day of April 1875, in the Thirty-eighth year of Our Reign.

By Her Majesty's Command.

RICH^{D} ASSHETON CROSS.

REPORT.

TO THE QUEEN'S MOST EXCELLENT MAJESTY.

We, Your Majesty's Commissioners, appointed "to make inquiry with regard to the "causes of the spontaneous combustion of coal in ships, and the remedies which it "may be possible to adopt for preventing and guarding against the same," humbly submit to Your Majesty, in accordance with Your Majesty's commands, this our Report on the matters referred to us.

Origin of the Inquiry.

Correspondence between Board of Trade, Lloyd's, and London Salvage Association.

On entering upon this inquiry, a correspondence, commencing in April 1874, was laid before us by the Secretary to the Board of Trade, between that Department, the Committee of Lloyd's, and the London Salvage Association.

From this correspondence, which is appended to our Report, it appears that in April 1874, the Board of Trade decided to hold no more inquiries, under the Merchant Shipping Act, into casualties caused by explosions or fire in coal-laden vessels, for the reason that the finding of their courts, which invariably took the form of an exoneration of the ship's officers and a recommendation in favour of better ventilation, appeared to be entirely disregarded both by shipowning and underwriting interests.

Later in the year the Committee of Lloyd's, having furnished to the Board of Trade a return of the casualties to coal-laden vessels during the preceding 16 months, drew attention to the serious increase in the risk to life that appeared to be involved in the coal trade, and urged renewed investigation into such casualties, in order that the causes of these spontaneous combustions, hitherto so variously accounted for, having been ascertained and made public, such conditions in coal cargoes as were shown to be dangerous might, as far as possible, be provided against.

Unsatisfactory result of statutory inquiries held under the Board of Trade.

The Board of Trade still demurred to a renewal of their inquiries on the ground that no new facts were ever elicited, and that the conclusions, to which the courts had for years invariably arrived, had apparently been productive of no practical results. They submitted that there was no guarantee that the shipping interests would, in the future, pay more regard to the recommendations of the Courts of Inquiry than they had done in the past; and they suggested that some serious steps should be taken by those who own, manage, and insure these ships and cargoes, to profit by the facts already proved, and to secure the safety of their vessels by better ventilation, by the provision of means for extinguishing fire, and by caution in the description and condition of the coal shipped.

To this the Salvage Association replied by pointing out that the Courts of Inquiry hitherto held were not so constituted as to command the confidence of those concerned in the coal trade; that inquiries conducted, perhaps, by a justice of the peace and two assessors, were not calculated to elucidate a subject so difficult in itself, and rendered further obscure by the great conflict of opinions concerning it. They observed that the facts, which the Board of Trade alluded to as proved at these inquiries, were held generally to have been merely discussed, the conclusions arrived at by the court being of far too uncertain a character to be accepted or acted upon with decision. They therefore strongly urged that an inquiry should be held by a Commission consisting of men of high scientific attainments, and especially acquainted with the nature of coal in all its conditions, and of men acquainted practically with coal both at the pit and in the ship's hold. They pointed out that the result might be to fix with a certainty, absolute or qualified, the causes of this dangerous combustion of coal in ships, thereby attaching to the proper persons the responsibility for due precautions.

They expressed their confidence that the recommendations of such a Commission would receive attention and consideration from underwriters, shippers, and shipowners; and in support of this opinion they referred to a letter from Sir John Pirie & Co., strongly advocating an inquiry, so constituted, into the causes of spontaneous ignition, the best means for its prevention, and the most effective method for its extinction.

This proposal was referred by the Board of Trade in January 1875, to the Committee of Lloyd's, who expressed their hearty concurrence; and effect was given by Your

Majesty, to the suggestion,—so strongly urged in this correspondence on Your Majesty's Government,—by the appointment of a Royal Commission.

General Condition of the Export Coal Trade and the Extent and Circumstances of the Casualties from Spontaneous Combustion.

Information collected.

In the first instance it appeared to us desirable to collect information bearing on the general condition of the export coal trade, the methods of shipment employed at the various ports, the descriptions of coal exported, and the fittings employed in coal ships either for the ventilation or preservation of the cargoes. We also endeavoured to obtain statistics showing, as far as possible, the exact extent of the evil we were to deal with, and the circumstances in which it generally occurred.

Return of casualties, 1874 and 1875.

For this purpose we first obtained from the Committee of Lloyd's a list of the coal-laden ships which had been subject to casualties from fire in the year 1874, and by individual application to the owners and masters of these vessels we procured, so far as practicable, particulars in each case of the tonnage, class, size, build, age, and destination of the vessel, and of the name, tonnage, condition as to moisture and ventilation, and method of loading, of the coal carried, together with the circumstances attending the combustion.

A tabulated analysis of this return, which was subsequently continued for the year 1875, will be found in the Appendix.

Evidence, oral and documentary.

2ndly. We addressed a circular letter to the chambers of commerce at the principal coal shipping ports of Great Britain, requesting them to furnish us with lists of such shipowners, coal-shippers, masters, engineers, staithmen, and others, as they considered it would promote our inquiry to consult, either orally or by letter. The chambers of commerce responded with readiness to this request, and enabled us to obtain information by means of series of questions, copies of which are appended, from a large number of the most important interests connected with the coal trade. We examined some of the witnesses recommended to us by the Board of Trade, Chambers of Commerce, and others whose opinions were likely to be valuable, and we have further received evidence from officers, sent to us by the Admiralty, with regard to cases of spontaneous combustion and of explosion that have occurred in the coal bunkers of Your Majesty's ships, and in certain of the Government coal stores. The minutes of evidence are appended.

Lloyd's return of coal shipments for 1874, showing tonnage, destination, and casualties.

3rdly. We requested the Committee of Lloyd's to prepare for us a return which would show the number of coal shipments, and the quantities of coal shipped from British to foreign ports in 1874, dividing the shipments according to their destinations, classifying them according to the tonnage of the cargoes, and assigning to each group of shipments the casualties that had arisen from spontaneous combustion. This valuable return, the material for which was obtained from the "Bill of Entry Offices" at the ports, entailed great labour on those offices, and still greater on the clerical staff of Lloyd's, and we wish to take this opportunity of acknowledging the valuable assistance we have obtained from that Corporation in the statistical branch of our inquiry.

Scientific paper by Dr. Percy and Professor Abel.

4thly. We requested Dr. Percy and Professor Abel, two members of our Commission, possessing the requisite scientific knowledge, to draw up a paper which should describe, simply and clearly, the chemical conditions which tend to originate and develope spontaneous combustion and those which produce explosion. This paper, which we consider of great value in connection with our inquiry, is annexed to the Report.

General conditions of export coal trade.

From the information collected from these various sources it appears that the export of coal from the United Kingdom is steadily on the increase. In 1873, 12 million tons were sent out of the country; in 1874 nearly 13½ million; and, notwithstanding this exceptionally large increase, last year shows a further advance of half a million, or a total export of nearly 14 million tons.

But of these large quantities of coal which annually leave the country more than three-fourths are destined for European ports, and the returns for 1875 show that the increase in the export for that year is wholly in this direction.

Shipment of coal to European, as com-

How far the unusually large number of fires which occurred in 1874 in coal ships bound to distant and tropical ports, may, by alarming shippers and underwriters, have influenced the shipment of coal on long voyages, we cannot say; but it is remarkable that the export to Africa, Australia, the East and West Indies, and North and South America, which increased by 340,000 tons or over 14 per cent. in 1874, as compared with 1873, show a decrease in 1875 as compared with 1874 of upwards of

190,000 tons, or nearly 7 per cent.; while the export to Europe which in 1874 increased at a lower rate than that to more distant ports (namely at not quite 10 per cent.) still shows an increase of $7\frac{1}{2}$ per cent. in 1875, or a total of 11,400,000 tons as compared with 10,600,000 in 1874. Setting against this the decrease to distant ports we find an increase last year on the total export of coal from the country of over half a million tons. Of this increase more than half went to France which is by far our largest customer.

pared with more distant ports.

Comparative export of coal from the chief coal shipping ports of United Kingdom.

The coal thus annually exported from the United Kingdom is shipped chiefly from the Tyne, the Wear, the Mersey, and the Bristol Channel. The Scotch and Yorkshire ports also sending out a considerable amount.

In round numbers, the following was the export from these ports in the years:

——	1873.	1874.	1875.
From the Tyne -	Over 3 million tons	Over 3 million tons	Over $3\frac{1}{2}$ million tons
" Wear -	Under $1\frac{1}{2}$ million "	Under $1\frac{1}{2}$ million "	Nearly $1\frac{1}{2}$ million "
" Bristol Channel -	Over $3\frac{1}{2}$ million "	Nearly 4 million "	About $3\frac{3}{4}$ million "
" Mersey -	Over $\frac{1}{2}$ million "	Nearly $\frac{3}{4}$ million "	Under $\frac{3}{4}$ million "
" Scotch ports -	Over 1 million "	Over $1\frac{1}{2}$ million "	Over 2 million "
" Yorkshire ports -	Over $\frac{1}{2}$ million "	Over $\frac{3}{4}$ million "	Over $\frac{3}{4}$ million "

Turning from the extent and conditions of the coal shipments for foreign export, we come to consider the extent and circumstances of the casualties from fire, occurring among them, which form the subject of our inquiry.

Extent and circumstances of the casualties in 1874.

From the return prepared by Lloyd's to which allusion has already been made (and which is tabulated in the Appendix) it appears that among 31,116 shipments in 1874, amounting to 13,369,012 tons of coal, the casualties were 70. But of these shipments, 26,631, amounting to 10,513,181 tons of coal, were to European* ports, and only suffered from combustion in 10 cases. This leaves 60 casualties among only 4,485 shipments, amounting to 2,855,831 tons of coal to Asia, Africa, and America.

Again this return shows, to a startling extent, that the proportion of casualties traceable to spontaneous combustion increases *pari passu* with the tonnage of the cargoes. This becomes still more apparent when the European trade is deducted. The return then shows that there were, in 1874:—

2,109 shipments, with cargoes under 500 tons, in which 5 casualties occurred,—or under $\frac{1}{4}$ per cent.;
1,501 shipments, with cargoes between 500 and 1,000 tons, in which 17 casualties occurred, or over 1 per cent.;
490 shipments, with cargoes between 1,000 and 1,500 tons, in which 17 casualties occurred, or $3\frac{1}{2}$ per cent.;
308 shipments, with cargoes between 1,500 and 2,000 tons, in which 14 casualties occurred, or over $4\frac{1}{2}$ per cent.; and
77 shipments, with cargoes over 2,000 tons, in which 7 casualties occurred, or 9 per cent.

The casualties in vessels bound to San Francisco were the most remarkable. Deducting vessels under 500 tons (in which no cases of spontaneous combustion were recorded), the return shows 9 casualties out of 54 shipments. These also increase in proportion to the tonnage of the cargoes, till we arrive at the alarming fact that out of the 5 ships with cargoes of over 2,000 tons sent to San Francisco in 1874, 2 suffered.

Thus it becomes evident that spontaneous combustion has occurred principally in vessels carrying over 500 ton cargoes, bound to the West Coast of South America, San Francisco, or to Asiatic ports beyond the Mediterranean and Black Seas. Of such shipments over 4 per cent. suffered in 1874; and though they only amounted to 1,181 out of the 31,116 shipments for the year, yet among them occurred 51 out of the 70 casualties.

In conducting our inquiry into the causes of spontaneous ignitions in coal cargoes, the chief points which we have found ourselves called upon to consider have been:—

Chief heads of inquiry.

1. Descriptions of coal dangerous for shipment on long voyages;
2. The breakage to which coal is subjected by the various methods of loading employed at the several ports;
3. The effect of moisture;
4. The through ventilation of coal cargoes;

---

* This includes all ports in the Mediterranean and Black Sea.

5. The providing of means for testing the temperature of coal during the voyage; and
6. The question of explosions in coal cargoes, which, though not specifically referred to us, we have ventured to consider within the terms of our inquiry.

Evidence as to dangerous descriptions of coal.

1. *Descriptions of Coal dangerous for shipment.*—This is a very difficult, and delicate, and at the same time a very important, branch of our inquiry. There can be no doubt that certain kinds of coal are of such a quality as to be entirely unsafe for shipment at all, while other kinds should only be shipped for short voyages and under circumstances of great precaution. We desire, as far as possible, to contribute, with regard to these coals, any information which may be valuable in averting danger from life and property, and we would therefore direct attention to the evidence, as to the character of certain coals, given by Mr. Cooper Rundell, Mr. Derry, Mr. Harwood, Mr. Beynon, Mr. Bladon, Capt. Steinson, Mr. Roberts, Mr. Scott, Capt. Cawkitt, and especially by Mr. Glasbrook. All coals mentioned in evidence before us will be found in their proper places in the Index.

Difficulties in obtaining complete information as to character of coal.

It would, however, be of course impossible for us to cite with completeness or accuracy the various coals to be avoided, or their relative susceptibilities to spontaneous heating. The difficulties are two-fold, first, because coals of very different character in this respect are produced from the same colliery; and secondly, because the conditions of shipment may be totally dissimilar. Nor can chemical analysis be relied upon, in every case, to furnish conclusive evidence as to the tendency to ignition. On this subject a letter from Mr. Ferguson, Professor of Chemistry at Glasgow University, will be found in the Appendix.

We are, however, inclined to think that the character in this respect of each class of coal is pretty generally known in the locality where it is worked (see Mr. Bladon's evidence, Q. 1,557, 1,558, and 1,560); and we consider that what is most needed, to avoid the shipment of dangerous coal, is thorough inquiry on the part of coal shippers, into the character of the coal they propose to ship, and subsequently a careful scrutiny of the coal before shipment in order to ensure that the coal contracted for has been actually supplied.

On this point the evidence of Mr. Roberts, Inspector for the Peninsular and Oriental Company at Cardiff, is worthy of attention, and we would refer especially to the answers given by him in evidence to Questions 2,000–2,005.

It appears to us, therefore, most desirable that facilities should be provided for tracing more certainly and easily where the coal, shipped in any particular vessel, comes from. Such means of information, in the case of cargoes which had heated, would enable coal shippers to learn from the accumulation of experience the character of the coals with which they had to deal.

As it is at present, a cargo of coal is constantly taken without even a name being given to it. If heating occurs in such a cargo, the dearly bought experience may prove valueless, there being no means of tracing the coal with which the vessel was loaded.

Provision recommended for securing records of the descriptions of coal exported.

It is of course impossible to insist by law that shippers should inquire into the character of the cargoes they carry, but we consider that the means of doing so, where a cargo has proved dangerous to human life, should be secured. We would suggest, therefore, that, on the "specification (in lieu of shipping bill or Customs bill of loading)" which every exporter has to deliver to the officers of Customs within six days from the time of the final clearance of the ship, as provided by the 23 Vict., cap. 22, he should be required to state the denomination of the coal carried and where it comes from, as well as its quantity and value. The form, as at present drawn up (of which specimen is appended), requires him to state the "quantity and *description* of goods," "but the goods need only be described in accordance with the denomination in the "official list of British and Irish produce and manufacture exported," and in the case of these cargoes the denomination at present given is simply "coal." These specifications are noted at the Custom House in London, and kept with the ship's papers. Were the exporter required to name the coal, or, in a mixed cargo, the several descriptions of coal, loaded in the vessel, and the same penalty extended to a false statement in this respect as now attaches to a false statement of quantity, facilities would be given for tracing to its source, and inquiring into the character of, any cargo of coal in which spontaneous combustion might occur. We would observe that the information we propose to make compulsory is already voluntarily given in the specifications by several coal shippers, especially at the Welsh ports.

Suggestion that Inspectors of

Having made this practice general, we would recommend that whenever a vessel loaded with coal from a British port is reported to have suffered from spontaneous combustion, reference should at once be made to the Customs authorities for the description of the coal given by the exporter, and that it should then be the duty of the Inspector of Mines for the district from which the coal was stated to have come to inquire into the case.

Mines should hold inquiries into all cases of combustion occurring in coal from their respective districts.

This inquiry would not be of the character of a marine inquiry, nor need it interfere with any investigation which the Board of Trade might think it desirable to make. The Inspector would be directed to ascertain as far as practicable the particular seam or seams from which the coal was wrought, the natural character of the coal, its condition at the time of the casualty, the manner and condition in which it was shipped, and other circumstances.

Legislation.

Some legislative provision may be requisite to enable the Departments of Government concerned to carry out these recommendations, but with this exception we advocate no legislation on the subject of our inquiry.

Shipment of small or inferior coal, or of coal insufficiently cleaned.

In connection with the subject of dangerous coal, we desire to draw attention to certain evidence given before us bearing on the shipment of small or inferior coal, and of coal insufficiently cleaned.

Mr. Cooper Rundell, accountant to the Liverpool Underwriters' Association, who had collected for his employers a variety of statistics relating to spontaneous combustion in coal ships, was of opinion that want of care in the selection of coal had a good deal to do with the increase of casualties in 1873 and 1874 (Q. 134). He considered that "the coals shipped in 1874 were most probably not so free from pyrites and small " coal as in the case of the coals shipped in the preceding years" (Q. 135,) and that "the coal agents found a market for the inferior coal they were able to sell and get rid of" (Q. 136). He also pointed out that in consequence of the Mines Regulation Act, which came into force in 1873 and restricted the labour of children, a great many of the boys, who were formerly employed in cleaning and selecting the coal, were no longer available (Q. 137). He adds, "There has been a great demand " for coal, and a ready sale has been found for inferior and unclean sorts, which " would not formerly have been marketable. I have been told this, that formerly " men were fined for sending up bad coal, but that they are not fined for doing so " now. The pitmen, it is stated, would have been fined for sending up so much " bad stuff, and the stony and metallic part of the coal which did come up would be " carefully separated at the pit's mouth. Now the coal agent, in order to meet the " demand, appears to accept anything passed to him." (Q. 137 and 139.)

On the effect of the Mines Regulation Act, Captain Steinson was subsequently examined as follows: *Q.* "You mentioned that the boys who formerly picked out " the pieces of brassy coal no longer do so?—*A.* Yes." *Q.* "At what date was " the practice of employing boys to pick out the brassy pieces of coal discontinued?— " *A.* It has gradually been discontinued since the Mines Regulation Act came into " force." *Q.* "When did the Mines Regulation Act come into force?—"Within the " last two or three years." *Q.* "Those accidents have been more rife since the " cleaning of the coal has been neglected?—*A.* The men have been getting more " careless in every way since then; since they get the big wages they have been getting " more careless." *Q.* Are you of opinion that the coal has been much more carelessly " cleaned since 1872 than previously?—*A.* I will not say much more carelessly; it is " not so carefully cleaned." *Q.* "Have the places of these boys been filled by anyone " else?—*A.* There is a screener at each side of the screen; he is supposed to pick out " the brasses." *Q.* "Did the boys supplement those men?—*A.* The boys supplemented those men." *Q.* "Therefore there was a double check, now there is only a " single one?—*A.* Only a single one." (*Q.* 1736–1743.)

On the subject of the shipment of small coal, Mr. John Bladon, a coal shipper at Newport, said, "I think that the shipment of small coal at Newport in large quantities " is rather a new trade. I think that formerly the small coal shipped at Newport was " generally considered smith's coal, and it was generally sent to the various ports " round the coast, but the shipment of small coal for foreign districts is somewhat of " a new trade." (Q. 1559.) He further said, "There is no doubt that many fresh coals have come into the market within the last few years." (Q. 1560.)

Systems of loading in relation to breakage of coal.

2. *Breakage of Coal.*—This seems generally to be recognised in the trade as an evil to be guarded against; and in advocating the various systems of loading employed at the several ports, their relative merit in avoiding breakage has been always accepted by witnesses as the gauge of their efficiency. It is also important to observe that the experience, in this respect, of shipowners, masters, and shipping agents is strongly

confirmed by the conclusions laid down in the paper drawn up by the scientific members of the Commission to which we desire to draw particular attention.

Visits of Commission to coal shipping ports.

So important did this question of the breakage of coal in loading seem to us, that we thought it desirable to visit the chief coal shipping ports, and inspect for ourselves the working of the various systems.

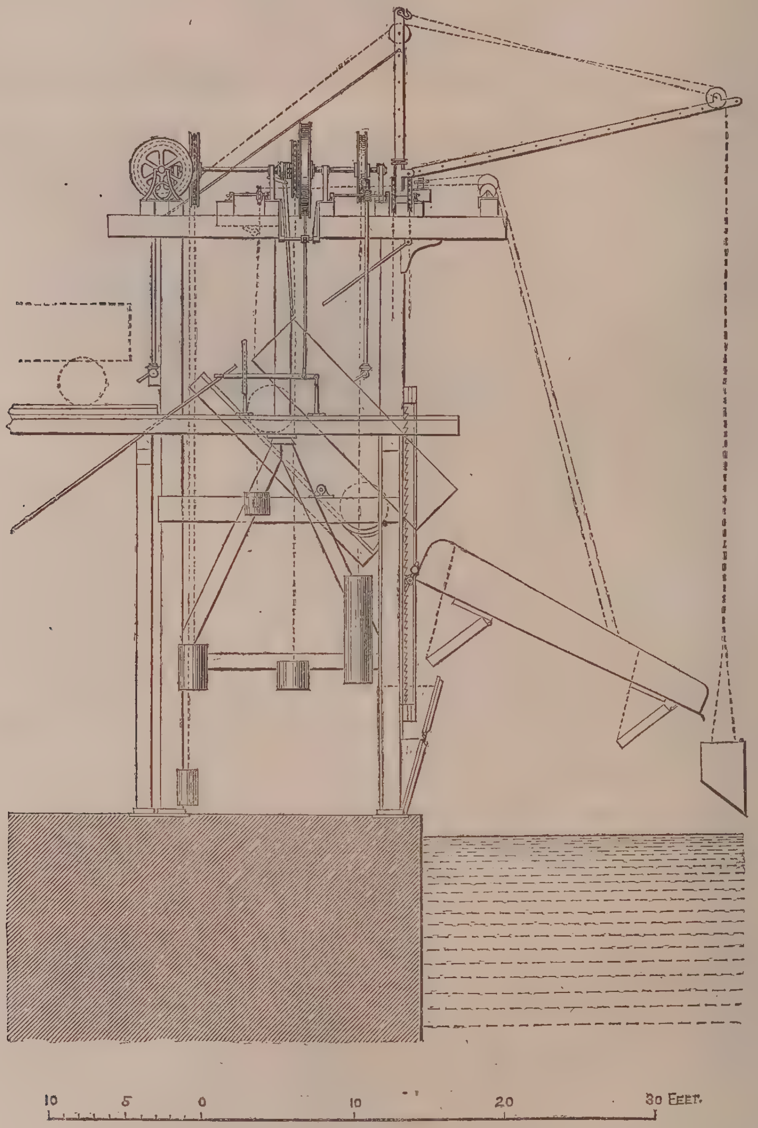
System of loading in South Wales.

Taking first the ports in South Wales, we found at Cardiff that, at the west and east docks, the coal is loaded from a high level by balance tips (also called drops), but that at the new basin the low level system, with hydraulic tips, has been adopted.

Balance tips or drops.

In the balance tips, of which the following are sketches,* the waggon runs from a high level of rails, 22 to 28 feet above the dock coping, on to a platform or cradle. This platform, in the tips of earlier construction, as shown in Fig. 1, is supported by balance weights sufficient to raise it when carrying an empty waggon but unequal to the weight of a loaded one. These weights are connected to the platform by chains passing over pulleys at the top of the framing, upon which are breaks for controlling the motion of the platform. When a full waggon has been run on to the platform a suspended chain is hooked on to its tail, and the platform is lowered by means of the breaks until the waggon is tipped sufficiently. The coal is then discharged through an end door into an inclined shoot which reaches the ship's hatchway. The break is then released, and the platform, with the empty waggon, rises again to the level of the line of rails, and the waggon is run off into a siding, leaving the platform ready for a fresh load. The shoot down which the coal passes to the ship can also be adjusted to any height and at any angle, and has screens at

No. 1.



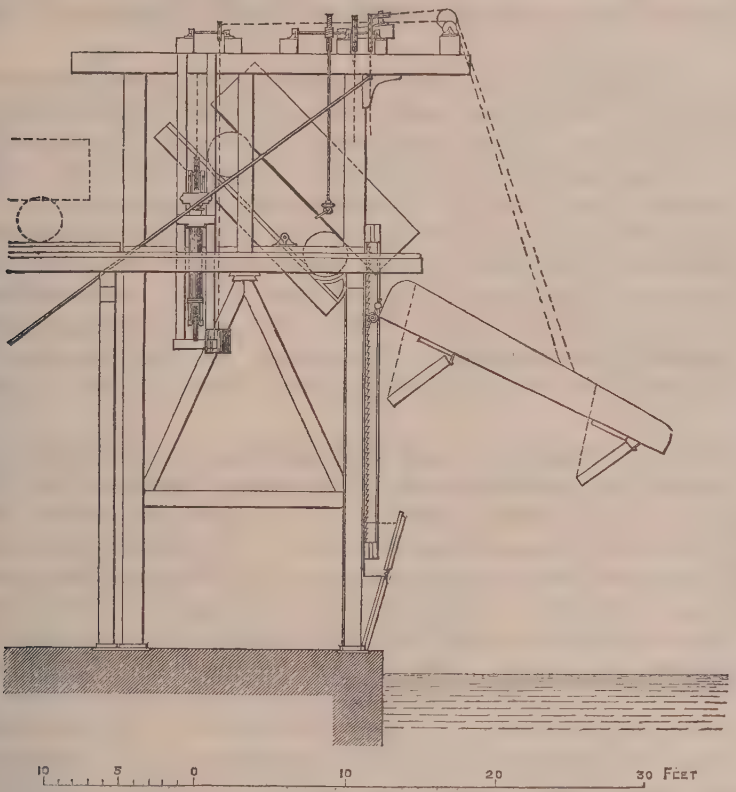
---

* For the particulars and sketches of these systems of loading in use at the South Welsh ports, we are greatly indebted to a paper by Mr. John McConnochie, of Cardiff, engineer to the Bute Harbour Trust.

the bottom for separating the small coal, but these are not always left open. The shoot tapers towards the end, and is generally furnished with a door, so as to check the too rapid descent of the coal.

In the tips more recently constructed this system of tipping, by securing the tail end of the platform with a chain and lowering the other end to the shoot, has been superseded by the introduction of a hydraulic lift, which raises the tail end of the platform until the waggon is tipped to the desired angle of incline, as in Fig. 2.

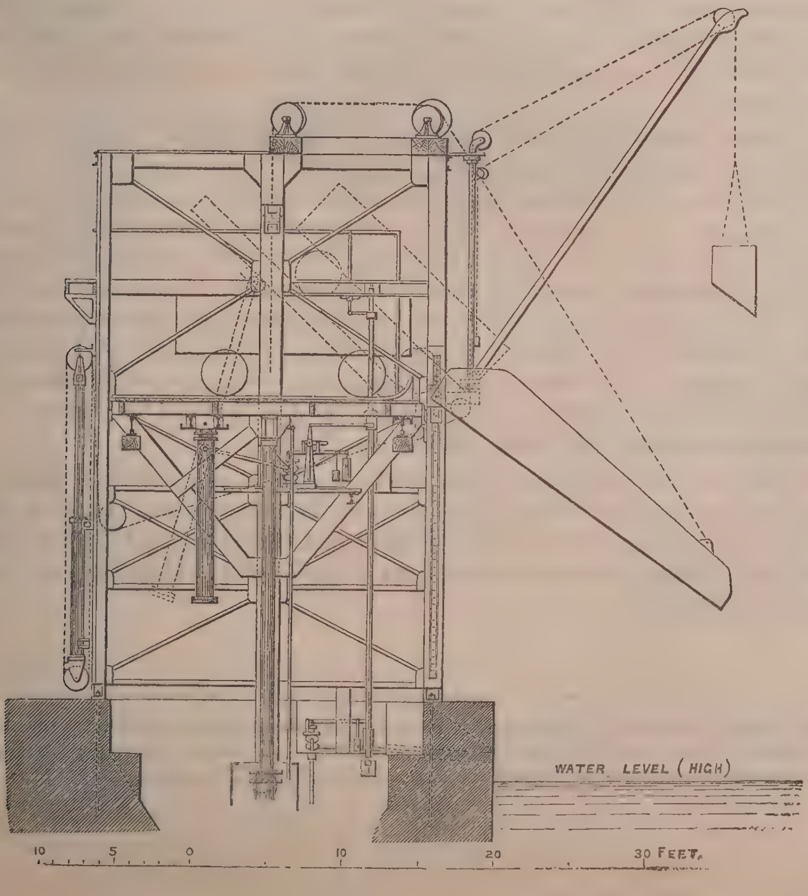
No. 2.



At the new basin, served by the Great Western Railway, which comes into Cardiff on the low level, hydraulic tips have been fitted, of which the following is a sketch :—

Hydraulic tips.

No. 3.



By this method the waggon of coal runs on to a platform level with the quay, and is raised by a hydraulic lift to the height required to tip the coal down the shoot into the hold of the vessel, the waggon being tipped by hydraulic pressure as in the case of the high level balance tips. At low water it is unnecessary to raise the platform, and the cradle, with the rails upon which the waggon rests, is simply tipped, the tail end being raised by hydraulic pressure.

There is little to choose between the hydraulic and balance tips either in facility or rapidity of loading, each tip being capable of shipping about 560 tons of coal a day of 10 hours, and of course, as regards breakage of coal, the effect is the same in both cases.

Antibreakage boxes.

In any system of loading by tips this breakage necessarily occurs to the greatest extent in shipping the first waggon loads, when the coal has to fall from the mouth of the shoot to the bottom of the ship's hold. To meet this serious evil a machine called the anti-breakage box is much used at the south Welsh ports. (For illustration, see preceding sketches, Nos. 1 and 3.) It consists of a hopper-shaped iron box with a hinged flap for discharging at the bottom, and it is suspended from a crane close under the mouth of the shoot. The coal is then lowered by it from the shoot, a ton at a time, to the bottom of the ship's hold, until a cone of coal is formed under the hatchway, the top of which is level with the deck. The box is then removed and the coal allowed to run directly from the shoot. The use of the box, however, seriously delays the loading of the coal in its earlier stages, and unless insisted upon is liable to be neglected.

Box system of loading.

The same systems of loading in use at Cardiff are also prevalent at Newport and Swansea. At Cardiff and at Swansea the box system, introduced by Mr. Brunel, also exists, though to a very limited extent. At Cardiff we believe that the Powell Duffryn Co. are the only shippers who still use it. By this system the coal is loaded, at the collieries, into iron boxes, each containing 2½ tons, and the boxes are conveyed, two on a waggon, to hydraulic hoists fitted on the quay. Each box is constructed with double doors at the bottom, and has three chains, one attached to the box itself and the two others to the doors. The waggon having been run under the hoist each box is lifted off it, and lowered through the ship's hatchway until the bottom of the box is close to the ship's bottom, or upon the surface of the coal already shipped. The doors are then opened by means of the chains and the contents let out. This system has fallen into disuse owing principally to the change on the railway from broad to narrow gauge. It is also less expeditious than the tips, and is generally considered a more expensive method of loading, but it clearly breaks the coal to a far less extent.

Systems of loading at Liverpool.

On the Mersey coal ships are generally loaded by the appliances of the Mersey Docks and Harbour Board. At Liverpool, at the high level railway, the coal is mostly put on board either by cranes, or by hand tips. The following are sketches* of these two methods (page 9).

The crane.

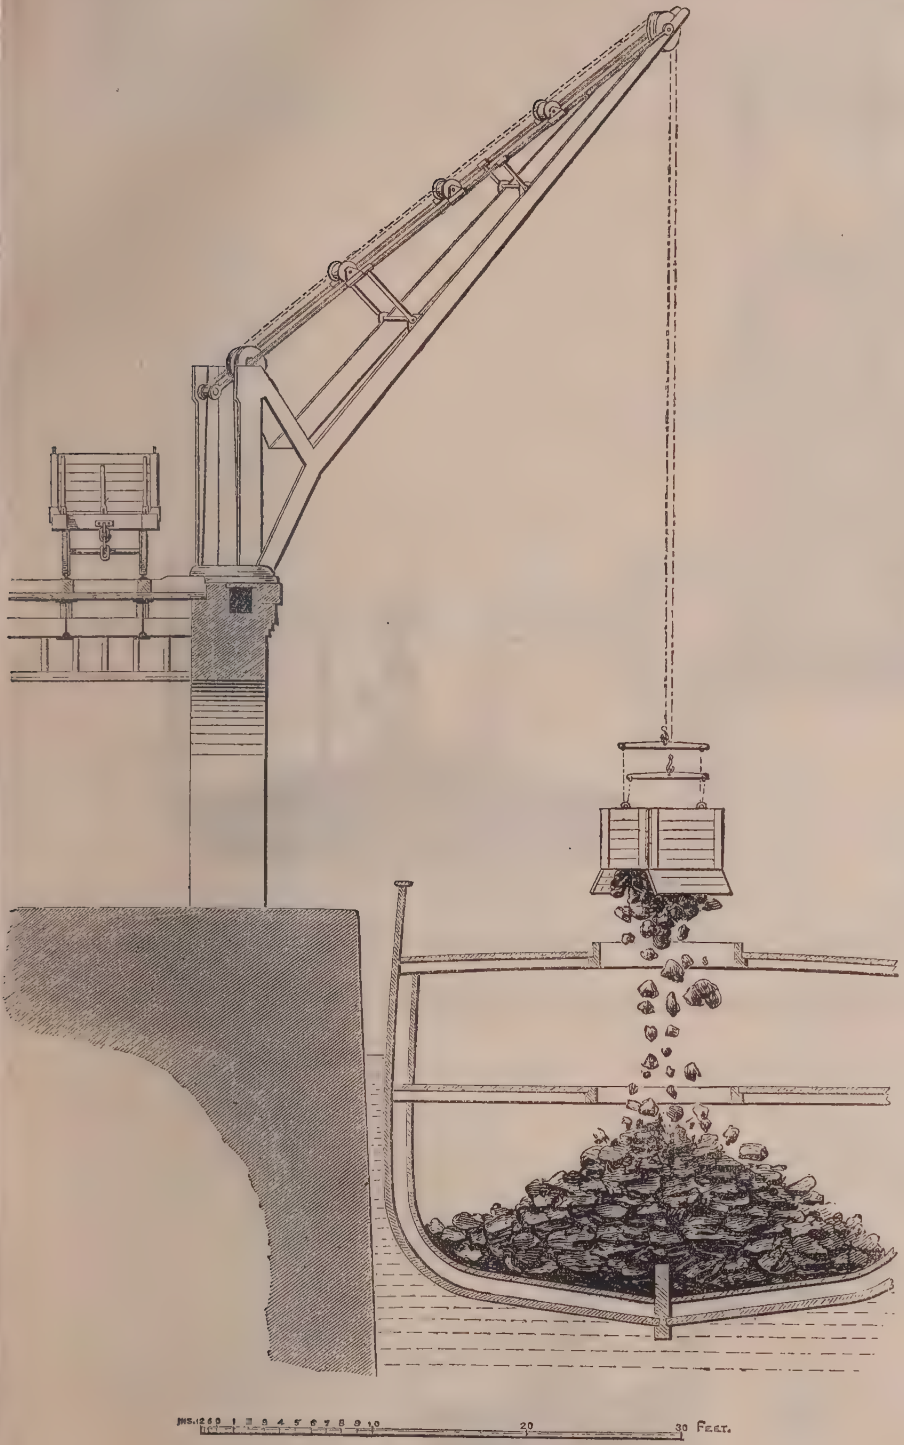
The crane, which loaded 363,000 tons in 1875 as against 73,000 loaded by hand tips, is worked by hydraulic pressure, and lowers the waggon-load of coal to the hatchway of the vessel, when the bottom of the waggon is opened and the coal is poured into the ship. The waggon cannot be lowered through the hatchway, as in the box system, so that the initial fall of the coal is the whole depth from the hatchway to the bottom of the ship, this fall decreasing as a cone is gradually formed, until the top of the heap is level with the lowest hatchway. It is then trimmed until the lowest compartment is filled, when the process is repeated. All the coal therefore in the lowest division of the vessel, supposing her to be a two or a three decker, must fall at least the distance from the uppermost to the lowest hatchway. Working at the quickest speed a crane can load 100 tons an hour.

The hand tips at the high level are used for shipping coal into flats; the coal by this method has a fall first from the waggon into the shoot, then a fall of about 6 feet at the turn of the shoot, and another fall from the end of the shoot into the vessel. The box system, as used at Swansea and Cardiff, exists also at Liverpool, but it is not largely resorted to.

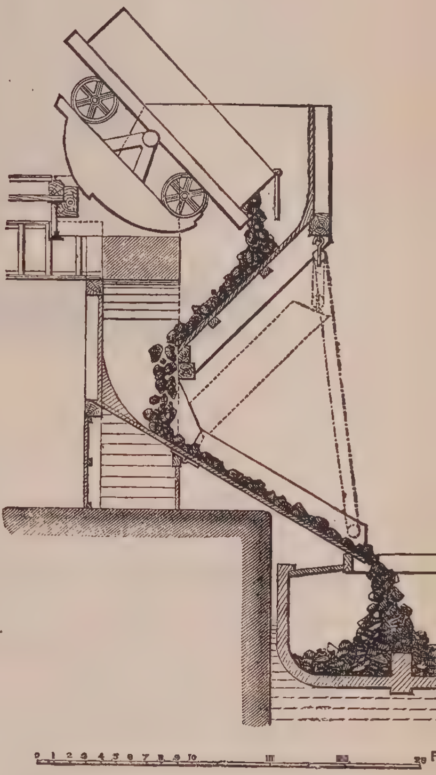
---

* These sketches, and those of the systems in use at Birkenhead, have been kindly forwarded to us by the secretary to the Mersey Docks and Harbour Board. Also some interesting statistics, relating to the shipment of coals from the port of Liverpool, which will be found in the Appendix, page 118.

No. 4.



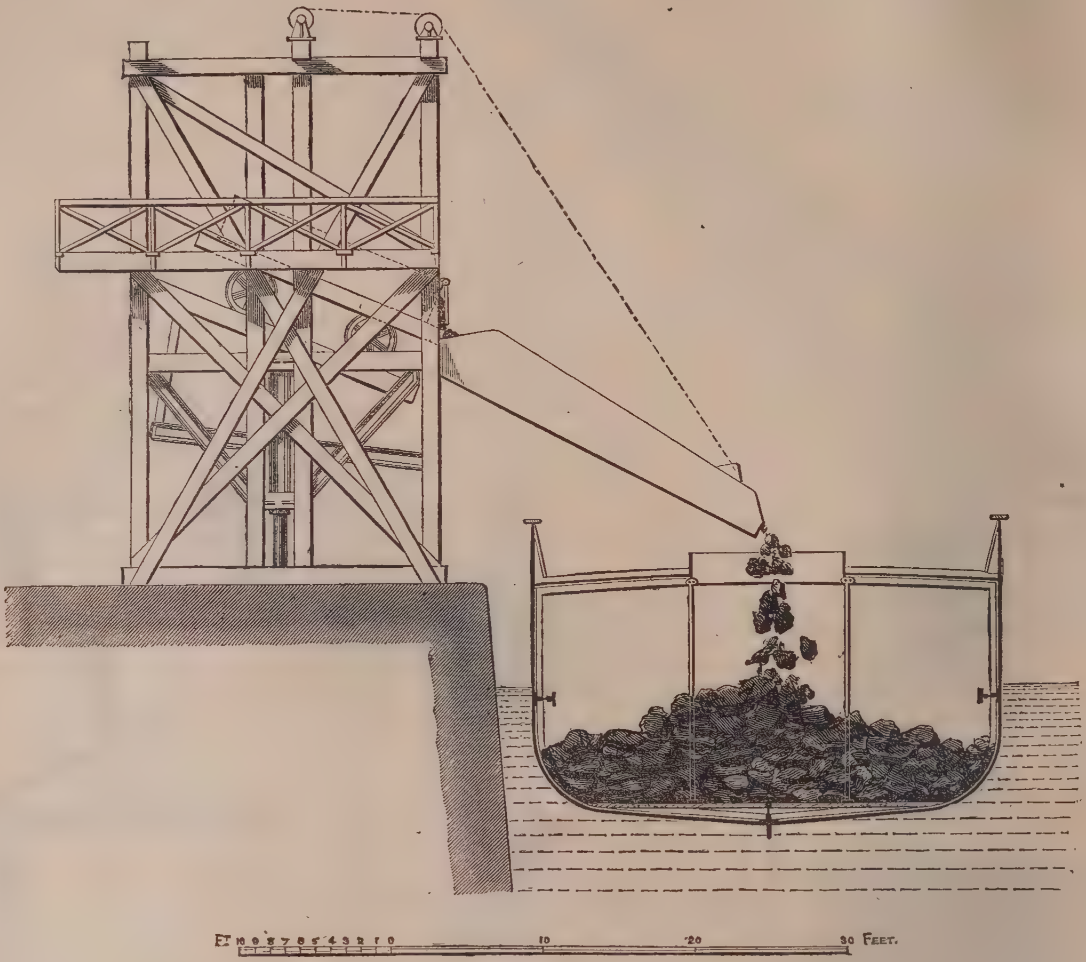
No. 5.



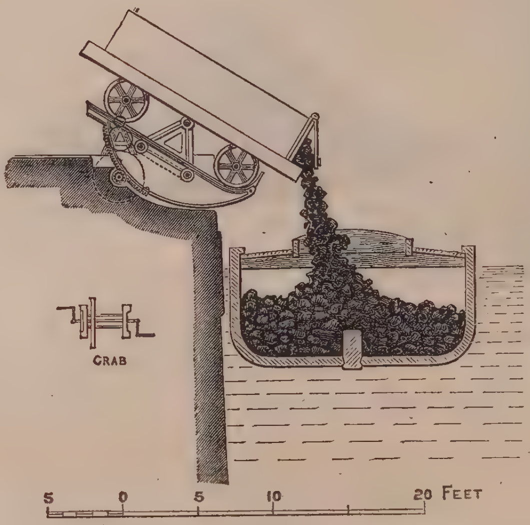
Systems of loading at Birkenhead.

At Birkenhead where the lines are on the low level, the Mersey Docks and Harbour Board appliances consist of hydraulic hoists and hand tips, of which the following are sketches:—

No. 6.



No. 7.



Hydraulic hoist.

The hydraulic hoist is somewhat similar in principle to that used in the Bristol Channel, but without the anti-breakage boxes. Only 77,000 tons were loaded by this method last year at Birkenhead, as against 363,000 shipped by the hydraulic cranes at Liverpool.

Hand tips.

The low level hand tips are only used for flats and lighters.

Loading by barrow.

Besides these methods upwards of 254,000 tons of coal were loaded during 1875 into sailing vessels by barrows.

By this method the coal is taken from the waggon in barrows which are lowered into the ship's hold, and there wheeled along planks to the place where the coal should be discharged, thus avoiding all the disturbance consequent on trimming and all serious fall of the coal. This is, however, by far the slowest process of loading, and we found that, to save the time and trouble required to lower the barrows into the hold, the coal was often discharged from the barrow down the hatchway.

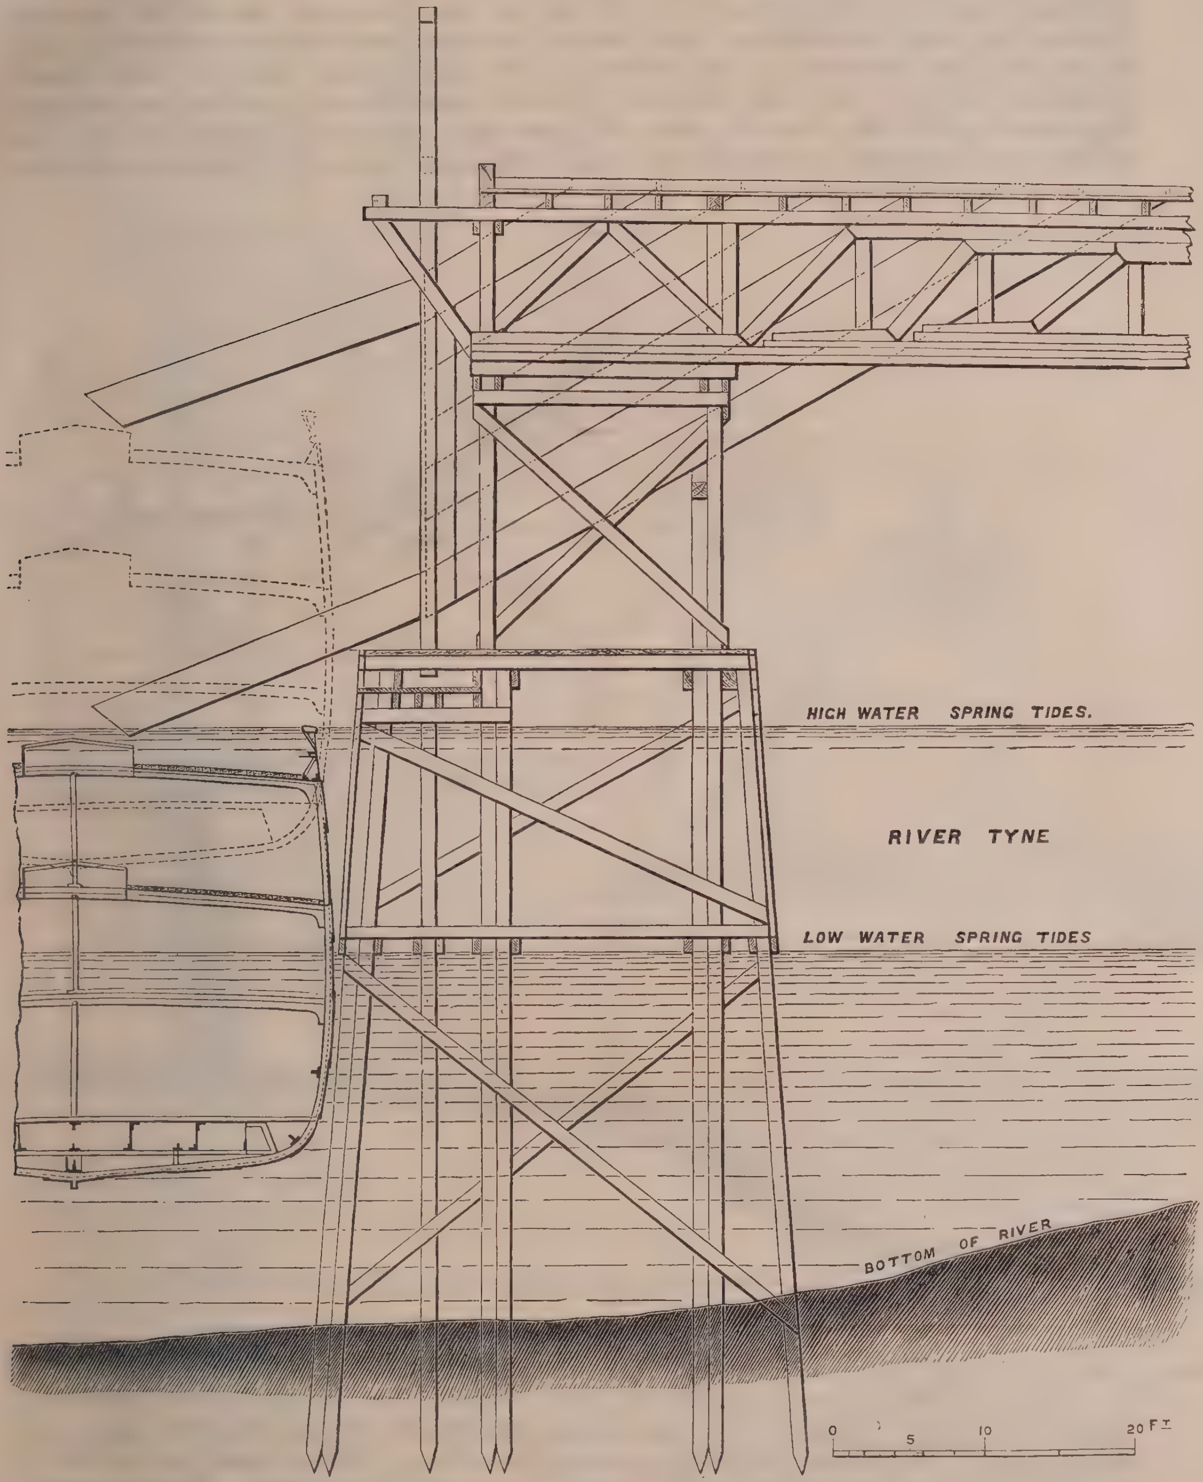
Systems of loading on the Tyne.

On the Tyne, the two systems in use are called the "spout" and the "drop."

The "spout.

The following is a sketch* of the coal staiths of the River Tyne Improvement Commissioners at Whitehill Point, and illustrates the "spout" system :—

No. 8.

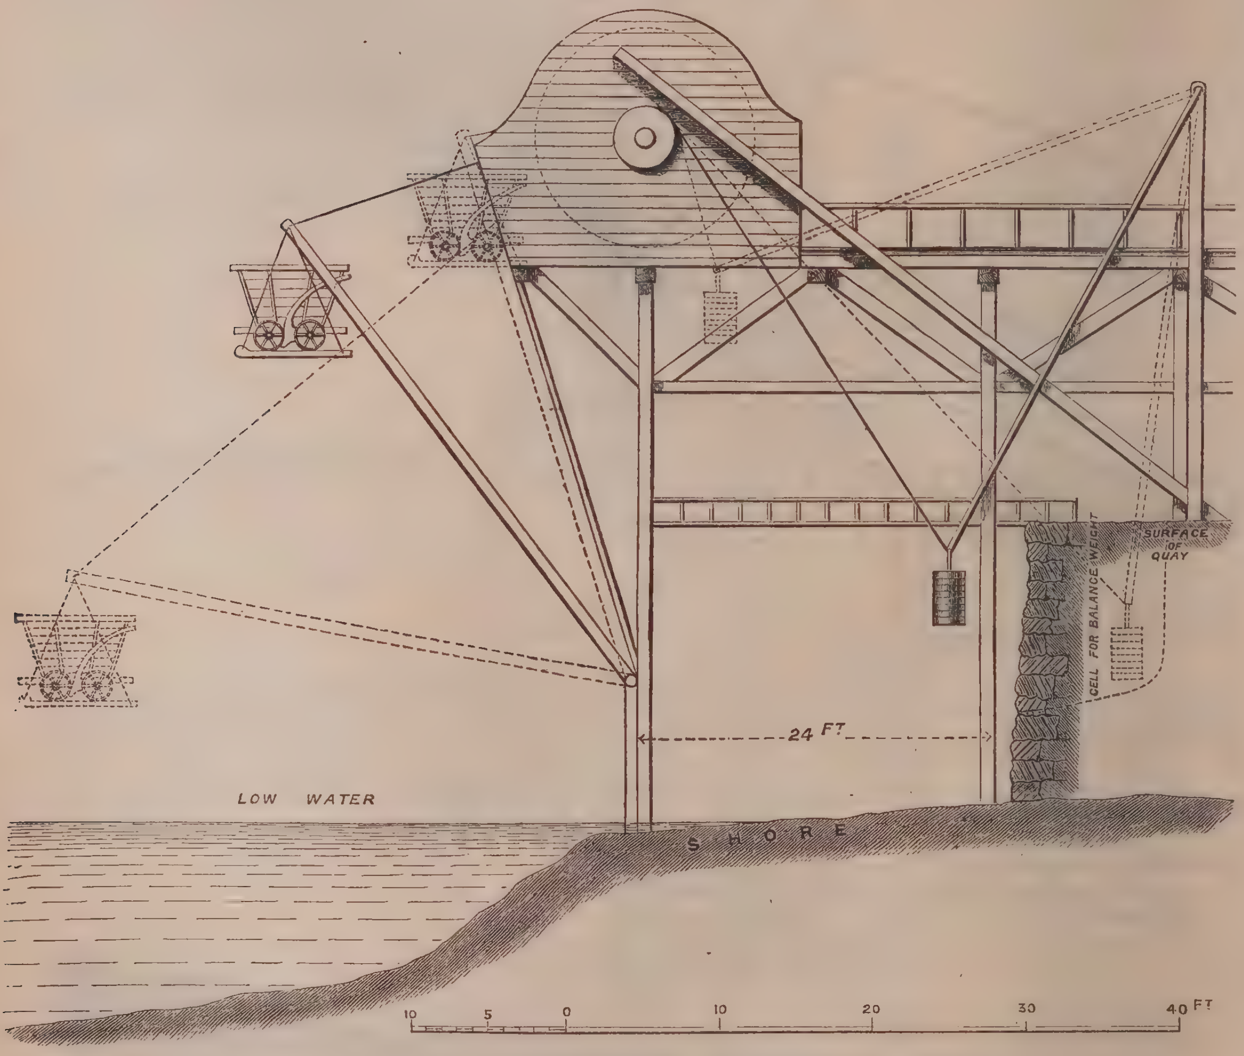


By this method a sliding shoot is fitted to the mouth of whichever of the seven spouts, represented in the sketch, the height of the tide, and the depth of the vessel in the water, renders most suitable for bringing the end of the shoot directly over the ship's hatchway. The waggon is then run over the entrance to the spout, and its bottom opened. The coal falls some three to five feet into the spout, slides down the incline and along the shoot a distance, varying according to the spout used, from 35 to 75 feet, and then drops from the end of the shoot into the ship's hold. The height from the line of rails on which the waggon stand to the ship's hatchway would vary according to tide from about 15 to 35 feet. The coal is not trimmed until a cone is formed reaching to the hatchway, when the fall from the end of the shoot becomes reduced to two or three feet. The trimmers then spread the coal as it is shipped, assisted by smooth steel plates, which they place on the sides of the cone. The anti-breakage boxes do not appear to be in use on the Tyne, and the fall of the coal forming this cone, especially of that forming its base, must be very considerable, the depth from the hatchway to the bottom of the hold being often in large vessels upwards of 20 feet. As in the shoots at the Welsh ports the end is in the first instance kept closed until the shoot is quite full, and then the coal is allowed to run out, sliding down the spout in a continuous mass at the same rate as it is filled in at the top.

---

* The sketches of the systems of loading on the Tyne were kindly forwarded to us by Mr. Philip Messent, engineer to the River Tyne Improvement Commission.

No. 9.



The "Drop." Of the "drop" system, illustrated above, there are only six or eight specimens on the river, and they are only adapted for small vessels. The system is being gradually superseded by the "spout." The fall of the coal from the waggon into the spout, and its subsequent disturbance during its passage down the spout and shoot, is avoided by the "drop," which lowers the loaded waggon to the ship's hatchway. In this system, as with the spout, the coal is not trimmed until a cone is formed rising to the level of the ship's deck; but, as the waggons cannot be lowered through the hatchways, the initial fall of the coal forming this cone is represented, as in the case of the spout system, by the distance from the coaming of the hatchway to the bottom of the empty ship.

Captain Steinson,* coal inspector on the Tyne and Wear for the Peninsular and Oriental Co., and for the Admiralty, India Council, and Crown Colonies, described a lowering apparatus formerly used at Newcastle as satisfactory in result, but it had to be given up on account of the aversion of the men to working it, there being some risk of accident unless it were carefully handled. Captain Steinson had since adopted a system of platform on the lower beams in order to break the fall of the coal.

Systems of loading on the Wear. The "Spout.

On the Wear the systems employed are the "Spout" and the "Gooseneck Drop." The following is a sketch† of the spouts at the new staith erected at Hendon dock.

It is approached by heavy concrete retaining walls, nearly 600 feet long and about 40 high. From the retaining wall the staith is carried on iron columns decked with rolled iron and creosoted timber. The kip of the staith consists of two lines of rails which provide standing for 350 tons of coal. The lines for the loaded waggons have a fall towards the first spout, where they join, and then rise as a single line to the end of the gearing. The line for the return of the empty waggons is a single line with a return fall, so that the waggons are worked entirely by gravitation. There are two spouts, each with five shoots, to allow for the shipment of coals at various heights, according either to the rise of tide or the size of the vessel. The centres of the two sets of shoots are 50 feet apart, but, by a simple arrangement, the two spouts into which the shoots discharge can be moved in a lateral direction either to the right or left, so that the distance between the mouths of the spouts may be varied from 30 to 70 feet, in order to meet the requirements of any ship's hatches. The height of the rails above the high-water level of the Hendon dock is 43 feet, the height of the opmost shoot is 31 feet 6 inches above the same level, the height of the lowest shoot being 18 feet 9 inches, the dock having a depth of water of 29 feet 6 inches. During shipment, a set of eight waggons containing 32 tons of coal are brought down to the spouts, and the contents of two waggons are discharged simultaneously into the two hoppers, so that 16 tons of coal are run down each spout at one and the same time. By this means the spouts are capable of shipping at the rate of 500 tons per hour.

---

* Captain Steinson has been coal inspector for the P. & O. Co. for over 14 years, and in 1864, 1865, and 1866 he inspected for the Egyptian Government. His evidence appeared to the Commission to result from long and valuable experience, and to deserve especial consideration.

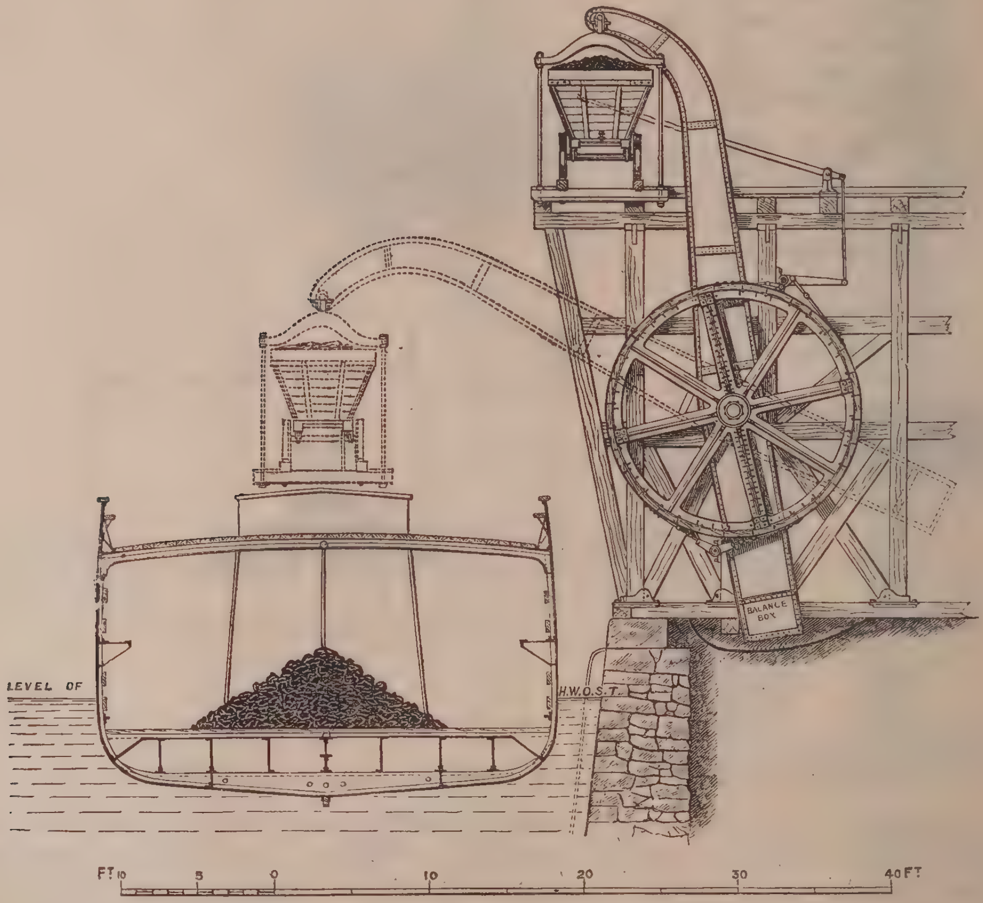
† We are indebted to Mr. Wake, engineer to the River Weir Commission, for the sketches of the systems of loading in use at Sunderland.

The breakage of coal by this system of loading must be very considerable, indeed greater even than by the tips, for when the waggon is tipped the coal runs with less force and fall from the end of the waggon into the spout or shoot than when it is allowed to drop in a mass through the bottom of the waggon into the spout. At Sunderland the fall from the waggon into the first shoot must be over six feet, and from the bottom of the waggon to the lowest shoot must be about 20 feet. The anti-breakage box or tub is used, as in South Wales, in the earlier stages of loading, for the formation of a cone of coal to lessen the breakage in the fall from the mouth of the spout into the ship's hold.

The "Gooseneck drop."

The "Gooseneck drop," of which the following is a sketch, is worked simply by the break wheels, and lever break, the weight of the loaded waggon taking down the drop to the distance required, where it is retained, by means of the break, until the waggon is emptied. The lower ends of the lever are weighted so as to be a little heavier than the empty waggon, which by this means is brought up again to the level of the rails. The capability of a drop is said to be about the third of that of a spout for the shipment of coal. Its effect as regards breakage would be the same as that of the drops in use on the Tyne.

No. 11.



Comparison of systems with regard to the breakage of coal.

Of all these methods, the evidence tends distinctly to show that the "tips" and "spouts" conduce most to the breakage of the coal. In the system of loading by hoist or by crane the fall from the bottom or end of the waggon into the ship's hold is as great as from the mouth of the shoot or spout; but the coal, until released from the waggon, is literally undisturbed, and the fall from the bottom or end of the waggon, as the case may be, into the spout, together with the concussion of the coal in its passage down the spout, is avoided.

Whatever additional breakage, however, has to be debited to the "tip" and "spout" systems on these accounts happens before the coal reaches the vessel, and is equal in its effect on the whole cargo, and though reducing the value of the coal, is of small importance with regard to spontaneous combustion, in comparison with the final fall of the coal into the ship's hold, an evil which attaches equally to both systems of loading, whether by spout or by crane.

In each system the fall of that portion of the coal which is first put on board, especially in large and therefore deep ships, is very considerable, and the consequent accumulation of small and crushed coal under the hatchways has, we believe, in many cases promoted spontaneous combustion.

Danger of accumulation of small coal.

It was to obviate, as far as possible, the breakage consequent on this fall that the anti-breakage boxes were introduced, and witness after witness advocated building a cone of large coal up to the hatchways, either by boxes or by baskets, in order to break the fall of the coal, and disperse the small coal as it comes down the spout. But even where a cone of average size coal is thus made, rising to the level of the highest hatchway, (which in a two or three decker seems hardly practicable,) still the continuous fall on this heap of the rest of the cargo, sometimes amounting to over 1,000 tons, gradually crushes or pulverises it. Moreover, as each load falls on this central heap, it is the large coal which runs down the sides and is trimmed away to the ends, while the smallest coal, fine slack and dust, clings to the heap where it falls, or gradually accumulates in a compressed mass under the hatchway. It is here that experience shows that spontaneous combustion generally originates; witness the cases of the "Oliver Cromwell," "Calcutta" "Euxine," "Pocahontas," and others.

Speaking of the "Oliver Cromwell," Mr. Price, a large shipowner, said that the coal fell "a very considerable height," and "was very much broken indeed." He continued: "I went into the hold of the 'Oliver Cromwell' when she was about half "loaded, and I noticed in the main hatchway, where the bulk of the cargo was coming "down, a great accumulation of small coal in a pyramidical shape, and I said to the "captain as I came up, 'I am thankful that I am not the owner of this cargo; "'there seems to be so much small in it.'" (Q. 1151). He added that the "Calcutta" and the "Euxine" (which were also burned) were loaded in exactly the same way.

In the case of the "L'Aqouhanna," loaded at Birkenhead, the captain said (Q. 2539), "The tip lifts a truck about 15 or 20 feet above the ship's deck; the coal runs in an "iron shoot, and by the time it gets into the hold it is smashed up, and a large body "of small coal always lies where it falls." Speaking of the cargo of the "L'Aqouhama" he said the coal having to fall a great height there was a great accumulation of small coal round the hatchways (Q. 2561).

Captain Cawkitt, the manager of the Liverpool Salvage Association said, "Most "of the burnings in the ships we have heard of have been under the main hatch, "and the bulk of the burnings have been in vessels that have been loaded under the "tips where the coal is broken, and where there has been a lot of small coal accumu-"lating round the main hatchway, and I believe in most instances the fire has been "proved to have originated about the main hatchway."

The evil of this accumulation of small coal was insisted on by many witnesses.

Mr. Cooper Rundell, accountant to the Liverpool Underwriters Association, stated, quoting from "Stevens on Stowage," that in South Wales it is the practice to dig out a quantity of small coal from the hatchway, after the vessel has completed her loading, and to replace it by larger coal, showing that there is a feeling that danger may arise from too large a surface of small coal.

Mr. Price, to whose evidence we have already referred, when asked whether he had any reason to believe that spontaneous combustion was more likely to occur in an accumulation of fine coal in coal cargoes, not only referred again to his own experience, but said that a shipmaster who had been in ships that had been on fire, and had attended three surveys of ships, that either came into Bombay on fire, or had taken fire while lying there with coal, told him that the fire in each case occurred about 5 feet from the skin of the ships in the region of the main hatchway, where there was an accumulation of fine slack to which he attributed the fires (Q. 1228, 1229); and though he acknowledges that the liability to breakage was to a certain extent got over, when once a cone was formed, he added, "I have always seen it "come up in a pinnacle of small coal to the very top, and as long as there is room "for it to run clear of the hatchways the big lumps of coal run down, and the small "coal generally culminates." (Q. 1290–1292.)

Mr. Hancock, of Bristol, said, "I think the danger of spontaneous combustion "arises from the small coal. I think the fire generally takes place in the hatchway, "underneath the drop, where the small coal is likely to accumulate" (Q. 1342 and 1353).

Mr. Scott, of the firm of Gillespy and Scott, read the following extract from a letter written by the master of the "Pocahontas," lost by combustion in 1874. "Four

"Boston ships have been burnt this season within two months of each other, and "the accounts given are about alike as to the cause of the fire. In most every case "ships have taken fire in the hatchways, where the fine coal is. If ships could be "loaded so as to avoid the fine coals collecting in the hatchways, and some means "taken to prevent the coals breaking up, I do not think fire would occur." (Q. 2093.)

This serious danger, of an accumulation of small coal under the hatchways, which attaches both to the "tip" ("or spout") and "crane," is avoided if the vessel is loaded either by the box system or by barrow.

Accumulation of small coal avoided in loading by box system or by barrow.

The box system was strongly advocated by Mr. John Glasbrook, of Swansea (Q. 2212–2218), and was also commended by Mr. Robert Hancock, shipping manager to Messrs. Charles Hill and Sons, of Bristol and Cardiff (Q. 1331–1335). And speaking of the barrow system, Mr. Cooper Rundell believed in an entire immunity from combustion in vessels so loaded (Q. 116 and 117), whilst he gave some significant statistics as to the increased use of the "tip" at Liverpool, and of the subsequent increase of casualties in shipments from that side of the Mersey (Q. 76).*

Comparing the system of barrows with that of tips, Mr. Price said, "I have loaded "vessels on two or three occasions from Birkenhead by tips before I became alive to "the advantage of the better mode of loading," (Q. 1211) and when asked what he considered the advantage of loading by barrow, said, "Hitherto I have not done it "voluntarily, I have done it because it was a stipulation in my charters that that "mode of loading should be adopted, in future I shall always adopt it, because I "think the cargo is more equally distributed, the small coal does not get into a mass "in the region of the main hatchways, which is the locality where according to my "experience fires usually take place" (Q. 1214). He admitted, however, that the system was a very slow and expensive one, enabling, even with plenty of hands, only 250 tons a day to be put on board, whereas by tips 1,800 tons could be put on board in 48 hours (Q. 1205 & 1210).

Rapidity in loading.

But rapidity in loading is of course an important consideration, not only as a question of time, but also of expense, as shown by Mr. Cooper Rundell (Q. 157 to 163).

Breakage of coals deteriorating to its value as well as conducive to combustion.

That the box and barrow systems are stipulated for in charters, and adopted by many shippers, although the process is in both cases much slower and generally more expensive than that of the tip or the crane, proves that the coal is far less subject to breakage when thus lowered into the ship. It is true that the Peninsular and Oriental Co., and others who use these methods, desire to minimize the breakage of the coal, not so much from any apprehension of spontaneous combustion, as for the purpose of maintaining the value of the coal. But in so doing it is clear from the evidence both of experience and of science that they also diminish the risk of casualty to their cargo from spontaneous combustion, since, apart from any accumulation of small coal, the less broken the coal is generally, the less liable it is to heat.

We are therefore of opinion, with reference to the subject of our inquiry, that, in all methods of loading, the chief aims should be to subject the coal to as little breakage as possible, and to avoid any accumulation of small coal in the cargoes.

Tendency to overrate injurious effect of wet on coal cargoes.

3. *Moisture*.—Most of the witnesses who have come before us have strongly condemned the shipment, or carriage, of coal in a wet condition, and their experience, in this respect, is, to a certain extent, supported by the scientific evidence to which we would direct very careful attention. It would appear that the wetting of certain kinds of coal, more especially those containing pyrites, is active in promoting spontaneous combustion; but the statements of some of the witnesses lead to the impression that moisture has been credited with cases of combustion beyond the sphere of its operation; while, from other passages of the evidence, it appears to us that the influence of the water, existing to a greater or less extent, in all coal before it has been brought to the surface, has not been sufficiently recognised.

4. *Through Ventilation*.—If this had been the only question referred to us, the urgent need for this inquiry would have been completely demonstrated by the result.

---

* From the statistics forwarded to the Commission by Mr. Cooper Rundell, which will be found in the Appendix, page 127, it appears that of the shipments from the port of Liverpool with 500 tons of coal and upwards, on voyages across the Equator or through the Suez Canal, in the years 1873, 1874, and 1875, 348 were loaded by tips, and 608 by hand. Among the 348 loaded by tips 21 casualties occurred, while only 4 casualties are recorded among the 608 loaded by hand.

Conflict of evidence as to through ventilation.

The evidence before us of those connected with the shipment of coal, either as shipowners, shippers, or masters, shows a decided want of information as to the elementary causes of spontaneous combustion, and therefore of the real source of danger in through ventilation as explained in the scientific paper attached to this report; hence arises a considerable conflict of opinion.

Real danger of ventilation not understood by its opponents.

Even those who from extensive personal experience, had arrived at the knowledge that ventilation through the body of the coal was, in effect, rather injurious than otherwise, based their opposition to it solely on the grounds that it "fanned the flames" after ignition had taken place, or that the wood, of which the ventilators were generally made, ignited at a lower temperature than the coal, and thus hastened the catastrophe; but they always expressed their conviction that such ventilation could not but tend to prevent heating in the first instance.

Advocates of ventilation.

On the other hand, some thorough advocates of ventilation have given evidence before us.

When their views were based on personal experience, we think that the evidence of these witnesses showed a tendency to credit all cases of immunity from fire to the ventilation, and to attribute all cases of casualty in ventilated ships either to other causes, or to the inadequacy of the ventilation itself, not because they realised the fact that partial ventilation was an element of danger, but because they considered that the amount of ventilation, though beneficial as far as it went, had not been sufficient to keep the temperature low enough.

Spontaneous combustion and explosion confused.

Where ventilation was advocated on less practical grounds than those of experience, we observed a strong tendency (and this remark applies to the bulk of the evidence on this subject) to confuse spontaneous combustion and explosion. Many of the witnesses were under the impression that both results were produced by the same causes. For instance, Mr. William Darley, a gentleman employed by the Board of Trade as assessor in the cases of the "Zeno," "Berwick," "Marie Lee," and "Herbert Graham," on being asked (Q. 2812) "As to green coal, how does that produce *spontaneous combustion*?" replied, "When it is wrought from the pit it is full of gas; if it " is exposed to the atmosphere previously to being shipped, some of that gas is " emitted that would be otherwise retained, but when confined it becomes dangerous, " and ultimately heats."

We believe that this confusion of ideas may have caused many witnesses to treat ventilation as a safeguard against spontaneous combustion, having had reason to regard it as a safeguard against explosion; and a want of knowledge of the conditions productive of explosion, lead them, as in the case of Mr. Darley, to consider that this ventilation, even to guard against explosion, should be carried down through the body of the cargo.

Ventilation generally considered harmless, if not beneficial.

But between the thorough opponents and the consistent advocates of ventilation, the evidence shows a certain proportion of shipowners, masters, and coal shippers, who express themselves as having "no faith in ventilation," but as considering that it " could not do any harm." Many of the witnesses representing this class informed the Commission that they only ventilated their ships to satisfy other interests concerned. Thus, Captain Scurr, of the "Brenhilda," a thoroughly ventilated ship, said (Q. 308 and 309), "I would as soon go to sea with a ship that was not furnished with " ventilators as with a ship that had them."

Captain Kennedy when questioned about ventilation said, "I do not think it does " much good" (Q. 2546); and again, "I doubt the practical worth of ventilation at " all" (Q. 2554), nevertheless he habitually ventilated under advice from his owners " who considered it beneficial."

Again, Mr. Price, a large shipowner, when asked (Q. 1235) "Would the object of " adopting that mode of ventilation be to guard against fire, or to guard against explo- " sion," replied, "It would be rather to satisfy my underwriters than to guard against " anything; for I tell you candidly, that having been free from casualties, I simply " adopted that which the underwriters surveyors, and such like people, recommended " without looking at it critically or carefully at all. The first thing an underwriter " says to you when you are insuring a cargo of coals is, "Will your friends see, or " will you see, to the ventilation? They make a special point of seeing to the " ventilation."

Mr. Thomas Beynon, shipowner and coal merchant at Newport, said, "Personally " I have no faith at all in the ventilation of smelting coal," (Q. 1395); but when was suggested to him that he had subsequently in his evidence recommended a particular system of ventilation, he replied, "No; I stated the system I adopted, and I think in ships which I loaded at Liverpool we were obliged to adopt that plan by the Board of Trade," (Q. 1495.) In this, howerer, he was mistaken, the Board of Trade having laid down no absolute rule on the subject.

Captain Steinson, coal inspector at Newcastle for the Admiralty, India Council, Crown Colonies, and the Peninsular and Oriental Company, stated "that all Liverpool ships must be ventilated." (Q. 1598.) Later he said, "It is a curious thing that " none of the North country ships that I have had to do with, that have not been " ventilated, have been burnt. I was talking to an old captain who told me that he " had never had a casualty happen to a ship except in one case, and that was the " only time he ever ventilated the ship." (Q. 1698.)

Referring to the case of the "Oliver Cromwell," which was burnt, Captain Steinson said, "The 'Oliver Cromwell' was ventilated. The captain came and asked me how " I wanted the coal ventilated, and I said 'I do not want the coal ventilated at all, " 'it is no business of mine;' on that he said, he was obliged to ventilate by the " charterparty. I said, 'Then ventilate according to the charterparty, but as far as " 'my own opinion goes I would not ventilate at all.' He further said, 'The owners " 'say she must be ventilated.' 'Then,' I said, 'Ventilate according to the owners' " instructions.' So he did ventilate according to the owner's instructions with shafts " up and down each hatchway, connected with fore and aft shafts." (Q. 1632.)

Further, Mr. Cooper Rundell, of the Underwriters' Association of Liverpool, gave evidence that "The Underwriters' surveyors at Liverpool have recommended a special " system of ventilation," and that "These surveyors go round the docks and give " information, amongst other things, to the underwriters, respecting the mode of " ventilation adopted." (Q. 91.)

Captain Sandeman, formerly surveyor at Liverpool to the London Salvage Association, and now surveyor under the Marine Department of the Board of Trade, said, with regard to ventilation, "I should say that under all circumstances it is desirable." Q. 2654.) And having explained in detail the various systems employed at Liverpool, he said, "Many shipowners in Liverpool hold that ventilation is of no advantage " whatever, and it was only under pressure that they were disposed to adopt it." (Q. 2647.)

The evidence given by letters on this subject from all parts of the kingdom in answer to the printed circulars issued, of which an analysis is appended, also shows the same prevalence of the adoption of ventilation, often against the convictions of the shipowners and masters concerned.

Injurious effect of recommendations made by courts of inquiry held by Board of Trade.

Such evidence leads us to fear that the statutory inquiries held during the last few years under the Board of Trade, with uniform result in favour of ventilation, have not been so ineffectual as that Department believed, but that, on the contrary, they have proved powerfully influential in a dangerous direction.

The practice of ventilation has greatly increased during these years. Charterers, insurers, and surveyors on behalf of Government, or of underwriters associations, or of shipping companies, are the classes most likely to be influenced by the repeated verdicts of such courts of inquiry; and the evidence goes far to show that many vessels, which if left to their owners or masters would have probably gone to sea unventilated, have, under pressure from these quarters, adopted systems of ventilation that cannot but have added to the risks they incurred.

Evidence against ventilation furnished by the cases of vessels that have suffered combustion.

Turning from the evidence of opinion to the evidence of fact with regard to ventilation, we find that the scientific conclusions expressed by Dr. Percy and Professor Abel receive confirmation.

Of the 70 ships that suffered in 1874, none are reported as not having been ventilated, while 38 are distinctly stated to have been ventilated, 35 of them being vessels over 500 tons. But the most startling illustration is furnished by the cases of four vessels "the Euxine," "Oliver Cromwell," "Calcutta," and "Corah." These ships, to which reference was made by several of the witnesses who appeared before us, were loaded under the tips at Newcastle, at the same time, with the same coal, and from the same seam, sometimes one ship being under the tip and sometimes another. They were each carrying from 1,500 to 2,000 tons of coal. The "Euxine," "Oliver Cromwell," and "Calcutta" were bound for Aden, the "Corah" for Bombay. The first three ships were thoroughly ventilated, the fourth was not ventilated at all. The "Euxine," "Oliver Cromwell," and "Calcutta" were all totally lost from spontaneous combustion. The "Corah" carried her cargo safely to Bombay.

Since this Commission has been sitting further, evidence in this direction has been supplied by the vessels "Theresa" and "Anglia." The "Theresa" (704 tons) sailed from Birkenhead for Rangoon with 920 tons of coal in September 1875, and became a total loss from spontaneous combustion when she had been at sea a little over two months. She was very extensively ventilated, having square venetianed deal ventilators in each hatch to the keelson, and a trunk-way on each side of the keelson, and three rose mushroom ventilators in each hatch. The following is an extract from a letter from her owner, Mr. Henry French, of Liverpool:—"When I heard of the loss " of the 'Theresa' I had another vessel (the 'Anglia,' 525 tons reg., classed A.E. 1 " Eng. Lloyd's) beginning to load 630 tons of the same kind of coals for Havanah. " The captain decided he would have no ventilation, and went without any. She " sailed 29 Jan. /76, and was 69 days on the passage, being 28 days before getting " clear of this land. He reported his coals very hot when discharging, but no signs of " fire, and the top of the coals seemed to be coated with a kind of scum like sulphur. " During the voyage his hatches were kept off when practicable. I mention the " above on account of the coals being from same pit, and being just the same time on " board as the 'Theresa's' cargo. One ship was ventilated, the other not."

We have also personally inspected the methods of ventilation adopted at the various coal-shipping ports, and that inspection has further convinced us how feeble such systems are for any purpose, except for the introduction into the coal of one of the elements of spontaneous combustion.

Systems of ventilation inspected by Commissioners.

The most ordinary method of ventilation consists of shafts, about 2 ft. square, nearly always constructed of wood, and in the majority of cases venetianed, which pass down through the body of the coal from the hatchways to the bottom of the vessel, where they lead into a box shaft running along the keelson or into a space below the platform. Sometimes these shafts are carried up through the hatchways and fitted with cowls, so as to form an up-cast and a down-cast for the current of air passing through them, but they are often only brought to the level of the deck, and are therefore closed whenever the hatches are on.

Some valuable papers, forwarded with great courtesy to the Commission by Mr. Henry S. Poole, inspector of mines for Nova Scotia, on the subject of spontaneous combustion in the coals of that district, contain some striking and conclusive evidence on the injurious effect of ventilation as applied to coal on shore. We feel much indebted to Mr. Poole, both for the expression of his own views on this subject, and also for the trouble he has taken in collecting for us the experience of those whose papers he has inclosed. (See Appendix.)

Papers from Nova Scotia.

We are therefore fully of the opinion of Dr. Percy and Professor Abel that, "the " evidence which has been submitted to the Commission on the subject of ignition " of coal cargoes, bears out generally the conclusion that it is inadvisable to attempt " *through ventilation* of cargoes in coal-laden ships."

Through ventilation condemned by scientific evidence.

5. *Provision for testing Temperature of Coal Cargoes.*—The papers forwarded from Nova Scotia by Mr. Poole, the Inspector of Mines, to which allusion has already been made, advocate the use of thermometers, to be lowered, by means of metal tubes, passing into the body of the coal, in order to test and register its temperature; and by this means some interesting statistics, which he incloses, in connection with the heating of coal in store, were obtained. Mr. Wright, the engineer-in-chief to the Admiralty, described to us, in his evidence, a similar plan adopted by the Government in their coal stores at Jamaica, and in the coal bunkers of Her Majesty's ships.

The use of thermometers recommended for testing temperature of cargo.

Mr. Robert Hancock, shipping manager to Messrs. Charles Hill and Sons, of Bristol and Cardiff, in his evidence on the case of spontaneous combustion in "Her Royal Highness," said, "We always instruct the master to ascertain the heat of the hold with the thermometer" (*Q.* 1326.) A registration of the temperature by means of thermometers, was advocated by other witnesses, among whom was Captain Steinson, who stated that he was very careful, when commanding a coal-laden ship, to observe the temperature every day, but that it was not customary to do so among the masters of coal ships.

Papers from Nova Scotia Admiralty and other evidence.

6. *Explosions.*—We have not given any statistics on the subject of explosions,* because any return of explosions at sea would give a very inadequate idea of the extent of this evil, many, if not the majority, of these cases occurring in dock, or in harbour, sometimes even before the loading of the cargo is completed.

No reliable statistics as to explosions.

Mr. Beynon, in answer to the question,—

"Do you know any instance of explosion having occurred on a coal ship?" said,

---

* Particulars however of certain cases of explosion, forwarded by the Board of Trade and by the Admiralty, will be found in Appendix II. and III., pages 4 and 60.

"I have known several in Cardiff, but I have not inquired into the particulars. The "mate of one ship, after the ship had been loaded, took a lighted candle into the "hold and an explosion occurred. I do not know the particulars. The ship had "been loaded four or six hours." (Q. 1491.)

And Mr. Charles Tully, a shipowner in Newcastle, when asked as to his experience of explosion from gas, replied :—

"I have known two or three instances on the Tyne, where after the gas coals had "been loaded and the hatches had been put down, immediately the vessel blew up "altogether, that is to say, within two or three hours afterwards. In those cases "the vessel had not begun her voyage, but the hatches had been put down, and the "coals being full of gas they caused an explosion." (Q. 444.)

The danger of explosion is much greater in some kinds of coal than in others, and there is more risk and injury to life from these catastrophes than from spontaneous combustion, because they occur too suddenly to admit of provision being made for personal safety.

But, on the other hand, it is much easier to provide against the occurrence of explosion than of combustion.

We have, under another head, shown how prevalent is a confusion of ideas between these two causes of casualty, and it cannot be too clearly understood that they originate from entirely distinct causes inherent in the coal.

It should also be borne in mind that the gas, which by its mixture with oxygen is productive of an explosive atmosphere, is a light gas, which will readily find its way to the surface of the coal.

Surface ventilation recommended to prevent explosion.

All it requires therefore, is to have free and constant egress from the surface of the coal into the open air, and the majority of the casualties seem to occur from making the gas dependent for this egress upon the hatchways, which, in the event of rain or heavy weather, are liable to be covered and battened down. The gas then accumulates between the surface of the coal and the deck, and, mixing with the air with which it is confined, forms an atmosphere which only needs the application of a flame to explode.

Every coal-laden ship should therefore be fitted with shafts or ventilators piercing the upper deck, but not carried down on to or through the coal, with cowls always trimmed so as to form a downcast and upcast for the current of air, which would then pass continuously, and in all weather, over the surface of the coal, carrying with it any explosive gas as fast as it is evolved.

Objections to carbonic acid gas as a means of extinguishing fire.

Steam or water recommended.

7. *Means for extinguishing Fire.*—Several methods for generating carbonic acid gas and applying it to the ignited portions of a coal cargo, have been proposed for our consideration. We consider, however, that although this gas might be useful, by excluding atmospheric air (which is essential to support combustion), yet it will not, as water does, exert any very sensible cooling effect; which is a point of vital importance in the case of a considerable mass of ignited coal. We are of opinion that water and steam are the only agents practically available for the purpose of extinguishing fire in coal cargoes.

Summary.

Having completed our inquiry into the various questions embraced by the terms of the reference to us, we beg to lay before Your Majesty a summary of the conclusions at which we have arrived :—

1. That certain descriptions of coal are intrinsically dangerous for shipment on long voyages.
2. That the breakage of coal in its transport from the pit to the ship's hold, the shipment of pyritic coal in a wet condition, and, *especially*, *ventilation through the body of coal cargoes*, conduce to spontaneous combustion, even though the coal may not be unfit for conveyance on long voyages.
3. That spontaneous combustion in coal cargoes would be less frequent, if regard were had by shipowners and underwriters to these facts.
4. That when coal is being carried on long voyages the temperature in the various portions of the cargo should be tested periodically by thermometer, and registered in the log.

5. That, with a view to guard against explosion, free and continuous egress to the open air, independently of the hatchways, should be provided for the explosive gases, by means of a system of *surface* ventilation, which would be effective in all circumstances of weather.

6. That in order to make known the descriptions of coal liable to combustion, the Inspectors of Mines should be instructed to hold inquiry into all cases of spontaneous combustion occurring in cargoes of coal taken from their respective districts; exporters being required always to record on their specifications the denomination of the coals forming the cargo.

7. That no additional legislation with reference to the conveyance of coal by sea is required, unless for the purpose of giving effect to our proposals with regard to the inquiries by Inspectors of Mines, and to the fuller specification of coal entered outward at Her Majesty's Customs.

Paper by Frederick Augustus Abel, Esq., F.R.S., and John Percy, Esq., M.D., F.R.S.

The so-called spontaneous development of heat which occasionally takes place in coal, is due to chemical changes which certain substances occurring in it undergo through the agency of atmospheric oxygen, and which are liable to acceleration by some conditions attending the storage or transport of coal.

The substances, the oxidation of which is attended by the development of heat, are iron pyrites (and possibly some other combinations of sulphur), and some carbo-hydrogen compounds, forming part of the coal itself, which are comparatively readily oxidisable.

Iron pyrites is of almost universal occurrence in coal. The condition in which it exists differs considerably in different kinds of coal; in some it is distributed so as not to be detectable by ordinary inspection, in others it is in form of more or less conspicuous laminæ of a brass yellow colour; occasionally small distinct crystals of cubical form and bright metallic lustre are observed, and not unfrequently it is found in nodules (known as "brasses") and layers of considerable dimensions.

Iron pyrites, a compound of sulphur and iron known as disulphide of iron, occurs in the mineral kingdom in two crystalline forms, which are identical in chemical composition. Pyrites vary greatly as regards their stability or their liability to undergo oxidation by contact with the atmosphere. Some, after remaining unchanged during long periods of exposure, will undergo oxidation without any immediately apparent inciting cause. Others are perfectly stable, and with others oxidation follows with more or less rapidity upon their exposure to the atmosphere.

The presence of moisture in air promotes the oxidation of pyrites; it does so apparently by bringing the atmospheric oxygen into more intimate contact with the surfaces of the oxidisable material. Similarly, the absorption of moisture by mineral substances of laminated or porous structure, through which pyrites are disseminated, promotes the oxidation of the latter by bringing the atmospheric oxygen, which is dissolved by the water, into more intimate contact with the oxidisable material.

Thus, the oxidation of pyrites in alum schist is accelerated, in the manufacture of alum therefrom, by occasionally watering loose heaps of the mineral which are piled in such a manner that the access of air to the interior can be regulated.

The oxidation of pyrites (as in most instances of chemical action) is accompanied by the development of heat, which may accumulate to such an extent as to lead to the ignition of highly oxidisable constituents of minerals through which it is distributed. Heaps of alum schist exposed to the air and moistened will become heated to an extent to lead to the ignition of the carbonaceous constituents of that mineral, and similarly coal, through which pyrites are disseminated, may become heated to the point of ignition by the oxidation of pyrites disseminated through it.

Sulphur exists in coal in other forms of combination than that of iron pyrites. Thus sulphate of lime is occasionally disseminated through coal; the existence of sulphur in this form cannot give rise to the development of heat, as it is already in the completely oxidised or burnt condition; however, so far as is known they have not been found to possess any liability to spontaneous heating by oxidation. Some descriptions of coal or shale have been found to contain sulphur in somewhat considerable quantity in combination with carbon and hydrogen. An example of this is furnished by the so-called "resiniferous shale" occurring in Tasmania, which has been found to contain as much as five per cent. of sulphur in combination with carbon and hydrogen.

So far as is at present known, the spontaneous heating of coal is not ascribable to any tendency of such sulphur combinations to oxidation by atmospheric agency.

Pyrites appear therefore to be the only sulphur combinations occurring in coal which by their oxidation, promoted by the presence of moisture and by mechanical conditions favourable to the accumulation of the heat developed by such oxidation, are liable to give rise to the so-called *spontaneous ignition* of coal.

Coal varies considerably not only in chemical composition, but in structure, some varieties being comparatively open and porous, others compact or laminated, and very friable or readily broken up.

Carbon in a finely divided or porous condition has the property of absorbing and condensing within its pores large volumes of certain gases, among which is oxygen.

Thus, wood charcoal which has been recently produced, or which has been freshly heated sufficiently to expel moisture and gases which it may have absorbed, will condense within its pores more than nine times its own volume of oxygen, and seven times its own volume of nitrogen, which it is capable of absorbing by exposure to the air.

The condensation of a gas by a porous body is attended by the development of heat, proportionate to the extent of that condensation. Moreover, the tendency to oxidation which carbon, and certain carbon-compounds existing in such a substance as charcoal, possess, is favoured by the condensation of oxygen within its pores, whereby the very intimate contact between the carbon and oxygen particles is promoted. Hence the development of heat and the establishment of oxidation occur simultaneously; the latter is accelerated as heat accumulates, and chemical action is thus promoted and may in course of time proceed so energetically that the carbon or carbo-hydrogen particles may be heated to igniting point.

A good illustration of this action is afforded by the very porous charcoal prepared for the manufacture of gunpowder. It has to be protected against rapid access of air for some considerable time after it has been removed from the carbonising retorts (by transferring it at once from the retorts to metal receptacles which are kept tightly closed for a number of days), otherwise the charcoal, though it may have been allowed to cool down perfectly, will speedily become heated upon exposure to air, by the action above explained, to such an extent as to ignite spontaneously. Even after the stick charcoal no longer exhibits any tendency to heating when exposed, its pulverisation by grinding has still to be delayed; otherwise, when the absorption and condensation of oxygen by the internal portions of the pieces of charcoal become favoured by the reduction of these to a fine state of division and the consequent exposure of large surfaces to the air, ignition of the charcoal will take place. (Instances of such ignition upon the mill beds at powder works are not unfrequent.)

The spontaneous ignition of oiled cotton or silk waste, or cloths, which is of not unfrequent occurrence, affords another illustration of the manner in which the heat developed by the action of atmospheric oxygen upon readily oxidisable substances, consisting chiefly of carbon and hydrogen, which are exposed to that action under conditions very favourable to it, will readily accumulate to an extent sufficient to give rise to ignition. The porous cotton or silk waste serve, in such cases of spontaneous ignition, as vehicles for exposing the readily oxidisable oil or grease in a finely divided condition to the air, and thus favouring its rapid oxidation.

The foregoing explanation of the manner in which the spontaneous heating and eventual ignition of certain carbonaceous substances by the action of atmospheric oxygen are brought about, has a direct bearing upon the spontaneous ignition of coal. The more porous and readily oxidisable portions of coal, which are known to be more or less largely disseminated through seams from different localities, undergo oxidation by absorption of atmospheric oxygen, and by the exposure of large surfaces to its action, and the heat developed by that action will accumulate under favourable conditions to such an extent as soon to hasten the oxidation and the consequent elevation of temperature, until some of the most finely divided and readily inflammable portions actually become ignited.

The breaking up of the coal which occurs for a more or less considerable extent before and during its shipment obviously favours the absorption of oxygen, and consequently increases a tendency to heating by the action above described.

In a series of valuable experiments on the weathering of coal, by Richters and others, it has been demonstrated that a considerable quantity of oxygen is absorbed by freshly gotten coal, and that carbonic acid and water are evolved from such coal after absorption of oxygen, while a portion of the oxygen absorbed is fixed by the formation of some solid oxygenated compound in the coal. Spontaneous oxidation of coal by the oxygen absorbed from the air is therefore satisfactorily established and is unquestionably one, if not the chief, cause of the spontaneous heating of coal.

Spontaneous ignition of coal, when due to the oxidation of the porous and readily oxidisable carbonaceous substances occurring in coal does not appear to be favoured by the presence of water in the coal or by its access to a cargo; on the contrary, these portions, by becoming wet, would have their pores more or less filled with water, and their power of absorbing oxygen would be proportionately diminished; hence the presence of water must be antagonistic to the oxidising action of the latter in many instances, though, when iron pyrites is present, it may promote or accelerate spontaneous heating as already pointed out.

The gases which are occluded (or confined in a more or less condensed condition) in coal, vary considerably in quantity and composition in different kinds of coal, and they also gradually undergo various changes in composition by exposure or keeping of the coal.

Their chief inflammable constituent is marsh gas, and it is to the admixture of this gas with a *considerable* volume of air that *explosions* are due in freights or stores. In pits where explosions are liable to occur, the gas escapes either with more or less rapidity and force from fissures ("blowers"), or gradually from the freshly exposed surfaces of coal seams. When coal from such pits is brought to the surface it continues slowly to evolve inflammable gas for some time afterwards, especially if the coal be in large masses or stored in compact heaps.

If facility is not afforded for the ready escape or removal into the open air of the inflammable gas emitted from the coal composing a cargo or contained in bunkers on board ship, the spaces between the masses of coal, or any partially confined spaces not occupied by the coal but in close proximity to or communication with it, will in time become filled with a mixture of the gas with the air in those spaces, which, unless the former be present in very small proportions, would explode on the approach of a flame to it, and with a violence depending upon the proportion which the air bears to the inflammable gas which has become diffused through it.

As the application of flame (or of a body raised to a high red heat) is indispensable to the ignition of mixtures of air with the inflammable gas evolved from coal, it is obvious that *explosions* cannot occur spontaneously from this cause on board ship, but must be brought about by the accidental or incautious approach of a light to localities where the coal is stored, or where the explosive mixture is likely to penetrate.

If coal, from seams which are charged with marsh gas, is placed on board ship shortly after being raised from the pit, there is obviously great liability to the formation of an explosive atmosphere in the hold or bunkers, or spaces communicating with them, and every possible means should in such cases be had recourse to for facilitating the escape of gas from the coal into the open air.

But, as the gas requires a large admixture of air to render it violently explosive, it is obvious that any attempt to ventilate the coal by passing or drawing air into the *body* of the freight would be most likely to favour the production of a violently explosive mixture of gas and air. The only useful application which might be made of any special means of ventilation with a view to diminish the risk of *explosions* would be to pass a current of air *over* the coal and immediately into the open air, so as to accelerate the escape and removal of the inflammable gas.

As regards the application of ventilation with a view to reduce the liability to spontaneous *ignition* of a cargo of coal, the only useful object which could *possibly* be aimed at by ventilation would be the rapid abstraction of heat developed in the coal (by chemical changes set up as described) by causing cool air to circulate freely and rapidly throughout the *body* of a mass of coal. The attainment of such a result, even by powerful means of artificial ventilation, elaborately applied, and with the coal in the mechanical condition most favourable to its free permeation by air, appears, to say the least, very doubtful, and there can be no question that any system of ventilation practically applicable on board ship would fail to attain such a result, even disregarding the fact that the mechanical (finely divided) condition of much of the coal constituting a cargo is quite antagonistic to the free passage of air through its mass.

It does not appear practicable, therefore, to apply ventilation with any prospect of guarding against the accumulation of heat in some portion of a cargo of coal.

Such circulation of air as may be established even in the less compact portion of the cargo is not likely to have any valuable cooling effect, and the circulation, if there be any, must be very feeble among the more closely lying masses of small coal, so that heat, if developed in these, will accumulate undisturbed. Indeed, its development would possibly be favoured by the fresh supply of oxygen which a gradual replacement of the air surrounding those parts would convey, so that a period would be reached sooner or later when the development of heat would be most seriously promoted by ventilation, some time before actual ignition demanded the total exclusion of fresh air.

The evidence which has been submitted to the Committee on the subject of the ignition of coal cargoes bears out generally the conclusion to which the above considerations lead, namely, that it is inadvisable to attempt *through ventilation* of cargoes in coal-laden ships.

(Signed) F. A. ABEL.
JOHN PERCY.

APPENDIX TO REPORT

OF THE

ROYAL COMMISSIONERS

APPOINTED TO INQUIRE INTO THE

SPONTANEOUS COMBUSTION OF COAL IN SHIPS.

APPENDIX I.

Correspondence between Board of Trade, Lloyd's, and London Salvage Association.

Board of Trade to Salvage Association and Lloyd's.

Board of Trade, Whitehall Gardens,
April 22nd, 1874.

Sir,

I am directed by the Board of Trade to transmit to you for the information of your Association the accompanying copy of a statement of inquiries, held under the Merchant Shipping Act, into casualties caused by explosion or fire to coal-laden vessels in 1873.

The result of these inquiries is always the same, viz., the officers are exonerated, the court recommends better ventilation; and as the Board of Trade have no reason to believe that the recommendations of the courts have any effect in inducing owners to adopt a better system of ventilation, or render underwriters unwilling to insure vessels of this description, they have decided not to order inquiries in such cases in future.

I am, &c.
(Signed) Thomas Gray.

J. A. W. Harper, Esq.,
Salvage Association.

Inquiries held in the year 1873 into Casualties occurring to Vessels through Combustion of Cargo (Coals), with Suggestions of Courts.

"Zeno," steamship.	Lost in the Bay of Biscay, on the 13th May, through explosion of coal gas.	Inquiry held at Hull 11th June; master acquitted; Court suggested the adoption of stringent measures for proper ventilation of coal-laden ships.
"Berwick," steamship.	Explosion of coal gas on the 9th of May, off the Dudgeon.	Inquiry held at Greenwich on the 26th September; master exonerated; means recommended for ventilating holds of coal-laden vessels.
"Herbert Graham," barque.	Destroyed by fire off Magellan Straits. Spontaneous combustion of cargo of coals.	Inquiry held at Newport (Mon.); master exonerated; means of ventilation suggested.
"Minnie Graham," barque.	Destroyed by fire in the South Pacific, through combustion of cargo of coals.	Inquiry held at Newport; master exonerated; means of ventilation suggested.

A similar letter was addressed by the Board of Trade to the Secretary of Lloyds'.

Salvage Association to Board of Trade.

16, Cornhill,
April 23rd, 1874.

Sir,

I beg to acknowledge the receipt of your letter of the 22nd instant, in which you desire me to inform the Committee that the result of inquiries into casualties caused by explosion or fire in coal-laden vessels held by the Board of Trade is invariably the same, viz., that the officers of the ships are exonerated, that the Court recommends better ventilation; and as the Board of Trade have no reason to believe that the recommendations of the Courts have any effect in inducing owners to adopt a better system of ventilation, or render underwriters unwilling to insure vessels of this description, the Board of Trade have decided not to order inquiries in such cases in future.

The Committee will, no doubt, order me to circulate notice of the resolution of the Board of Trade and the reasons of it, as widely as possible. But, before any steps are taken with that object, will you allow me to ask you if the matter will not admit of a representation of the views of the Board of Trade, something as follow:

(I.) That, as the Courts appointed by the Board of Trade and their assessors acquit the officers of the ships of all blame for explosions, with which the officers have nothing to do, but abstain from finding that the vessels wherein such explosions occur through the absence of proper ventilation are unseaworthy, the Board of Trade have come to a resolution to hold no more such inquiries.

(II.) That they are confirmed in this resolution not to hold inquiries because the owners of these ships are determined that their ships shall continue to go to sea in the unseaworthy condition, which the Board of Trade inquiries apparently ought to have found them to be in.

(III.) Because underwriters, who, at the time when risks are taken on these ships are altogether without means of ascertaining whether or not the ships are unseaworthy in the particular matter of due ventilation, continue to take risks.

I am, &c.
(Signed) J. A. W. Harper,
Secretary.

The Assistant Secretary,
Marine Department,
Board of Trade.

Board of Trade to Lloyd's.

Board of Trade, Whitehall Gardens,
September 29th, 1874.

Sir,

I am directed by the Board of Trade to request you to be so good as to move the Committee of Lloyd's to cause a table to be prepared for the Board of Trade of such coal-laden vessels as have been reported to them as lost or damaged through the spontaneous combustion of their cargo during the twelve months ending 30th June last.

I am to request that as far as possible the table should state the name, port, and tonnage of each vessel, her voyage, and whether steam or sailing, the date, place, and result of explosion, the number of lives lost, and whether the cargo was ventilated or not.

I am, &c.
(Signed) HENRY G. CALCRAFT.

The Secretary, Lloyd's.

LLOYD'S to BOARD OF TRADE.

Lloyd's, E.C., October 14th, 1874.

SIR,

I AM directed by the Committee of Lloyd's in reply to your letter of the 29th September to forward to you the enclosed two copies of the return of casualties to coal-laden vessels by fire, prepared by the Committee so far as it lies within their power to ascertain the losses or damages requested in your communication.*

I am, &c.
(Signed) HENRY M. HOZIER,
Secretary.

The Assistant Secretary,
Marine Department, Board of Trade.

LLOYD'S to BOARD OF TRADE.

Lloyd's, November 5th, 1874.

SIR,

WITH reference to my letter of the 14th October enclosing a return of coal-laden vessels reported in Lloyd's List as lost or damaged through fire during the twelve months ending 30th June 1874, I beg to enclose you a supplementary return showing the coal-laden vessels reported in Lloyd's List as lost or damaged through fire from 1st July to 31st October 1874.

I am, &c.
(Signed) HENRY M. HOZIER,
Secretary.

The Assistant Secretary,
Marine Department, Board of Trade, S.W.

P.S.—I also enclose a list of coal-laden vessels posted as missing from 1st July to 31st October 1874.

LLOYD'S to BOARD OF TRADE.

Lloyd's, November 7th, 1874.

SIR,

I AM directed by the Committee of Lloyd's to inform you that the Committee have learned with regret that the Board of Trade has abandoned holding inquiries in the case of fire to coal-laden ships. By the return of coal-laden ships to which casualties are reported to have occurred according to Lloyd's List that I sent to you in my letter of yesterday's date, you will perceive that of late there appear to have been a great number of such casualties, and I am directed to draw your attention to this fact with the hope that you may be able to move the President of the Board of Trade to allow some inquiry to be made into the circumstances connected with the casualties by fire to coal-laden ships.

I am, &c.
(Signed) HENRY M. HOZIER,
Secretary.

The Assistant Secretary,
Marine Department, Board of Trade.

BOARD of TRADE to LLOYD'S.

Board of Trade, Whitehall Gardens,
December 1st, 1874.

SIR,

WITH reference to your letter of the 7th instant, calling attention to the necessity for making inquiry into the circumstances connected with the casualties by fire to coal-laden ships, I am directed by the Board of Trade to state that in the year 1873 official inquiries were held into the cases of the steamers "Zeno" and "Berwick," and the barques "Herbert Graham" and "Minnie Graham" which had been lost through combustion of the cargo of coals.

In each of these cases the master was acquitted, and the Court suggested that means should be adopted for the proper ventilation of coal-laden vessels.

Looking therefore to the uniform result of the inquiries in these cases, the Board of Trade, before resuming them, would be glad to be informed what is the particular advantage which the Committee think is to be derived from them.

I am, &c.
(Signed) THOMAS GRAY.

The Secretary, Lloyd's.

LLOYD'S to BOARD of TRADE.

Lloyd's,
December 3rd, 1874.

SIR,

I AM directed by the Committee of Lloyd's to acknowledge the receipt of your letter of the 1st December, and in reply to inform you that several causes of the frequent occurrence of fires of late in coal-laden ships have been suggested, such as the excess of ventilation, the short time that is allowed between the extraction of the coal from the pit, and its stowage on board ship, the increasing inferiority of coal, and consequent more frequent prevalence of iron pyrites, and that all these and other causes have been supposed to lead to the great risk of loss of life which is involved in the combustion or abandonment of coal-laden vessels. Under these circumstances it appears to the Committee that the object of the inquiry should be to illustrate facts, and to publish them for the information of the general public, with a view to the prevention of the great risk of loss of life which now appears to be involved in the coal trade, and which, according to the tables which I lately forwarded for your perusal, appears to be seriously on the increase.

I am, &c.
(Signed) HENRY M. HOZIER,
Secretary.

The Assistant-Secretary,
Marine Department, Board of Trade, S.W.

SALVAGE ASSOCIATION to BOARD of TRADE.

16, Cornhill, E.C.
December 21st, 1874.

SIR,

ON Tuesday last I laid before the Committee of this Association a letter addressed to the Committee by Sir John Pirie & Co., extensive coal shippers on the subject of coal combustion in ships.

The Committee consider that letter and the whole subject so important that they have desired me to transmit the letter to you, and to express their hope that the suggestions of Sir John Pirie & Co. will receive the very careful attention of Her Majesty's Government.

The Committee are sensible that the subject is one of singular difficulty and extreme obscurity; but a commission of inquiry, composed of scientific and practical men, might possibly discover the causes of active combustion of coal in ships, and so arrive at some practical remedy.

I am, &c.
(Signed) J. A. W. HARPER,
Secretary.

The Assistant Secretary,
Marine Department, Board of Trade.

London,
December 11th, 1874.

GENTLEMEN,

BEING largely interested in the trade, we beg to call your attention to the unusual number of instances lately reported (as per list herewith) of spontaneous combustion of coal laden on board vessels on their way to distant ports.

It is of the greatest importance to all concerned that—

1. The cause of such ignitions shall be investigated.
2. The best means be ascertained for preventing them, when possible, by ventilation or otherwise.
3. Steps be taken to discover the best mode of extinguishing fire when it does occur on board ship.

We take the liberty, therefore, of proposing that the Board of Trade be requested by you to undertake such an investigation, appointing qualified scientific experts to carry out a thorough inquiry.

The present plan of using water or scuttling ships (when practicable) appears to us a most wanton and destructive mode of proceeding, and surely some apparatus may be applied so as to extinguish fire by carbonic acid gas, where the hatches can be battened down.

We are, &c.
(Signed) JNO. PIRIE & Co.

The Salvage Association,
16, Cornhill, E.C.

---

* The Returns enclosed in this and the subsequent letter will be found in an extended form, Appendix V., page 101.

Board of Trade to Secretary, Lloyd's.

Board of Trade, Whitehall Gardens,
Sir, December 23rd, 1874.

I am directed by the Board of Trade to acknowledge the receipt of your letter of the 3rd instant, in which you state that various causes have been suggested to account for the frequent fires on board coal-laden vessels, and that the Committee of Lloyd's think that the object of inquiries to be in future held by order of the Board of Trade should be to illustrate facts, and to publish them for the information of the general public, with a view to the prevention of the great risk of loss of life which now appears to be involved in the coal trade.

In reply I am to request that you will state to the Committee of Lloyd's that the Board of Trade have made many inquiries into cases of fire and explosion on board coal-laden vessels, and these inquiries have shown that the various causes enumerated in your letter are fruitful of great risk of loss of life on board coal-laden vessels. Copies of the reports of the three last inquiries are enclosed.

What remains to be done is to take warning by the facts proved at these inquiries, and to take such steps as may render coal-laden ships safe by better ventilation, by providing means for stifling flames, and by caution as to the description of coals shipped and their condition when shipped, and this involves primarily the interests and responsibility of owners and underwriters.

Some serious steps should be taken by those who own, manage, and insure these ships and their cargoes, and what the Board can properly do to assist such endeavours shall not be left undone.

They, however, are unable to see any use in holding inquiries which seem to lead to no practical result, and they rather wait to see that their report should receive some consideration and attention than propose to themselves a fruitless continuance of disregarded information.

The Board of Trade, however, will not fail to insure full investigation of any special cases brought to their notice likely to bring out any further facts.

I am to add that the Board of Trade learn that the Board of Underwriters in Boston have had their attention directed to the subject, and intend to frame rules showing under what conditions they are prepared for the future to undertake risks on coal-laden vessels.

I am, &c.
(Signed) Thomas Gray.

The Secretary, Lloyd's.

Board of Trade to Salvage Association.

Board of Trade, Whitehall Gardens,
Sir, December 31st, 1874.

I am directed by the Board of Trade to acknowledge the receipt of your letter of the 21st instant and its inclosure from Sir John Pirie & Co., suggesting, that a commission of inquiry should be instituted into the causes of spontaneous combustion on board coal-laden ships.

With reference thereto I am to inclose a copy of a recent letter (23rd December 1874—M. 16285) from this Board to the Committee for managing the affairs of Lloyd's on the same subject.

The Board of Trade will be glad to hear what action has been taken by owners and underwriters in consequence of the numerous reports after the official inquiries already instituted by this Board, what steps, if any, have been taken by shipowners, shippers, and underwriters themselves to ascertain the causes of explosions on board coal-laden ships, or to ensure the proper stowing and ventilating of coal cargoes on board ship, and, further, whether there is any guarantee that if the Board of Trade takes any steps in the direction indicated in your letter either by re-opening inquiries in the case of casualties to coal-laden ships, or otherwise, the result will receive attention or consideration on the part of underwriters, shippers, and shipowners.

I am, &c.
(Signed) Thomas Gray.

J. A. W. Harper, Esq.

Salvage Association to Board of Trade.

Coal-laden Ships.

16, Cornhill, E.C.
Sir, January 1st, 1875.

I am desired by the Committee of this Association to acknowledge with their thanks receipt of your letter of December 31st, 1874, enclosing a copy of a letter from you to the Committee of Lloyd's dated 23rd December 1874, M. 16285.

In reply to your letter to this Committee, the Committee consider that there is in their letter on the subject and in the accompanying letter from Messrs. John Pirie & Co., extensive coal shippers, some guarantee that if the Board of Trade should think proper to take any steps in the direction indicated in a letter of the Committee, that is, in the direction of a combined, scientific and practical, inquiry, the result of that inquiry will receive attention and consideration on the part of underwriters, shippers and shipowners.

With respect to your letter to Lloyd's Committee, they desire me to observe that the Committee were not aware that any inquiries, that is inquiries of the nature suggested by this Committee, viz., by scientific and practical men combined directed especially to the subject of the real causes of combustion of coals in ships, and possibly the means of avoiding them, had ever, up to the date of their letter, been held.

The Committee need not point out to you that an ordinary inquiry, conducted perhaps by a justice of the peace and two assessors, whose principal, if not exclusive function, and principal if not exclusive qualification for the office, are their knowledge of ships and navigation, is not an inquiry calculated to elucidate a subject so difficult and so obscure in itself, and rendered further obscure by the great conflict of opinion.

The Committee presume that these are not the inquiries which you allude to as having led to no practical result.

The Committee are afraid that the facts which you mention as having been proved at such inquiries are generally considered as only discussed, and the real facts remain too uncertain for it to be possible that the Committee should hope they will constitute the warning you desire.

If an investigation were held such as the Committee venture to suggest, one by men of high scientific attainments, and especially scientific acquaintance with coal in its nature and in all its applications of whom the name of more than one will immediately suggest itself to you, combined with persons practically acquainted with coals in the pit and in the ship's hold, the result might be to fix with a certainty, absolute or qualified, what the causes of this dangerous combustion of coals in ships are, and then this great advantage would be gained that the responsibilities would be fixed upon the proper person, and the clear knowledge of those responsibilities would be likely to operate to cure the mischief.

With respect to the projected combination of underwriters in Boston, to model their conditions of insurance to the dangers of combustion, the Committee beg to observe that underwriters are neither coal owners nor shipowners, and are very likely to be wholly unversed in subjects such as that of the combustion of coals, and that it is not improbable that the underwriters in Boston may be found to jump at conclusions which a more thorough knowledge of the subject might discover to be entirely a mistake. And on the whole subject of the intervention of underwriters, the Committee beg to point out that such a remedy is very much too circuitous, indirect, and uncertain to be worth considering on such a critical question as the combustion of coal in ships; and further that a combination of the comparatively few underwriting companies existing in Boston is probably an easy thing. In the underwriting community of London and especially Liverpool, a very difficult, if not an utterly impracticable one.

And as to merchants and shipowners providing a remedy the Committee beg to point out again that at present the facts are not ascertained with sufficient certainty and with sufficient authority to justify any expectation of an effectual remedy in those quarters.

I am, &c.
(Signed) J. A. W. Harper,
Secretary.

The Assistant Secretary,
Marine Department,
Board of Trade.

Board of Trade to Secretary Lloyd's.

Casualties.

Board of Trade, Whitehall Gardens,
Sir, January 14th, 1875.

With reference to previous correspondence upon the subject of inquiries into cases of casualty by fire to coal-laden vessels, I am directed by the Board of Trade to state that the Salvage Association, who have also communicated with this Board upon the subject, have suggested that inquiries should be held into such cases by scientific and practical men combined, and directed especially to the subject of the real causes of combustion of coals in shipping, and possibly the means of avoiding them.

This suggests the appointment of a Scientific Commission, and the Board of Trade would be glad to learn whether this arrangement would meet the views of your Committee.

I am, &c.
(Signed) HENRY G. CALCRAFT.
The Secretary, Lloyd's.

LLOYD'S to BOARD OF TRADE.

SIR, Lloyd's, January 20th, 1875.

I AM directed by the Committee of Lloyd's to acknowledge the receipt of your letter of the 14th January, and to inform you that the Committee consider that an inquiry should be held into cases of casualty by fire to coal-laden vessels by scientific and practical men combined.

I am, &c.
(Signed) HENRY M. HOZIER,
Secretary.

APPENDIX II.

STATUTORY INQUIRIES held by BOARD OF TRADE, and Reports of other Cases received from that Department.

REPORTS of STATUTORY INQUIRIES held under the BOARD OF TRADE into cases of SPONTANEOUS COMBUSTION in COAL-LADEN VESSELS, from 1868 to 1874, inclusive.

"CATTOFIELD" Barque, of Aberdeen, of 450 tons register.

Port Elizabeth,
17th September 1868.

Inquiry into the circumstances connected wtth the loss of the barque "Cattofield," destroyed by fire near the island of Tristan d'Acunha, and abandoned on the 25th August 1868.

Appeared WILLIAM ROBERTSON, who, being duly sworn, deposes:—

I was chief officer of the barque "Cattofield," bound from Leith to Penang, laden with coals. We sailed from Leith on the 22nd June last. Everything went on right until the 24th August, when just after dinner we observed smoke coming out of the after cabin, which I reported to the captain, who said he could hardly believe such, and that I must go and examine. I did so, and found the smoke ascending through the after hatch. I took the hatch off, and found the coals very heated. I reported such to the captain, who examined it himself. The captain held a consultation as to what was best to be done, and all were of opinion there was no immediate danger, and so we secured all the hatches and bore away for the nearest land, which was Tristan d'Acunha. By 4 or 5 o'clock that same night the smoke increased so much as to prevent the men going down the forecastle. We made preparations to leave the ship in the event of the fire breaking out before morning. Early the next morning an explosion took place, blowing off the fore hatches, previous to which the decks had become so hot as to melt the pitch. About two hours afterwards another explosion took place, blowing off the lazarette hatches. In the cabin the smoke now became so dense that we were unable to go below. The vessel was still sailing towards the island, but no land visible from the masthead. We then put some clothing in the longboat and some bread and water, ready to leave at a moment's notice. We did not try to extinguish the fire by pouring water down, because the smoke was issuing so dense that we could not reach the hatches. At 10 a.m. that morning, the 25th, we sighted a vessel and made signals of distress and steered towards her, and she bore down to us and lowered a boat and sent us assistance. We put some more clothing in that boat, lowered our own, and some of the crew left the ship. The captain, the carpenter, myself, and one or two others remained on board our vessel; but the heat and smoke became so bad that we were compelled to abandon the vessel, and just as we were leaving another explosion took place, blowing off the main hatches, the captain being the last man to leave the ship. It was the "Glenlyon," bound to Bombay, that rendered us assistance. The carpenter scuttled the vessel before leaving her. We all went on board the "Glenlyon" and sailed her course, and on the 10th we were put on board the barque "Aletheia" off Cape St. Francis, and landed in Algoa Bay on the 13th instant. The vessel was still visible when we abandoned her, but dense smoke issuing from all parts. Our hatches were properly battened down fore and aft. I considered the fire had gained too much hold of the cargo when we first discovered it to enable us to extinguish it by pouring water on it. The cargo seemed to be generally on fire. The ship was not supplied with a fire engine. I was not present when the cargo was shipped. The ship had not strained at all. The object of scuttling the ship was to prevent collisions with other vessels. She was scuttled from the outside.

Cross-examined.

I first discovered the smoke issuing from the after cabin, and the fore hatch blew off first. I thought the whole cargo was on fire and so general that we did not know where to commence throwing water down. No one could have worked in the hold, from the dense heat, smoke, and sulphur that arose. We battened the hatches down with a view of smothering the fire by preventing access of the air. I should think we were 250 miles from land. I have never heard of coal fires being extinguished. We found it impossible to remain any longer on board. We transferred some of the clothing we had placed in our longboat to that of the "Glenlyon."

WILLIAM ROBERTSON,
Chief Officer.

Before us, the 18th September 1868,
JOHN CAMPBELL, R.M.,
F. S. READ, Assessor.

HENRY JOHN BASTARD, duly sworn, deposes:

I was second officer on board the barque "Cattofield," and remember the chief officer reporting smoke was issuing from the after cabin. I went with him to examine it, when we found smoke coming up the main and after hatches. We took the main hatch off, examined the coals, which we found very hot, and smoke coming up the ventilators through the main hatchway. We thereupon battened the hatches down fore and aft, and steered for the island Tristan d'Acunha. About 8 o'clock that same night the crew came aft and reported the smoke to be so dense that they could not stop in the forecastle. We got the longboat ready for launching and put some water and provisions in it in case the fire should break out and be compelled to abandon the vessel. An explosion took place the following morning, blowing off the fore hatches. The decks had become very hot. Some time after another explosion took place, blowing off the lazarette hatches in the cabin. The smoke increased, but no flames issued. We sighted a sail, which bore down to us and sent us assistance. The smoke and heat had increased so much that we could remain no longer on board, and we all left the ship and went on board the other vessel, being the "Glenlyon." Before leaving our vessel the carpenter scuttled her. An explosion blew off the main hatch just as we were leaving her. On first discovering the fire we had no hopes of extinguishing it. I saw the cargo shipped. The coals were perfectly dry, the hatches were properly battened down, and the ship was tight. From what I could judge the fire seemed to be general.

HENRY JOHN BASTARD.

Before us, this 18th September 1868,
JOHN CAMPBELL, R.M.,
F. S. READ, Assessor.

JOHN MASSON, duly sworn, deposes:

I was carpenter of the barque "Cattofield," and remembered when the vessel was first discovered on fire, on the 24th August. I examined the coals, and found them very heated; smoke was issuing from them. We battened down the hatches. The smoke increased to such an extent that the men could not remain in the forecastle. The following morning, between 5 and 6 o'clock, an explosion took place, blowing off the fore hatch. Some time after another took place, blowing off the lazarette hatches. The smoke and heat had so much increased that we could not go below. During the day we sighted a vessel, and sent us assistance on board. The smoke had become so dense and the heat so great that we could no longer remain on board, and we abandoned the vessel and went on board the other, which proved to be the "Glenlyon." Just as we were leaving the ship another explosion took place, blowing off the main hatch. After we got into the boat I scuttled the vessel by cutting a hole with an adze at midships, just above the copper line. We then sailed in the "Glenlyon." I think it was then about 3 o'clock in the afternoon. I saw the vessel about 5 o'clock. There was smoke issuing from all parts, but no flames were visible. The ship made no water; she was quite tight. I did not see the cargo shipped.

JOHN MASSON,
Carpenter.

Before us, this 18th September 1868,
JOHN CAMPBELL, R.M.,
F. S. READ, Assessor.

Statement of SAMUEL E. JANE, late master of the barque "Cattofield," of 450 tons, burnt at sea.

On the 24th June 1868 I sailed in command of the barque "Cattofield," of Aberdeen, from Leith, laden with a cargo of coals at that port, and bound for Penang. On the following day, 25th June, anchored in Aberdeen Bay to land a sick man. At 9 p.m. of same day got under weigh and proceeded on the voyage.

Nothing of import occurred until the 24th August, when the ship had reached the latitude of 34° 24′ S., longitude 15° 40′ W.

About 1 p.m. on that day smoke was observed issuing from the after cabins. I immediately examined the hold, and found smoke ascending up through the coals and ventilators, and the heat very great a little below the surface. The coals had evidently ignited. I then had all the hatches closed down to prevent flame from bursting out, and bore away for the islands of Tristan d'Acunha, distant about 250 miles in S.S.E. direction.

At 9 p.m. the smoke became so dense it was impossible to remain below, the fire increasing rapidly and smoke issuing from every aperture. Fearing it would be impossible to reach the islands, at midnight got the boats ready for launching, placing a little provisions and water in each, in order to leave the ship at any moment, should the flames break out.

At daylight on the 25th, nothing was visible from the mastheads; we continued running towards the islands, the wind blowing strong from the N.E. with a rough sea. About this time an explosion took place, blowing off the forward hatch.

About 9 a.m. a sail was descried ahead from the main topgallant yard. I immediately steered for her with distress signals flying, and about noon we were near enough to exchange signals. She proved to be the ship "Glenlyon," of Quebec, from Liverpool, bound to Bombay, commanded by Captain McIntyre, who on learning our condition at once hove to, and sent a boat alongside to render us any assistance needed.

The wind freshening and the sea rising, no time was to be lost in leaving the burning ship, it being now utterly impossible to get below.

We then launched the boats, and putting what clothing could be got into them, abandoned the ill-fated "Cattofield" about 3 p.m. on the 25th August last, scuttling her before doing so.

Previously to the last boat leaving the ship another explosion took place, blowing off the main hatches. The smoke rushed up in clouds. I immediately jumped into the boat and shoved off. We were very kindly received by Captain McIntyre, of the "Glenlyon," and every attention was paid to our comfort while on board his ship. When the "Cattofield" was last seen, smoke was pouring in volumes from every hatchway and skylights, and she could not possibly last for many hours.

And I must here express my gratitude to Captain McIntyre, who, under Providence, was the means of rescuing us from the horrors of a burning ship.

We remained on board the "Glenlyon" until the 10th September, when a part of the crew were transferred to the "Aletheia," bound for this port; the weather becoming bad, the remainder of the crew remained on board the "Glenlyon" until the following morning, when they were all transferred to the "Aletheia," and were safely landed here on Monday the 14th instant, all in good health, viz., myself and 15 men.

I cannot let the opportunity pass without thanking Captain Daniels, of the "Aletheia," on behalf of myself and crew, for the promptness with which he consented to receive us on board his ship (already full with passengers), and the trouble taken by him and uniform kindness evinced towards us while on board.

S. E. JANE,
Port Elizabeth, late Master of the "Cattofield."
17th September 1868.

Judgment of the Court.

The Court is of opinion that the abandonment of the barque "Cattofield" was not caused by the wrongful act or default of the captain, but the cause of her loss was spontaneous ignition of her cargo of coals.

JOHN CAMPBELL, Resident Magistrate
F. S. READ, Assessor.

"PERSIA,"* of Glasgow, a wooden ship of 1,289 tons register, four years old, classed A 1 for seven years.

The Mauritius Marine Board met on Friday, 27th November 1868, for the purpose of inquiring into the loss by fire of the ship "Persia," of the burthen of 1,289 tons, James Clark, master, which took place in lat. 40 South, long. 21 East, or thereabouts, on the 2nd instant.

Members of the Board present:

D. WALES, Harbour Master and President.
A. W. BARCLAY, Surveyor and Merchant.
J. COWIN, Surveyor.

Appeared before the Board for examination, and were duly sworn:

James Clark, master; Peter Hutchinson, mate; Hugh Conville, 2nd mate; together with several of the crew of the late ship "Persia."

The master and the two mates were examined on oath; their evidence was clear and precise. It was not considered necessary to call in any of the crew.

It appeared from the evidence, and also from the log book, that the "Persia" sailed from Greenock on the 31st August 1868, laden with coals and bound to Bombay; she was tight and staunch when she left, and continued so to the time of her loss. The voyage was prosecuted successfully till the 1st of November, when gas and smoke were observed rising from the coals about the midship part of the vessel, and on examination it was evident from the heated temperature that combustion was going on. This was met and combated by every available means; water was freely poured over the part that appeared most heated, the deck above being scuttled for that purpose; the force pump was worked by a portion of the crew and directed to the same spot. The water in the well soon increased to 3 feet, and the vessel's pumps were set on and the water as it rose conducted on the burning coal. Coals were dug out and thrown overboard in the hope of getting at the real seat of the fire, and a party of men remained at that work till driven on deck by the rapidly increasing volume of gas and smoke. The "Black Watch" hove in sight at this critical time; it was now evening; she laid by the "Persia" during the night, and on the morning of the 2nd November, the captain, officers, and crew abandoned the ill-fated vessel, from every hatchway of which columns of dark, black smoke, with occasional flashes of flame, were issuing. Mr. Kerruish, the master of the "Black Watch," fully confirmed this part of the statement.

There was in fact so little time to spare that hardly any of the effects of the crew were brought away, and the master and mates lost everything, certificates included. There is no doubt in the opinion of the Board that every possible exertion was made to save vessel and cargo.

In reference to this loss the board would remark that in their opinion the burning of coal-laden vessels demands the serious investigation of scientific men. These fearful accidents are increasing in frequency, and spontaneous combustion is hardly a satisfactory conclusion to arrive at. Why is there spontaneous combustion? Why does one ship burn from that cause, and dozens of others laden from the same pit, at nearly the same time, arrive safely at their destination? Is ventilation of the coal advisable or dangerous? Ought hatches to be kept on or off? Could not inflammable gases be pumped out of a ship's hold? Is there not a method of creating gases in an inexpensive manner on board ship that would smother and extinguish any amount of fire in a vessel's hold? Such measures are spoken of commonly enough but are apparently never carried into practice. Three large coal-laden vessels, the "Pernix," "Volante," and the "Persia" have been burnt at sea, and their crews arrived in this colony during the last year. What destruction of property? What risk to life? What privation and suffering do these burnings entail? At this moment there is a valuable vessel in this port, coal-laden, which narrowly escaped the same fate as the "Persia," the coals having been smouldering many days before they could be extinguished.

---

* For the correspondence, arising out of this case, between the Board of Trade and the Local Marine Boards in the United Kingdom, *see* page 25.

The Board submit these remarks for consideration, and hope that the very important subject they refer to may be thought worthy the attention of competent persons. Certainly any one who will point out the way in which coals may be conveyed to distant ports without greater risk than the generality of cargoes will have deserved well of owners, sailors, underwriters, and last not least, of humanity.

D. Wales,
Harbour Master, President.
A. W. Barclay,
Marine Surveyor.
John Cowin,
Marine Surveyor.

"L'AGOUHANNA," of Glasgow, a Quebec-built ship of 1,103 tons register.

Bombay Fort Police Court,
Tuesday, 16th February, 1869.

Pursuant to the Government notification, Marine Department, dated the 10th instant, appointing John Connon, Esquire, Acting Chief Magistrate of Police, and Lieutenant G. O'Brien Carew, late Indian Navy, to conduct an investigation into the circumstances connected with the loss by fire of the ship "L'Agouhanna" on Tuesday, the 2nd instant, about 30 miles west of Hurnee, and 100 miles south-west of Bombay, the Court assemble this day at half-past 2 o'clock p.m. for the purpose stated.

Mr. Hearn, solicitor to Government, appears to watch the case on behalf of Government.

William Kennedy sworn; examined by Mr. Hearn.

I was captain of the ship "L'Agouhanna." I hold a master's certificate from the Board of Trade, No. 28,697, dated 14 July 1863.

She was Quebec-built and 1,103 tons burthen. We were bound from Liverpool for Bombay with a cargo of coal. The coal was shipped in Birkenhead Docks. It was called West Hartley coal or North Wales coal. It came by railway as far as I could tell direct from the pits. We came out of the docks on the 30th of September last and started direct on the voyage. Everything went right up to the 4th of February. On the 2nd of this month my second officer who has been acting for the chief officer, Mr. McKee, came and reported to me, about 7 o'clock in the evening, that there was a smell of something like naphtha or coal tar, and that the paint was a little stained just by the forehatch. I went to investigate this, but I could find no greater heat than I had noticed during the rest of the voyage. There was a little steam, but nothing more than I noticed three days after we left Liverpool. I sent the second officer down below the same evening. He reported that there was no more heat below than there was on the forehatch, next morning a little after 4 o'clock, when I went on deck, the boatswain came and said he thought there was fire in the ship. I sent for the carpenter and sent him below. He came up in about ten minutes and reported the ship was on fire, and that the smoke was coming up strong by the stanchions, and said there was every appearance of fire amongst the coal. I immediately ordered the force pump to be got out and applied water to every available place in the hold. We continued throwing water with buckets as well as the pumps till 8 p.m. The smoke was at that time so strong that the men could not stop below for more than a few minutes at a time. The smoke was coming up through all the hatches and through the ventilators besides; of these we had one upright down each hatch. There was an upright ventilator connected with others that went fore and aft both above and below the beam. At this time we were in 30 fathoms water and about 30 miles from the land, as far as I can judge south-west of Hurnee. The wind was about north-north-west. The ship was under sail, making the best we could for the land, and so we continued until 4 o'clock next morning, the weather being at that time very fine. At 4 o'clock on Wednesday morning, 3rd February, I called the hands aft and told them my opinion about the ship being on fire, and ordered the boats to be got ready and provisioned in order to be prepared for the worst. That was all done by daylight; water was still being thrown below by the hose. The men had been obliged to leave the forecastle at 3 o'clock. In the course of the night I tacked the ship to the westward fearing to get too near the land; at 3 o'clock I tacked again to the eastward to get nearer the land. About 7 or 8 o'clock, as near as I can remember, the smoke became so strong we could not stop on deck and we had to take to the boats and about a quarter of an hour after that we saw the flames coming up through the after hatch, the cabin skylight, and the stern windows. About an hour after this, when we were pulling for the land, the main and mizzen masts fell, and between 11 and 12 the foremast fell. I reached land with my boat about 10 at night. One or two of the other boats had reached from 4 to 7. We made out the glare of the burning ship until about 12, when it disappeared.

All the crew came safe to land. I saved my chronometer, part of my clothing, and sextant. I lost all my charts and nautical books with the rest of my library.

This is the ship's third voyage to Bombay with coal. I never experienced an alarm of fire before. I noticed no particular difference between the coal on this occasion; in fact there was less steam on this occasion from the coal than there was from the coal on the first voyage.

I can only attribute the fire to some inflammable quality in the coal, and I think the fire first took place in the bottom of the ship. According to my experience coal is always shipped or stated to be shipped direct from the pits, and according to my experience coal ships now-a-days catch fire more frequently that they formerly used to do.

By the Court:

We were about nine days in loading, no fresh water got into the cargo then, nor afterwards. It was showery when we were loading, but we stopped loading during the showers. It was about eight and twenty hours when we took to the boats after the fire was discovered. I always thought we should be able to drown out the fire till we were compelled to take to the boats. We could not get the ship nearer the land because there was no wind from midnight of Tuesday until the time we left the ship with the boats. I cannot say whether the coal on this occasion was from the same pit as the coal we carried on previous occasions.

In this ship or any other ship I know of laden with coals, if a fire were to break out in the bottom of the hold, there are no means of immediately finding it out.

William Kennedy.

Taken on oath before us,
John Connon,
Acting Chief Magistrate of Police,
G. O'B. Carew,
Lieutenant, late Indian Navy.

Robert McKee sworn; examined by Mr. Hearn.

I was second officer of the ship "L'Agouhanna." I have been doing duty as chief officer for the last two months and half, during the illness of the chief officer. I hold a certificate from the Board of Trade as second officer. I did not the see coal taken on board. I only joined the ship on the 28th September. There was no appearance of fire until the 2nd February, on which day, at 6 o'clock in the evening, I called the captain's attention to a smell. I did not think it was fire; I thought it might be a little extra steam. The captain at once sent the carpenter below and I went down myself. I discovered no extra heat. I first discovered the ship was on fire at 4 o'clock on Tuesday morning, and we continued pumping and throwing water into the hold all that day and night till about half-past 3 o'clock on Wednesday morning. I thought all Tuesday that we should get the fire under. On Tuesday night, between 7 and 8, the smoke became so suffocating that we could not stay below. I went down the main hatch about every ten minutes and shifted the hose on to the hottest place.

The hands were pumping and carrying water in buckets all through the night. They were driven from the forecastle about half-past 3, and we then found it was a hopeless case. The boats were then all got ready, watered and provisioned, and dropped astern, and we were obliged to take to them about 8 o'clock. The wind was about north-north-west on Tuesday night. It was fresh during part of the night. It fell light about 12 o'clock, I reached the shore about half past 6 o'clock on Wednesday night. I could see the glare of the fire at that time. The ship's hands could not have worked harder, and nothing more have been done than was done to put out the fire.

Robert McKee.

Taken on oath before us,
John Connon,
Acting Chief Magistrate of Police,
G. O'B. Carew,
Lieutenant, late Indian Navy.

Adjourned.

Bombay Fort Police Court,
Friday, 19th February 1869.

Mr. Hearn appears to watch the case on behalf of Government.

Alexander Smith sworn; examined by Mr. Hearn.

I am the carpenter of the "L'Agouhanna." This is my third voyage in her. I saw her take in coal at Liverpool. I was by her all the time. It was in the month of September. It was not much wet. There were summer showers. The coals were quite dry when they were shipped. They came by railway. The coal was in good order. In my opinion no water, either salt or fresh, could have got to the coals after they were shipped, from the precautions I took. The ship is very tight; she did not make an inch of water in 24 hours. The first thing that came to my notice on Monday, the 2nd February, was that the paint at the fore hatch was discoloured, but I thought there was nothing unusual in this, and did not think it was necessary to to mention it to the captain. Next morning at 5 a.m., the captain sent me below to see if there was any heat among the coals. I went below, half way between the fore and main hatch by the stanchions. I saw the smoke coming up by the stanchions. I moved a quantity of coal, and noticed the smoke coming up much stronger, and there was a smell like coal-tar or naphtha. This was about the centre of the ship. I tried the same experiment towards the sides and forward, but there was no heat whatever. I went on deck again and told the captain the coal was on fire. He got a force-pump to work at once among the coals. It was a good and powerful pump. The pumping went on from Tuesday morning until we left the ship on Wednesday. The fire got worse, and the men could not stop below. They could only go down for a minute to shift the hose. The fire spread aft first, about 6 o'clock on Tuesday evening. About 5 o'clock on Wednesday morning we found it was a hopeless case. The men worked as hard as they could, and everyone did his best. The captain then gave orders to get the boats ready, and to have them provisioned. About 8 or 9 o'clock we took to the boats. The fire was actually blazing before we left the ship. The weather was fine on Tuesday, with a light breeze, and the ship was going slowly through the water. At midnight it fell calm. I cannot form any opinion as to how long the coal had been on fire. It might have been smouldering for a long time. I was never in a coal ship before, when the coal took fire. I cannot give any opinion as to the origin of the fire.

By the Court:

We had no naphtha or coal-tar on board; we had no cargo except coal.

Alexander Smith.

Taken on oath before us,
John Connon,
Acting Chief Magistrate of Police,
G. O'B. Carew,
Lieutenant, late Indian Navy.

Isaac Newton sworn; examined by Mr. Hearn.

I was boatswain on board the "L'Agouhanna." I saw all the coal shipped at Birkenhead. It was dry weather all the time we were taking in the coal. I noticed nothing unusual about the coal until Monday morning, the 2nd February. I thought there was more smell or dry heat. I had noticed a dry heat for several days, and not so much steam as on former occasions. On Tuesday morning about 4 o'clock I told the captain I thought there was more smoke coming up than there was yesterday. Upon this the captain told me to take the watch below and examine the coal, which I did as far as I could. I found the coals very hot, and a kind of vapoury smoke coming through. I went up and reported this, and the captain ordered the hose to be got out, and we kept playing water on the coals all day and all night. The fire continued to get worse and stronger, notwithstanding that everyone was doing his uttermost to get the fire under. On Wednesday morning the ship was too hot to hold us any longer, and we took to the boats. I reached the shore about sundown. I saw the main and mizzen masts fall soon after we left. I know of nothing inflammable on board except the coal.

Isaac Newton.

Taken on oath before us,
John Connon,
Acting Chief Magistrate of Police,
G. O'B. Carew,
Lieutenant, late Indian Navy.

Decision of the Court.

Bombay Fort Police Court,
Wednesday, 3rd March 1869.

Pursuant to the Government notification, Marine Department, dated the 10th February last, appointing John Connon, Esquire, Acting Chief Magistrate of Police, and Lieutenant G. O'Brien Carew, late Indian Navy, to conduct an investigation into the circumstances connected with the loss by fire of the ship "L'Agouhanna" on Wednesday the 3rd idem, about 30 miles west of Hurnee, and 100 miles south-west of Bombay, the court assembled on the days mentioned in the proceedings for the purpose stated.

From the evidence taken before us with regard to the destruction of the "L'Agouhanna," from Birkenhead, when approaching the port of Bombay, by fire, on the 3rd February last, we have arrived at the conclusion that spontaneous combustion in a cargo of coals was the cause of this accident.

It appears also from the evidence that the weather was showery, while the coals were being taken on board in the latter end of September last, or when they were conveyed from the pits, and this may perhaps have been the primary cause of the coals subsequently taking fire.

The captain in his evidence says all went well till the 1st February; on the next day, however, there was indication of fire among the coals, and the second mate was sent below to examine the state of the cargo. The next morning (3rd February), the boatswain expressed an opinion that there was fire in the ship's hold, and on the carpenter being sent for, he (after 10 minutes examination) reported there was fire among the coals, and at 8 p.m. of the same day the smoke was so strong that the men could not remain below more than a few minutes at a time.

On that day the captain called the crew aft and informed them that it was necessary to be prepared for the worst, and gave orders for the boats to be lowered and provisioned. On the following morning all hope of saving the ship being at an end, the captain and crew left in the ship's boats in good order and discipline, reaching the shore at Hurnee in the course of the same day. The ship seems to have gone down very soon after being thus abandoned.

We are of opinion under these circumstances that the ship should at once have been headed for the shore (at that time 30 miles off), where she might have been bilged without causing her total destruction; water would by that means have been admitted in at the seat of the fire, and with assistance obtained from the shore the bulk of the cargo as well as the ship might have been saved, as the captain believes (and we think correctly) that the seat of the fire was in the lowest portion of the cargo.

We are therefore of opinion that the captain acted injudiciously in standing to the westward, even if he did so for a short time, only with a view to the chance of meeting passing vessels and thus obtaining assistance.

The ship's log shows that fresh and moderate breezes prevailed, and there is no mention of calms during the time alluded to, the wind being north-north-west, and the port of Hurnee bearing about north-east, so that on a taut bowline and flood tide that port could have been made and the distance accomplished in eight hours, supposing the ship not to be making more than four knots an hour.

When the fire had got the upper hand and the captain saw that it was beyond the control of water applied, he should, we think, have adopted a plan universally followed by the chimney sweeps in England, by which (in case of a chimney being on fire) they exclude all air and smother the fire out by its own smoke.

It moreover appears from the evidence that there was an elaborate system of ventilation through the cargo. This ventilation, we are of opinion, should have been closed when it was discovered that the fire could not be controlled, and the excess of smoke mentioned by the captain and others might have smothered the flame, or at least given them ample time to have reached the shore.

In making these remarks with regard to what appear to us to be omissions on the part of the captain of the "L'Agouhanna," we fully recognise that he acted promptly and to the best of his judgment under the circumstances, and that every exertion was most creditably made on the part of both officers and crew, to carry out his instructions; nevertheless we conceive that he was wanting in resource in failing to adopt the precautions afore mentioned, although we are satisfied that according to his own conviction he made every effort to save the ship.

In connexion with this inquiry we would respectfully notice the frequent destruction by fire of coal-laden ships. A great number of such vessels have been destroyed by the coals taking fire within the last year or two.

During the last twelve months five vessels (the names of which are given in the margin) laden with coals have been discovered on fire in the port of Bombay, as reported by the master attendant of this port, and a number of others have been burnt on their outward voyage to India. It is, we would respectfully submit, a matter of great importance that means to detect any tendency to fire on board these ships, and of promptly meeting it when it exists, should be adopted with the least possible delay.

"Bell Isle,"
one year ago.
"H. E. Richardson,"
"Royal Albert,"
"Glenlyon,"
"Hannah Law,"
within the last six months.

In view to the adoption of such measures we offer for the consideration of Government and others interested the following suggestion:—

In the case of all ships laden with coal a cylinder of iron, three inches in diameter perforated its whole length and reaching down to the bottom of the cargo, should be placed in the centre of each hatchway, a rod of wood to fit easy being introduced to prevent the coal dust filling it through the holes while loading; when the loading is completed the wooden rod should be replaced with an inch iron one of the same length; at short intervals of time these should be carefully examined; to render such examination easy an eye should be formed at the head of the iron rod, to which can be attached a whip from aloft, and the rods drawn and examined in a few minutes; even while in the act of withdrawing the hand can examine them, and having done so to within a foot of the end they can be again lowered.

Should the rod be considered not sufficiently sensitive to detect through the cylinder a slight increase of heat, a thermometer lowered by a line could be used, and it should also be used occasionally to ascertain the mean heat; any great increase would give the necessary warning.

In the event of fire the hose of the pumps can be introduced into the cylinders and water thrown to the bottom of the cargo, and disseminated by means of the holes to all parts of it.

With these means there would be little or no danger of fire getting the upper hand, as the only question on the occurrence of fire would be a sufficient supply of water, and with good force pumps that could be easily obtained.

We do not consider that the captain deserves any punishment, beyond the slight censure implied in the foregoing finding; and the officers and crew of the ship seem to have behaved well throughout.

John Connon,
Acting Chief Magistrate of Police.
G. O'B. Carew,
Lieutenant, late Indian Navy.

W. R. S. FitzGerald,
Bombay Fort Police Court,
3rd March 1869.

"COMMODORE PERRY," of Newcastle, wooden vessel of 1,978 tons register, 14 years old, classed at American Lloyds A1½ for 3 years in January 1869.

Bombay Fort Police Court,
Monday, 6th September 1869.

Pursuant to the Government notification, Marine Department, dated the 1st instant, appointing John Connon, Esq., Senior Magistrate of Police, and Lieutenant G. O'Brien Carew, Indian Navy, to conduct an investigation into the circumstances connected with the loss by fire of the ship "Commodore Perry" in the Bombay Harbour on the night of the 28th August last, the court assemble this day at half-past 2 o'clock, for the purpose stated.

Mr. Hearn, solicitor to Government, appears to watch the case on behalf of Government.

Thomas Black sworn; examined by Mr. Hearn.

I was the master of the ship "Commodore Perry." I have received a copy of the report on which this investigation is ordered. The "Commodore Perry" was ship-rigged, and a wooden ship 1,978 tons register; she belonged to Messrs. Thompson and Harper, of Newcastle-on-Tyne. I am not certain, but I think she was 14 years old; she was classed American Lloyds A1⅓ for three years in January last. I was on a voyage from Newcastle to Point de Galle for orders, with a cargo of coals. We had 2,560 tons of coal on board. It was Davidson's West Hartley coal. I saw part of the coal put on board, but not the whole. Part was shipped by wagons and about 250 tons out of lighters, from about 2nd February to 23rd March last. This is the second voyage I have taken her with coals. The coals were loaded dry. The ship had three decks. The lower hold was nearly full, the first deck two thirds, and the next deck a little over one third. The coal was stacked. Between the coal and the decks there was a current of air above and on the sides of the coal. Besides this the coal was ventilated by the fore and after hatches. A ventilator about four feet square ran from the poop down to the lower hold. I left Newcastle on the 8th March and arrived at Galle on the 7th July last; but having to put out again on account of the current, I did not get back again till 23rd of the same month, and left the following day for Bombay. On the 25th August a report was made to me that there was a large quantity of steam in the fore hatchway. I could not make out what it was at first, but on Friday, the 27th, I made out that the ship was on fire. There was a great deal of smoke in the latter part of the afternoon of that day. We made Kennery Light at dusk on Saturday evening the 28th. The pilot came on board about 9 p.m., and shortly afterwards there was an explosion which blew the fore hatches up, killing or suffocating the steward. The ship was immediately anchored. There was no flame visible at this time. The smoke was nearly all coming out of the fore hatch. The cabin was filled with smoke. I got the boats out as speedily as possible, being afraid that the ship might blow up in the main hatchway. After I got the boats out I went on shore for assistance. I first went on board Her Majesty's overland transport "Euphrates." I gave orders to the chief officer what should be done during my absence. I got back to the ship at about a quarter-past 5. She was then on Karanja shoal, she was a little below her loaded mark; tide ebbing at the time. She was burning very much forward at that time. Two water boats at that time were playing on her. They continued playing on her for the most part of that day. I went on shore about 6 o'clock to procure lighters to save the ship's stores. I went back towards the ship at half-past 5 in the afternoon, and found every one had left the ship. I returned to the shore in the Anchor bay. I gave up all idea of getting the fire under. The ship continued to burn from that time till she was consumed. I have been back to her three times. The second time I saw she was burnt down to the level of midships and below the loading mark at either end. I attribute the fire to spontaneous combustion of the coal. I can form no opinion why this cargo of coal caught fire while the other did not. I should have thought the other cargo of coal was more likely to take fire, as I am generally suspicious of Welsh coals. I have had a great deal of experience of coals, and as regards this cargo it was shipped under unusually favourable circumstances. It was fine weather, and the coal was shipped very dry. I produce the certificate I hold from the Board of Trade as Master, dated 4th March 1852, and No. 3,632.

By the Court.

We had rain several times on the voyage. The hatches were ordered to be put on whenever rain came. The ship did not make much water during the voyage; she was usually tight; she made more water just before we reached Bombay in two hours than she had previously done in 12 hours. I attribute this to the burning of the ship. I think the fire must have been in the lower 'tween decks, between the main and fore hatch. I left my ship for the purpose of obtaining assistance. I considered the ship was safe, as she was then at anchor, and therefore left myself in order to obtain assistance as speedily as possible. I have not heard of ventilator tubes being put through the cargo at different times in order to ascertain the heat. I never heard of that system prevailing in the Royal Navy. Some people think ventilators are of no use. I cannot give any opinion on this point myself, not having tried ventilators. I do not think the ship was fully insured. I know nothing about the cargo.

Thomas Black.

Taken on oath before us,
John Connon,
Senior Magistrate of Police.
G. O'B. Carew,
Lieutenant, late Indian Navy.

William Wright Sinclair sworn; examined by Mr. Hearn.

I was chief officer of the "Commodore Perry." I hold a master's certificate from the Board of Trade, and also a master's certificate from the Bombay Government; the Bombay certificate is dated June 1860, and the English certificate, 14th February 1862. The first time we saw any steam coming up was on the 25th August. On that day, as usual, I was up and down the hold two or three times. I did not notice any particular difference in the coals on that day; on the next day they were a little warm towards midships, and I fancy the fire must have broken out rather forward of the main hatch. Smoke was first visible on the 26th. I could not see any particular spot where it was coming from. The coal was quite dry. I saw the best part of the coals laden. They were very dry. The only opinion I can form as to the cause of this fire is that it must have originated from spontaneous combustion.

W. W. Sinclair.

John Connon,
Senior Chief Magistrate of Police.
G. O'B. Carew,
Lieutenant, late Indian Navy.

The other witnesses summoned in this inquiry are asked if they have anything to say to the court with regard to the destruction of the "Commodore Perry" by fire, and they reply that they are unable to say how the fire occurred.

The court adjourn until Monday next, the 13th instant, at half-past 2 p.m., to consider their decision.

John Connon,
Senior Magistrate of Police.
G. O'B. Carew,
late Indian Navy.

Decision of the Court.

Bombay Fort Police Court,
Monday, 13th September 1869.

Pursuant to the Government notification, dated the 1st instant, appointing us to conduct an investigation into the circumstances connected with the loss by fire of the British ship "Commodore Perry" in the Bombay Harbour, on the night of the 28th August last, we beg to report that the court met for this purpose on Monday the 6th instant.

From the evidence before us it appears the—

"Commodore Perry" was a wooden ship, and was 1,978 tons register. She was 14 years old; but the captain, Mr. Black, states she was classed in January last American Lloyd A1½ for three years. She left Newcastle in March last for Point de Galle, and was loaded with 2,560 tons of West Hartley coal.

Nothing particular appears to have occurred during the voyage. The ship arrived at Galle on the 7th July last, but had to put out again an account of the current, and did not get back till the 23rd of the same month. She left on the following day for Bombay. On the 25th a great quantity of steam was observed in the fore-hatchway. The captain states he could not at first make out what it was, but the next day (Friday) he found the ship was on fire. The ship kept on her course, and Kennery Light was made out at dusk on the evening of Saturday the 28th. She was boarded by the pilot at 9 o'clock that night, and shortly afterwards there was an explosion, by which the steward met his death. The ship was immediately anchored, and the master left her in order to obtain assistance from the shore. When he returned next morning about a quarter-past 5 o'clock, he found the ship on Karanja shoal. All efforts to extinguish the fire were unsuccessful, and the ship continued to burn till she was consumed.

We are of opinion, after careful consideration of the evidence brought before us, that spontaneous combustion among the coals was the cause of the loss of the ship.

No precaution was neglected by the captain or officers. The holds were examined, and the hatches on the occurrence of rain were attended to.

The court considers no blame can be attached to the officers or anyone on board. All appear to have behaved well in working their vessel into port, knowing her to be on fire, and liable at any hour to explode or burst into flames, when they would have little or no time to take to the boats.

That all on board were in great danger is sufficiently evident by the fact of explosions having occurred shortly after the vessel was anchored, resulting in the loss of one life, and it is also stated that another man was injured.

The court considers that the captain's certificate should be returned to him, and it is returned accordingly.

John Connon,
Senior Magistrate of Police,
G. O'B. Carew,
Lieutenant, late Indian Navy.

Confirmed,
W. R. S. FitzGerald,
Governor.
Bombay Fort Police Court, 13th September, 1869.

"BEACON LIGHT," of St. John's, New Brunswick, of 916 tons register. She was launched at New Brunswick on the 8th September 1869, and classed in the French Lloyds for seven years.

A Marine Court of Inquiry will assemble at the Police Court, Steamer Point, to-morrow morning, the 26th instant, at 7, to investigate and report on the circumstances attendant upon the burning of the ship "Beacon Light."

President: Lieutenant Prideaux, Assistant Resident.
Member: W. K. Thyne, Esq., Harbour Master, and Conservator of the Port.

Aden Residency, 25th January 1871.

The court having assembled pursuant to orders, proceed to read aloud a report handed in by the master of the "Beacon Light," in presence of the officers and crew of that vessel:—

Report of ship "Beacon Light," 916 tons register, of St. Johns, N.B., Fry, master, from Greenock to Rangoon, coals.

September 1st. We towed from tail of bank off Greenoc to Lamlash, and left there on the 2nd. We had light winds and a tedious passage to the Equator; nothing whatever occurring more than is common in any oversea voyage until November 3rd, when Gustav Stoltenhoff, O.S., fell from the cross-jack yard to the deck and was hurt, but no bones broken. On November 8th, at 5.30 p.m., smoke was seen coming up the fore hatch. Master and first mate went into the hold immediately and saw smoke coming up through the cargo at the afterpart of the deck-house on the port side, not far from wood ventilator that went down into the cargo. Immediately took off main hatches and hove coals overboard, so as to be able to get to play water. The force pump was also at once put to work and continued to play water during the night. The main hatch beams and two beams forward were cleared to our view by coals being discharged. The coals and beams on the beams on the port side from main hatch forward to some distance were hot, and it was here the smoke came from. We played great quantities of water from main and force pumps.

November 10th, 6 p.m. We had strong hopes that we were conquerors, but to our utter astonishment, about 3 a.m., on the 11th, great quantities of smoke came from the port side, not allowing any one to go into the hold. We considered it best to batten down main hatches and cut holes in the deck to admit water from main pumps with a hose. In the afternoon removed the long boat from the foreward house to after beams, some hands employed getting sails ready for boats and others pumping.

6.30 p.m. Crew all on deck, some pumping, others in the act of getting sails and painters ready for boats.

With a loud report like a cannon and a flash like lightning all hatches were blown up, fore and aft, carrying the second mate overboard with main hatches, who was seen no more, as night was coming on and great quantities of smoke coming up fore and main hatches, a heavy sea running at the time. The master ordered the boats to be got out for the preservation of life, as there was no chance of saving the ship. The long boat was got out with much difficulty. In getting out the pinnace she was capsized alongside, and John Tompson, seaman, drowned. Everybody, from master to ordinary seaman, used every effort night and day to save the ship. The ship was being steered S.E. by E. in hopes of getting to Tristan d'Acunha. About 9.30 p.m., as near as we could judge, we parted from the ship. Great quantities of smoke were coming from all her hatches. We steered for Tristan, and on Sunday evening saw the land. On the following morning we were met by the kind settlers of that island who had both bread and milk with them in their boat. They joyfully welcomed us to their homes. We were in the boat three nights and two days, in all 61 hours. The boat is left for the good of the settlement on the island. Lat. 35° 31′ S. long. 18° 31′ W. at noon of November 11th, ship run 52 miles S.E. by E., which made us about 274 miles from Tristan when we left the ship.

We, the undersigned members of the crew, declare this to be a true and faithful report of the said ship and her loss.

Ship "Northfleet," January 24, 1871.

Statement of Edwin Fry, taken upon oath this 26th day of January 1871, which said deponent saith:

The statement presented by me to the court is a true and accurate account of the circumstances attending the burning of the ship "Beacon Light," 916 tons, of New Brunswick (St. John's).

She was launched on the 8th September 1869, at New Brunswick, and was registered in the French Lloyds for seven (7) years. Master's certificate of competency, No. 20,707.

1,450 tons of coal, as per bill of lading, were shipped at Greenock, consigned to Messrs. Tod, Finlay, & Co., of Rangoon. The coal was hard steam coal from different mines. I was by the ship all the time she was being loaded, with the exception of two days, when I was absent at Liverpool. There were two ventilators, one close to the main hatch, and the other by the after hatch. The ventilators were placed just outside of the coombings of the hatches. The after hatches were nearly always off, and so were the forward hatches. Three ordinary ventilators led to the hold from the deck. They were fixtures. The hatches were not battened down till we met with some bad weather in the Bay of Biscay. Then they were taken off, coming through the N.E. trades, and put on while the rain lasted at the Equator, and the main hatches were not taken off till they were lifted to discharge coal overboard. The after and fore hatches were kept off on every possible occasion. There was very little coal in the fore hold. Three 'tween deck beams in fore hold abaft the foremast were visible.

I heard that an inspector attended the ship at the time of loading, I believe on the part of the shipper of the coal; and I was told he expressed himself satisfied with the ventilators. I do know his name.

The ship was insured last year for 6,000*l.* (30,000 dols.) in America. The policy expired in October 1870, and I am not aware to what amount (if at all) she is insured at present. I am a part owner in the ship to a three-sixteenth share. The only insurance I know is 1,100*l.* advanced on the freight of the vessel for the voyage in which she was lost.

EDWIN FRY.

Before me, this 26th day of January 1871,
W. F. PRIDEAUX,
Asst. Res. and Magistrate.

Re-examined on his former oath.

I have been engaged in carrying coal for several years in one ship, the "Evening Star." I carried six cargoes to the West Indies without a ventilator of any description.

I consider the means of carrying coal as employed in vessels going round the Cape as quite insufficient, for the following reasons:—

1st. That they have not, as a rule, 'tween decks laid fore and aft, so as to separate the cargo. The "Beacon Light" had no 'tween decks.

2ndly. Because different kinds of coal are shipped on board the same vessel. I consider that only coal from one mine should be shipped on one vessel, as different kinds of coal generate different gases.

3rdly. Without fore and aft ventilation I do not consider it safe to carry coal on a long voyage.

I have arrived at these conclusions since the loss of the vessel and in consultation with the master of the ship "Northfleet."

The name of the second mate who was drowned is Joseph Dixon, of Liverpool, England, and of the seaman John Thomson, a Norwegian.

Of the remainder of the crew August F. Rabé, carpenter, of Germany, and Andrew Wilson, able-bodied seaman, of Norway, went on board the American whaling barque "Xantho," of New Bedford, U.S., Captain Lavars, on November 21, 1870.

There were three boats on board at time of explosion—a longboat, pinnace, and gig. The longboat was sufficient to carry crew. At time of casualty all plain sail to topgallant sails was set.

EDWIN FRY.

Statement of GEORGE STOUT, taken on oath the 26th day of January 1871 which said deponent saith:

I hold a certificate of competency as first mate, No. 87,137, and served as chief officer on board the "Beacon Light."

The statement handed in by the captain, which was read out, is correct.

I joined the "Beacon Light" as first mate about a week before she sailed.

I corroborate as correct the evidence given by the captain with regard to the ventilators and hatches which is now read over to me.

The last of the coals were being taken on board when I joined the ship.

In my opinion, nothing could have been done otherwise than what was done by the master. If the accident occurred over again, I cannot suggest any other means for extinguishing such a fire.

GEORGE STOUT.

Before me, this 26th day of January 1871.
W. F. PRIDEAUX,
Assistant Resident.

Statement of ALBERT JACKSON, taken on oath this 26th day of January 1871, which said deponent saith:

I was steward on board the ship "Beacon Light."

I have heard the statement made by the captain regarding the ventilators and hatches, and it is correct in every particular.

ALBERT JACKSON.

Statement of JAMES WEIGHT, taken on oath this 26th day of January 1871, which said deponent saith:

I was an A.B. seaman on board the ship "Beacon Light."

I have heard the statement made by the captain regarding the ventilators and hatches, and it is correct in every particular.

JAMES WRIGHT.

Statement of ROBIE SOUTH, taken on oath this 26th day of January 1871, which said deponent saith:

I am an ordinary seaman on board the ship "Beacon Light."

I have heard the statement of the captain regarding the ventilators and hatches, and it is correct in every particular.

ROBIE SOUTH.

Opinion of the Court.

The Court having considered the preceding evidence, are of opinion that the statement handed in by the captain and verified by him upon oath is a true and accurate account of the circumstances attending the loss of the ship "Beacon Light," and that the destruction of that vessel was caused by spontaneous combustion.

They consider that all necessary measures were taken by the surviving officers and crew for the preservation of life, that of property being out of the question, and that no blame is attributable to them in any respect.

The court are further of opinion that the remarks made by Captain Fry at the conclusion of his evidence are worthy the consideration of the Board of Trade, with a view to securing greater safety on board of coal vessels proceeding on long voyages.

The court desires, in conclusion, to express their appreciation of the humane conduct displayed by the master of the ship "Northfleet," in receiving the officers and crew of the lost vessel with such a long voyage before him, and beg leave to recommend him to the favourable consideration of the Board of Trade.

W. F. PRIDEAUX,
Asst. Resdt. and Magt., Aden.
W. K. THYNE,
Conservator of the Port, Aden.

Confirmed,
W. R. S. FITZGERALD,
Governor of Bombay.
Aden, 26th January 1871.

"BERNICE," of Liverpool, a sailing vessel of 1,455 tons register, nine years old, and classed A1 at Lloyds, which class would last until June (1873).

Bombay Fort Police Court,
Friday, 4th April 1873.

Pursuant to the Government notification, Marine Department, published in the Governmeut Gazette of the 3rd instant, appointing John Connon, Esquire, Senior Magistrate of Police, and J. E. Betham, Esquire, master of the ship "Princess Somerwatby," to conduct an investigation into the circumstances connected with the total loss by fire of the ship "Bernice," on Saturday, the 22nd March 1873, in latitude 18° 25′ North, longitude 72° 15′ East, the court assembles this day at 11 o'clock a.m., for the purpose stated.

Mr. PEILE, officiating solicitor to Government, appears to watch the case on behalf of Government.

JAMES STANNUS sworn; examined by Mr. PEILE.

I was master of the late ship "Bernice." I have received a copy of the report on which this investigation is held. I hold a certificate of competency as master, granted by the Board of Trade in 1853, No. 9,179. The ship was registered in the port of Liverpool. Her tonnage was 1,455 and 33. She was a sailing vessel, and was built at St. John's, New Brunswick, in 1864. We sailed from Shields on the 9th October 1872. We had coals on board weighing 1,894 tons and 15 cwt. She was classed A1 at Lloyds, which class would last until June next. I believe the ship was insured. I know nothing about the cargo.

All due and possible precaution was taken with reference to ventilation. There were trunk ventilators at each hatchway, which communicated with fore and aft trunks in the lower hold. I had eight deck ventilators. I have had much experience in hot climates in carrying coals. I never saw a cargo of coals better stowed than this. The coals were dry when they were taken on board, and it was dry weather when they were so taken on board. We had very light winds and hot weather, and made slow progress. Up to the 17th March last there had been no indication of any heating or fire among the coals, and the water in the tanks which were stowed amongst the coal in the after part of the ship remained quite cool. On the 17th March the ship was in latitude 15° 53′ North, longitude 72° 34′ East. At 6 o'clock that morning, in consequence of what the chief officer told me, I went into the fore hold with the chief mate. I cleared away some coal; smoke and vapour were coming out just abaft the foremast. I immediately commenced pouring water over the coals. I put the hatches on, and closed the ventilators in all places to exclude the air. We kept pouring water down night and day, till the flames drove the men away from the pumps. On the 19th March, about 4 o'clock in the morning, an explosion took place, blowing the decks up from the main hatch forward. It blew all the hatches and skylights up, and also the house forward occupied by the men. Several of the men were hurt, two rather severely. Two of the men are now in hospital, and are getting better. After the explosion a great deal of vapour was coming out of the fore part of the ship. The barque "Ocean Belle" was seen that morning, and I signalled to her to come up and remain by us. She did so till we left the ship. On the 22nd, about 6 o'clock in the morning, the flames broke out all over the ship, driving the men away from the pumps, and at 7 o'clock that morning the crew left the ship. I stopped there half-an-hour longer. The foremast had fallen before I left, aud about five minutes after I left the other two masts came down. The ship was all in flames fore aud aft. I and the the crew went on board the "Ocean Belle." The "Ocean Belle" remained near the wreck all day. In the middle of the day I went as close to the "Bernice" as I could safely get, and saw that she was a mere shell. There was a great mass of fire and very little smoke. From the time I discovered the fire I did my best to reach Bombay, hoping to keep the fire under till then. The coals belonged to the Peninsular and Oriental Company, and their own surveyor superintended the shipping of the coals in Shields.

By the Court.

I know the ship was insured, but I do not know anything about the cargo. I do not know the amount the ship was insured for; I got instructions about the insurance of the ship. The ship was drawing 22 feet 4½ inches aft, and 22 feet 2½ inches forward. In my judgment the ship was not overloaded; she would have carried 2,000 tons easily. She had 1,894 tons on board. I had every assistance and kindness from the "Ocean Belle." The crew were under proper control. I have been three years in the "Bernice;" I have seen her deeper loaded with salt. We had five boats on board; they were all in good order and ready for use. I saved four boats and sundry other articles belonging to the ship, which have been sold by auction. I saved my nautical instruments, but lost most of my effects.

James Stannus.

Taken on oath before us,
John Connon,
Senior Magistrate of Police,
J. E. Betham,
Captain of the ship "Princess Somerwatby."

By the Court.

The reason why I stopped the ventilation when the ship was on fire was because I thought and always understood that stopping the ventilation was the best way of preventing fire breaking out.

James Stannus.

Taken on oath before us,
John Connon,
Senior Magistrate of Police,
J. E. Betham,
Captain of the ship "Princess Somerwatby."

Philip Coutanche sworn; examined by Mr. Peile.

I was the chief officer of the ship "Bernice." I was on board when the cargo of coals was taken on board at Shields. The cargo was properly stowed, and every precaution was taken with regard to ventilation. We left Shields on the 8th or 9th October 1872. We had light and contrary winds and the weather was very hot. Nothing particular occurred on the voyage, and there was no indication of heat in the vessel or the coals being on fire until the 17th March. At daylight on that morning I noticed steam and smoke coming out of the fore hatchway, and I immediately informed the captain. The captain and I went below and examined the coals. We moved some of the coals and poured water down where we thought the fire was. After pouring a certain quantity of water on the coals, we put on all the hatches and stopped all ventilation except where we were pouring water down. We continued the pumping night and day, and never stopped. On the 19th, at 4 o'clock in the morning, there was an explosion. It blew the decks up in the fore part, also all the hatches and the forehouse. We continued pouring water down after the explosion. The ship was kept by the wind making the best of her way for Bombay. At 6 o'clock in the morning of the 22nd the flames broke out under the fore house, and then all over the ship. The "Ocean Belle" was near us at the time. When the sails forward took fire the crew left the ship and went on board the "Ocean Belle." I left the ship at half-past 7 that morning. The foremast was then over the side, and the mainmast was tottering and it came down about a quarter of an hour afterwards, and brought the mizzenmast down with it. The ship afterwards broke out in flames all over, fore and aft.

By the Court.

I joined the ship a month before we left Shields, and was on board all the time the coals were being taken on board. We were in the dock. The coals were quite dry. I have been in ships carrying coals before. I have been in two other ships bound for Bombay with coals. I think the ventilation on board the "Bernice" was the best I ever saw. There was no suspicion of fire till the morning of the 17th March. The crew behaved very well till the explosion occurred. They then seemed a little frightened. We were well received by the "Ocean Belle."

Philip Coutanche.

Taken on oath before us,
John Connon,
Senior Magistrate of Police,
J. E. Betham,
Captain of the ship "Princess Somerwatby."

Andrew Dryburgh sworn; examined by Mr. Peile.

I was carpenter on board the "Bernice." I was on board the ship when she was taking on board her cargo at Shields. The ventilating apparatus was all fitted before I went on board. I never saw a ship ventilated before. The other ships I have been on board of made short passages only. The ship was staunch and strong when she left Shields on the 9th October. She was tight all the passage. Up to the 17th March nothing particular happened. I was on board that morning, when smoke was seen coming out of the fore hatch. I and the chief mate went down the fore hold to try and find out where the fire was. We started the pumps pouring water over the coals about an hour afterwards. I think the hatches were put on the next day. We continued pouring water on the coals. The hatches were all put on. I remember the explosion taking place on the Thursday. Smoke was first observed on the Tuesday. The explosion occurred before daylight. The fore part of the ship was blown up. It was a loud explosion; several of the men were hurt. The boats were put out, and then we started pumping again. On the Sunday following flames burst out underneath the house in the fore part of the ship. That morning we left the ship and went on board the "Ocean Belle." Shortly after we left the ship the foremast fell, and about an hour afterwards the mainmast and mizzenmast fell. The flames broke out all over the ship after that.

By the Court.

The captain ordered the hatches to be put on. The ship made no water all the way out. I sounded the pumps every day, sometimes twice, all the way out. It is my practice to do so.

Andrew Dryburgh.

Taken on oath before us,
John Connon,
Senior Magistrate of Police.
J. E. Betham,
Captain of the ship "Princess Somerwatby."

William Elliot Jarvis sworn; examined by Mr. Peile.

I am the master of the "Ocean Belle," lately arrived in Bombay on a voyage from Swansea with coals. On a Thursday morning in March last, in consequence of signals, I passed close under the lee of the ship "Bernice." I was hailed by Captain Stannus, who told me his ship was on fire. I went on board. I found the decks were blown up from the main hatch forward, and the forehouse, and some of the men were lying about the deck injured. There was a little smoke coming out of the hold. I sent my second mate and three hands on board to assist. I could not spare any more hands, as mine is a small vessel. On the Saturday afternoon I took on board my ship the effects of the crew of the "Bernice," in order to encourage them to work. On the Sunday morning, about 6 o'clock or half-past 6, I saw the flames break out on board the "Bernice," in the forehouse. The crew of the "Bernice" then came on board the "Ocean Belle." At the time they came on board all the masts were gone on board the "Bernice." The master of the "Bernice" afterwards came on board. We remained by the ship allday, and about 12 o'clock in the day we went close past her, and I went up into the rigging to look at the "Bernice," and saw she was nothing but a shell and a mass of red hot cinders. All the time from the time I first went to the "Bernice" till the ship was burnt we were making the best of our way to Bombay.

By the Court.

All sail was set on the "Bernice" up to Sunday morning or until the flames broke out on board.

W. E. Jarvis.

Taken on oath before us,
John Connon,
Senior Magistrate of Police.
J. E. Betham,
Captain of the ship "Princess Somerwatby."

Report of the Court.

Bombay Fort Police Court,
Monday, 7th April 1873.

Pursuant to the Government resolution, Marine Department, and notification published in the Government Gazette of the 3rd instant, appointing John Connon, Esq., Senior Magistrate of Police, and J. E. Betham, Esq., master of the ship "Princess Somerwatby," to conduct an investigation into the circumstances connected with the total loss by fire of the ship "Bernice" on Saturday, the 22nd March 1873, in latitude 18° 25′ North, longitude 72° 15′ East, the court assembled for the purpose stated on the dates mentioned in the record of proceedings.

From the evidence adduced before us relative to the loss of the "Bernice" by fire, we find that nothing of any consequence appears to have occurred on board the ship till the morning of the 17th March last, when the ship was within 200 miles of Bombay.

At that time smoke and vapour were seen to be coming out of the hold just abaft the foremast.

The vessel appears to have been properly laden and well ventilated, and all due precautions seem to have been taken to guard against fire. The cargo consisted entirely of coal, of which there were 1,894 tons 15 cwts. on board. The registered tonnage of the ship was 1,455 tons, and the captain says that she was fit to carry 2,000 tons, which we believe. The ship left Shields bound for Bombay by way of the Cape of Good Hope on the 9th October 1872. The ship was thus over five months at sea when the fire was discovered among the coals. We are satisfied by the evidence that the ship was well found, well manned, and equipped, and the long passage is accounted for by light and contrary winds.

When the fire was discovered all possible means were, as appears to us, promptly adopted to extinguish it. But notwithstanding the efforts made by the master and by his officers and crew to save the ship from destruction, the fire made rapid progress, and on the morning of the 19th March, about 4 o'clock, an explosion took place, when the decks were blown up from the main hatch forward, also the hatches, skylight, and deck-house forward occupied by the crew. Several of the men were hurt, two severely.

After the explosion Captain Stannus states that he observed much vapour coming out of the fore part of the ship.

Fortunately the barque "Ocean Belle," an English ship, was seen in the morning the explosion occurred on board the "Bernice," and Captain Stannus signalled to the "Ocean Belle" for assistance, Captain Jarvis of the "Ocean Belle" immediately sent such assistance to the "Bernice" as he could. His men well assisted the crew of the ship in danger to work the pumps in the way of playing water on the cargo, keeping the decks flooded, &c., and we are of opinion that every effort which could have been made was made to put out the fire.

On the morning of the 22nd, however, about 6 o'clock, flames broke out all over the ship. The men were driven away from the pumps by the flames, and at 7 o'clock they were compelled to leave the ship, but they did not do so without the leave of the captain. The captain himself remained on board half an hour longer. Before he left the ship the foremast had fallen, and about five minutes after he left the ship the other two masts fell, the ship being then all in flames fore and aft.

The "Ocean Belle" remained near the wreck all day. In the middle of the day Captain Stannus and Captain Jarvis went as close to the "Bernice" as they could with safety, and saw that the vessel had been burnt down to a mere shell.

From the time the fire was discovered Captain Stannus made every effort to reach Bombay, thinking that he might possibly keep the fire under till then and be able to save his ship.

In view of all the facts as they have appeared before us in evidence, we consider that the destruction of the "Bernice" was caused by spontaneous combustion among the coal, which may have been owing in some measure to the long time the ship was at sea before she got near Bombay.

We are of opinion that no blame attaches to the master of the "Bernice," or to his officers or his crew. They have been the victims of a common misfortune, and all seem to have worked with judgment and care in their respective positions, and did all they could do to extinguish the fire and save the ship.

The captain of the "Bernice" holds a certificate of competency from the Board of Trade dated 20 years ago, and under the circumstances narrated in this report, and referring to the evidence taken before us, of which evidence we submit full notes, we have not thought it necessary to detain this certificate, though it was duly tendered us, and we have accordingly returned it to him.

We wish to add a word as to the captain of the "Ocean Belle." He seems to us to have behaved under the circumstances with most considerate humanity, and although that is not more than we should expect of any British seaman, we are of opinion that both before and after the disaster (as he brought the captain and crew of the lost ship all to Bombay in his own small ship and treated them well) he deserves honourable mention, that his conduct should be brought to the notice of the Government, as we now respectfully bring it, and that if the Government is so pleased, it should be brought to the notice of the Board of Trade as well.

John Connon,
Senior Magistrate of Police.
J. E. Betham,
Captain of the ship "Princess Somerwatby."

Bombay Fort Police Court,
7th April 1873.

Confirmed,
J. Wodehouse.
May 5th, 1873.

"COUNTY OF NAIRN," of Glasgow, of 990 tons register, four years old.

Report of the proceedings at a Court of Inquiry held at the office of H.B.M. Acting Vice-Consul at Sourabaya on the 23rd day of August 1873, for the purpose of investigating the circumstances attending the loss of the British ship "County of Nairn," of Glasgow, Richard McKenzie, master.

Present:

Alexander Hadaway, H.B.M. Acting Vice-Consul, President.
N. McVicar, partner of the firm of Messrs. Martin, Dyce, & Co.
James Greig, procuration holder of the firm of Messrs. Pitcairn, Syme, & Co.
Alexander McNab, master of the British ship "Daniel Rankin."

The president, having duly sworn the members of the court, explained to them the nature of the inquiry about to be instituted.

Captain McKenzie was then called and duly sworn, and in reply to questions put by the court, stated that he was 46 years of age. Had held a master's certificate for 16 years, and had been 6 years in the employ of the owners of the "County of Nairn." He once before had an accident with a vessel under his command; it was in 1859, and happened on the west coast of Scotland.

On being requested by the court to state the circumstances connected with the loss of the vessel, Captain McKenzie referred to his logbook, the entries in which from the 12th to the 16th August were then read out by the president as follows:—

Tuesday, the 12th August 1873.

Courses.	Winds.	
S.E. by E.	N.N.E.	a.m. Light wind and very
S.E. by E.	East.	variable. 2 a.m. steady; 8, tacked ship; 8.30, galley caught fire; it was soon put out, doing little harm; people variously employed.
S.S.E.	"	Noon, tacked ship; 1 tacked
S. by E. ½ E.	E. ½ S.	ship. p.m. Discovered smoke issuing from the coals on port side of main hatch; called all hands; passed pig iron on deck; removed boxes, crates, &c; from place around the smoke; played water on it.
E.S.E.	N.E.	5. Passed the powder on poop, and covered it the best we could with sails, tarpaulings, &c.
N.N.E.	—	Latter port, water kept playing on it to keep it down.
		11. Hard breeze came off, tacked ship to Eastward.

Wednesday, 13th August.

N.E. by E. ½ E.	S.E. ½ E.	a.m. Moderate breeze and clear weather. 4 a.m. do. do. 6 a.m. Crimon Java,
N.E. by E.	S.E. by E.	bore N.N.W. 4 miles; found the smoke coming
E.N.E.	S.E.	out all over in square of main hatch; cleared all
E. by N.	S.E. by S.	cargo out of the road, and kept water going on it;
S.W. by S.		it feels very warm; all hatches are on but one of the hatches at the main
South.	E.S.E.	for to get water down.
S. by E.	E. by S.	The smell of gas is so strong that it almost chokes the people in the hold. Noon, fine breeze; p.m., moderate breeze and fine clear weather.
		2 p.m. Tacked ship.
		Still playing water on the coals; they are getting much worse.
		11 p.m. Tacked ship.
		Still keeping going; smoke all over the deck; can't sleep in forecastle for gas.
		Midnight. Squally with rain; pumps attended to

Thursday, 14th August.

Courses.	Winds.	
S.E. ½ E.	S.S.W.	a.m. Fine breeze and clear weather. 4 a.m. Do. do. do.
S.S.E.	S.W.	There is smoke coming out all round the mainmast; took more pig iron.
S.E.	Variable.	On deck and shifted more cargo, keeping water on it.
		10 a.m. People cannot stop below, it is increasing so very fast. Smoke is like to suffocate us about main hatch; there is smoke coming out of all three lower masts heads, and
		p.m., now fearing that the coals are become ignited, judged it is prudent to make for the western channel to Sourabaya, to scuttle ship on bank, and get assistance. 6·46 p.m. Tacked ship to S.E.; at 9 p.m., sighted light-ship; at 9.30, wind hauled off the land, which taking the ship aback, obliged us to come to anchor in 7 fathoms water, with 30 fathoms chain on port.
		Light-ship bearing S.E., Panka Point S.W. and while in the act of clewing up the sail, flames burst up the main hatch; at once the order was given to heave gunpowder over board, and then to get out the three boats on beams aft; left the ship and lay by her; flames half up the mainmast.

Friday, 15th August.

		a.m. Flames stopping, judged it safe to board the ship; hove short and made sail ready to run the ship on the bank. 6 a.m. Spoke the schooner "Duke of Richmond," bound to Sourabaya; desired him to report ship on fire, and we did intend to scuttle her. Wind came in favour, weighed anchor, and proceeded towards the bank; wind light and coming right out, at the same time tide being against us we had to let go anchor again in 5 fathoms water; all keep playing water on fire. 11 a.m. Received on board a pilot; sea-breeze came strong, which caused the flames to increase very fast in the hold, but it keeps under hatches. 1 p.m. Tripped anchor and run the ship on shore, Panka Point.
		Bearing W. ½ S. ½ a mile; two anchors let go and bored holes to scuttle ship; while in the act of scuttling her, ship burst out in flames, forcing us to take to the boats as fast as we could assisted by two of the Panka pilot boats, saving but very little, amounting to gig, pinnace, and life-boat, with their gear, several bolts of canvas, chronometers, barometers, and compass landed with boats at Panka Point, ship being in one complete mass of flames fore and aft.

Saturday, 16th August.

		a.m. Daylight, all masts over the side, and giboom and hull of the ship burned to the water's edge; ship not being full of water to cover all the fire, made carpenter cut large hole to let water run in faster, which completely scuttled her; finding that nothing could be saved, got boats from Resident of Sedayoe, and proceeded to Sourabaya with crew, leaving the wreck of ship in charge of the Resident, with orders to keep a strict watch till further orders.

We, the undersigned, hereby certify that the above is a true and correct copy of the log-book of the "County of Nairn" from the 12th to the 16th August.

ALEX. HADAWAY,
H.B.M.'s Acting Vice-Consul.
NEIL MCVICAR,
Partner of the firm of Martin Dyce & Co.
JAMES GREIG,
Procuration holder of the firm of Pitcairn, Lyme, & Co.
ALEX. MCNAB,
Master of ship "Daniel Rankin."

CAPTAIN MCKENZIE stated further: Shortly before noon on the 12th, we lay a little to the west of the Island of Carimon, Java. I then steered for land due south, a light wind blowing from E. ½ S., but later on a land breeze springing up, I was forced to sail off land. Until the 13th, I did not look upon the fire as serious, and then from the position of the ship and the direction of the wind, it was easier to make for Panka Point than Samarang. When the log-book says the galley was on fire, it is incorrect, it should be a fire was in the galley. It was of a trifling nature, and was caused by the upsetting of some fat out of one of the pans into the fire. The woodwork over the fire was merely blistered; no sparks could possibly have come out of the galley and supposing a few had, it was impossible that they could have reached the hold. When the smoke first appeared, I accounted for it that the coals were either on fire or smouldering. I consider that there was sufficient ventilation for the coals on board. Altogether there were 600 tons, and they were stowed in two portions, one portion consisting of 400 tons was stowed directly under the main hatch and separated from the other portion, consisting of the remaining 200 tons, by a pile of crates. Both portions were about 13 to 14 feet deep at their deepest part, gradually tapering off towards the fore hatch and stern respectively. I am unable to say whether the coal was damp when taken in. When the smell of gas was first reported, I went below, and seeing nothing, ordered the hatches to be left open to carry away the smell. When we tacked at noon on the 12th, the hatches were still open, but they were afterwards closed. I have often carried the same quantity of coal with no better ventilation. I tried to get up a portion of the cargo, first passed up the gunpowder, after which we found it impossible to remain below. I then proceeded with all despatch to reach Panka Point, on purpose to scuttle the ship, which was the only way of saving either ship or cargo. I had pumps and a fire-engine with a long hose, all of which were in good order; we had also a good supply of buckets, which were used.

WILLIAM THIRD, first officer, was now called, and having been duly sworn, deposed as follows:—

I am 31 years of age. I have held a master's certificate for two years, Have been 17 months on board the "County of Nairn." The log-book was written by me, and I confirm its contents. When the fire in the galley took place, the cook, who acted also in the capacity of steward, was aft attending the captain and myself at breakfast. The paint in the galley was merely blistered, no other damage was done; and by the time the captain and I got forward, the fire had been put out. I am unable to account for the coals getting on fire, the ventilation was good, in fact better than in most vessels in which I have served.

He confirmed Captain McKenzie's statement as to the manner in which the coals were stowed.

The fire must have commenced in the coals stowed directly under the main hatch. The crates being stowed between the two lots of coal would assist the ventilation, the masts were ventilators, as they were of iron and had the usual holes, which I know were not plugged up, as when stowing the coal, I myself had them cleaned out. The coals were dry when taken in. I have often been in coal ships before, and in some without any ventilation whatever. While in Batavia the coals were never touched, neither was there any smell of gas detected.

He confirmed Captain McKenzie's statement as to the first discovery of smoke. When the pig iron, boxes, &c. had been cleared away, I distinctly saw smoke coming up through the coal. I have no reason to suppose that there was any carelessness on the part of the crew. It was impossible to scuttle the vessel before we did. The holes for scuttling were all bored from the outside. An unsuccessful attempt was made to save the sails, but it was impossible attempting to save any of the cargo. Between decks fore and aft she was one mass of flames. I cannot understand how it was she lasted as long as she did; and when the flames did burst out, I had to spring off the bows to gain the boats.

ROBERT BREMNER, second mate, was now called, and having been duly sworn, gave the following evidence:—

I am 25 years of age. I hold a first mate's certificate, and have served for about two years in this vessel. It was my watch when the smell of gas was first detected. It was reported to me by Collins, who had opened the fore hatch in order to go below for a small piece of wood. I tried to go down the fore hatch, but the smell of the gas almost choked me. I went and reported to the captain. The vessel was well ventilated. The masts were not plugged. I consider the mainmast was a good ventilator.

He confirmed Captain McKenzie and the first mate as to the stowing of the coal. The coal was dry when taken in; cannot say cause of fire. In Batavia, I was in the hold every day for 12 hours, and there was then no sign of anything going wrong.

When we tacked on the 12th, this being about the time the smoke was first discovered the hatches were open. There was no carelessness on the part of the crew which could have occasioned the fire. The fire in the galley was nothing; it was no fire at all.

COLLINS, A.B., was now called, and having been duly sworn, deposed as follows:—

I am a Canadian, and am 30 years of age. I went to the forehatch for the purpose of going below to get a piece of wood, but upon lifting the hatch, the smell of gas was so strong I could not descend. I then reported to the second mate, who went forward to see what was the matter. I was never before in a vessel laden with coals. From what we could see by digging in the coals through which the smoke was issuing, and which at first were not so hot as to prevent our standing on them, it is my opinion, and that of the rest of the sailors, that the fire was at the very bottom of the coals. I saw smoke coming out of the masts.

What Collins stated with respect to galley fire confirmed Captain McKenzie's statement.

JAMES LESLEY, carpenter, was now called, and having been duly sworn, stated as follows:—

I am 23 years of age, and have served three and a half months on board the "County of Nairn." I previously served on board a steamer. He confirmed Captain McKenzie's statement in regard to fire in the galley. When smoke was first reported I was at my usual work. I consider there was sufficient ventilation. I know nothing about the stowage of the cargo. I joined the vessel the day she sailed. It was I who scuttled the vessel. I worked first from a boat, afterwards from a stage slung on the outside of the ship, and as the swell rose and fell I was sometimes almost submerged, in fact it was with great danger to both life and limb that I succeeded in doing what I did. I bored five holes 1¼ inches in diameter in each side of the vessel, having first removed the copper. There was no possibility of cutting out a square block. I consider my best was done to scuttle the vessel; in fact there was no other way. The vessel was well supplied in case of fire.

CHARLES MARSHALL, A.B., was now called, and having been duly sworn, deposed as follows:—

I am 37 years of age. Have served three and a half months on board the "County of Nairn." I was at the wheel when smoke was first reported. From 12 a.m. to 2 p.m. we were on the starboard tack. I saw smoke coming up through the coal from underneath the beams. Everything was done that could be done to put the fire out.

JOHN RUSSELL, cook and steward, was now called, and having been duly sworn, gave the following evidence:—

He confirmed Captain McKenzie's statement in regard to origin of the fire in the galley. The paint which was blistered had not fallen off, and did not come off until I had scraped it off. I never before went as cook and steward.

ARCHIBALD GRAHAM, boatswain, was now called, and having been duly sworn, stated as follows:—

I have been three and a half months on board the "County of Nairn." I have been four years at sea. It was not my watch when the smell of gas was first discovered. I was below when the smell of gas was reported. The captain went down forward and came up aft, but could see nothing.

We were tacking the ship when smoke appeared. The hatches were open, but they were afterwards closed. There was no carelessness on the part of the crew with regard to lights.

Decision.

We, the undersigned, having duly weighed the evidence adduced, give it as our opinion that the loss of the British ship "County of Nairn" was caused by fire, the origin of which is unknown, but supposed to be spontaneous combustion of the coals in the lower middle part of the ship. Considering the limited quantity of coals on board, and the manner in which they were stowed, we are satisfied that the means of ventilation were sufficient, and that everything that could be done was done, after discovery of the fire, to put it out. We are further of opinion that, from the position of the ship and direction of the wind at the time the smoke was discovered, the captain acted rightly in steering the course he did, and finally scuttling the ship at Panka Point. We thus exonerate Captain Richard McKenzie from all blame, and consider that he and his officers acted with energy and judgment throughout.

ALEX. HADAWAY,
H.B.M.'s Acting Vice-Consul, President.
NEILE MACVICAR,

"PRINCE ALFRED" Barque, of Shoreham, of 368 tons register, 5 years old, and classed at Lloyds A1 9, years.

Proceedings of the Mauritius Marine Board in the case of the bark "Prince Alfred" of Shoreham, of the burthen of 368 tons, Henry Puttick, master, which vessel was burnt in latitude 23° 30′ S. and longitude 79° 56′ E. on the 31st August last, on her voyage from Hull to Point de Galle.

The Board assembled at the Port Office on the 14th September 1873.

Were present:

JOHN MORGAN, Esq., Acting Harbour Master and President.

J. COWIN, Esqre., W. A. BARCLAY, Esq., J. P. ELLIS, Esqre.	Marine Surveyors.

Assisted by:

Captain T. MILES, Barque "Umvoti."

Presented themselves for examination:

Henry Puttick, master; James Saunders, mate; Peter Thomson, boatswain; Jelmar Wilkman, A.B., of the late barque "Prince Alfred."

The following documents were laid before the Board:—

1. The Official Log book.
2. The Chart by which the vessel was navigated.

All the evidence was on oath.

HENRY PUTTICK sworn:

39 years old; born at Shoreham. Have been 19 years to sea. Have been in command about 8 years. Have a certificate of competency. Have been 2½ years in command of the barque "Prince Alfred." The vessel was built at Shoreham, in 1868. She is, I believe, not insured; classed at Lloyds A1, 9 years; docked and re-metalled in May last at Hull. The vessel was in a proper and seaworthy condition when she left home; continued so throughout, up to the time of the accident. Smoke was first seen on the 30th August, no symptoms before that. At 5 a.m., on the 30th August; the first indication of fire was in the forecastle, reported by the men to the mate and afterwards to me, and I came on deck and saw smoke coming out of the forehatch. I went down in the hold and felt the coals; they appeared quite cold. We then took off the main hatches and trimmed cargo on deck, from 15 to 20 tons; about 4 feet down found the cargo quite hot. We poured water in about one hour and a half, it getting so hot, that the men could not stop down. No ventilation through the cargo. We shortened sail, hauled up the courses, hove the ship too, main topsail aback, and battened down all hatches. The vessel was going free. I did all in my power to save ship and cargo. The vessel was from Hull with a cargo of steam coals for Point de Galle. My vessel was inspected by Lloyds' Surveyor to take in any cargo. We then put out the long boat, provisioned her, passed her astern with two men remaining in her, the remainder stopping on board the ship. At 3 a.m. on the 31st of August, fire broke through the port covering board between the fore and main rigging; put out the small boat and laid by the ship till daylight, then myself and one man went on board and found her burning furiously. I went down in the cabin to get some more provisions and the man with me; smoke being so suffocating that I could hardly get up the ladder, when I got in the air I fell down insensible and the man having to heave water over me to bring me too, sufficiently to get in the boat. About noon on the 31st of August I abandoned the ship in latitude 24° 30′ S. and longitude 79° 56′ E. the ship being on fire and burning furiously. No smell of gas or sign of smoke previous to the 30th of August. I do not know the quality of coals put on board. It was rainy weather at the time they were shipped. I have taken many cargoes of coal before; never used ventilators through the cargo; was neither suggested to me, nor did I consider it necessary this voyage. I beg of the Board to record my grateful thanks for the humane and kind treatment I received myself and crew from Captain Pichon of the French barque "Boussole" from the time he picked us up till he landed us here in the Mauritius, which caused a serious deviation from his voyage.

JAMES SAUNDERS sworn:

31 years old, born at Shoreham. I have been 15 years at sea. I have been mate of the barque "Prince Alfred" for 2½ years, and have been 5 years as boatswain and mate in other ships. I was on board the vessel when she was in dock and re-metalled. Rainy weather when the coals were shipped. The vessel was tight and in a proper and seaworthy condition, and continued so throughout till the accident. At 5 a.m. on the 30th of August, smoke first reported to me by the men in the forecastle and I reported it to the captain. There being a nasty smell of gas in the hold, took off the hatches and trimmed cargo on deck; finding the coals quite hot about 4 feet under the main hatch, put down water, trying to stop it, could not succeed, and the cargo getting so hot, that the men could not stop in the hold, put on the hatches and battened down, ship going free. Took in sail and hove the ship to; got the long boat ready, put her out, provisioned her, and passed her astern with two men in her, the remainder stopping on board. About 4 a.m., on the 31st August, saw the fire coming up through the port covering board amidships; put the small boat out and laid by the ship till daylight, when the master and one man went on board and found the ship burning furiously. The master and man went in the cabin to get more provisions, the smoke being so suffocating that they could not stop. The master on getting on deck fell insensible, the man having to heave water over him to bring him to. (This information I got from the man who accompanied the captain.)

We tried to extinguish the fire by pouring water in the fore and main hatch for an hour and a half, but without avail. I beg leave to bring to the notice of the Board the kind and humane treatment we all received from Captain Pichon and his men of the French barque "Boussole" from the time we were picked up till the time we landed in the Mauritius.

PETER THOMSON sworn:

27 years old. Boatswain of the barque "Prince Alfred." Born in Iceland; joined the vessel in May ultimo, at Hull. The ship was loaded when I joined her. The vessel was in a proper and seaworthy condition to the time of her accident. She was not overladen. Smoke was first seen in the forehatch; opened the forehatch first and smelt a nasty smell. The crew lived in the forecastle. Poured water down in the hold for about 2 hours; trimmed cargo, put coals on deck from the main hatchway; found the coals too hot and the men could not stop down below. Battened the hatches down, took in the small sails, hauled up the courses, and hove the vessel too; main topsail aback, got the things ready for the boat. The captain ordered the long boat to be put out, provisioned her and passed her astern. Two hands were in the boat. We left the ship at 4 a.m., fire was through the covering board, pitch was boiling out the seams of the deck, the deck was so hot so that we could not stand on. The captain, in my opinion, tried all he could to save the ship and cargo. There were no signs whatsoever of smoke or gas until the morning of the 30th August.

JELMER WILKMAN,

Born in Sweden. 22 years old; A.B. I joined the vessel at Hull, the vessel being laden. I have been three years to sea. The vessel was tight and in a proper and seaworthy condition from leaving Hull to the time of her accident. I smelt the smoke in the forecastle at 4 a.m. I came on deck, and at 6 a.m. I took the wheel and saw the smoke coming from the fore hatchway; water was poured down in the fore and main hatchways. The coals were taken out and the water was poured down. The coals were so hot that I could not remain below and the farther I went down the hotter it became. When I came up the captain gave the orders to batten the hatches down and shorten sails; sails were shortened and vessel hove to. We got the long boat out ready, provisioned, and passed astern, and put two men in her. Remained on board till Sunday at 4 a.m. When we left the ship, the fire came through the covering board from the port side, with great quantities of smoke. At about 10 a.m. again boarded the ship with the captain to try to get some more provisions. When we got on board the cabin was full of smoke. I assisted in putting the bread in the boat, and on my return I found the captain lying on the deck senseless, and blood running from his nose. I took a bucket of water and hove it over his head, which brought the captain round. We then left the vessel. We were in sight of the vessel all day, and at night time there was a glare.

Report.

The "Prince Alfred" was built and registered at Shoreham, in 1868; official number 58,023, and classed A1 9 years at Lloyd's; she was flushdecked, barque rigged, and 368 tons register. She was owned by Thomas Gates, Esq. shipowner, of New Road, Shoreham, and commanded by Mr. Henry Puttick, who holds a certificate of competency as master mariner, number 89,520, and was bound from Hull to Point de Galle (Ceylon) with a cargo of 614 tons of steam coals. The "Prince Alfred" left the Humber on the morning of the 5th of June. She was then tight, staunch, and in every way seaworthy, and continued so up to the time of her loss. The voyage was successful up to the 30th August, when smoke was observed in the forecastle, and on examination, it was evident from the heated temperature that combustion was going on; the hatches were taken off, and water was freely poured down the forehold on the coals. About 15 tons of cargo was dug out of the main hold, and hove on deck, in the hope of getting at the real seat of the fire. The men remained at work till driven on deck by the heat and the rapidly increasing volume of gas and smoke; it was then 8 p.m., the hatches were ordered to be put on and battened down, the light sails and courses clued up, and the vessel hove to; the long boat was then got out and rigged, her sails and rigging being below; a small supply of provisions and water was put into her and she was passed astern with two men in her, the rest of the crew remaining on board, still hoping that the fire might smother. At 4 a.m., on the morning of the 31st, the fire broke through the covering board on the port side amidships, the jolly boat was then put out and the master and crew left the vessel and took to the boats, but remained by her until daylight when the master and one of the crew went on board to try and get some more provisions and found the vessel burning with great fury; the master went down in the cabin, the smell and smoke almost suffocating him. He just managed to crawl on deck when he fell down senseless and bleeding at the nose. The man that was with him had the presence of mind in heaving water over him, which brought him sufficiently round to get him back into the boat. At noon, finding the ship to be hopelessly on fire, and having only a small supply of provisions and water, the nearest land being Rodrigues, which was 1,000 miles off; they left the vessel; Mauritius then bore from the west 1,388 miles. The master was the last to leave and the whole proceedings, in the opinion of the Board, are marked with judgment and prudence and highly commendable. As the jolly boat, which was in tow of the long boat prevented their progress she was cast off and turned adrift on the 7th day after leaving the vessel. Having gone a distance of 900 miles they were when in latitude 19° 39′ S., longitude 62° 30′ E., fortunately picked up by the French barque "Boussole," Captain René Marie Pichon, who treated them with great kindness.

The Board cannot close this report without reminding the authorities of the great want of precaution in loading a combustible cargo, such as coals, without the vessel being properly ventilated; this ought to be made compulsory on vessels accepting charters to carry coals on a long passage. Here is a fine vessel lost, valuable lives risked, whereas, if ordinary precautions of ventilating the vessel had she been attended to, she might have been saved.

The Board are therefore of opinion that the evidence on oath of the captain, officers, and of the crew, is a true and accurate account of the circumstances attending the loss of the "Prince Alfred," and that the destruction of the vessel was caused by spontaneous combustion, and consider that all necessary measures were taken by them to extinguish the fire, and that no blame whatever is attached to the Captain, officers, and crew, and have much pleasure in returning Captain Henry Puttick and Mr. James Saunders, chief officer, their certificates.

The pleasing duty now remains of recording the generous and hospitable treatment received by the master, officers, and crew of the unfortunate "Prince Alfred" from Captain René Marie Pichon, of the French barque "Boussole," to which ample testimony was borne in receiving them on board of his vessel, having a long voyage before him, and having come out of his course to land them here, by which his vessel would lose at least four days; we therefore beg leave to recommend him to the favourable consideration of the Board of Trade.

John Morgan,
Acting Harbour Master and
President of the Board.
John P. Ellis,
John Cowin, } Marine Surveyors.
A. W. Barclay,
Thos. Miles,
Captain of the barque "Umvoti."

"ST. MUNGO," of Glasgow, iron ship of 1,375 tons register, eight years old, classed A1 for 21 years.

Proceedings of the Mauritius Marine Board in the case of the ship "St. Mungo," of Glasgow, of the burden of 1,375 tons, Frederick Broom, Master, which vessel was burnt in latitude 34° 57′ South, and longitude 20° 18′ West, on the 13th September last, on her voyage from Dundee to Point de Galle.

The Board assembled at the Port Office on Monday the 20th October 1873.

Were present:

John Morgan, Esq., Acting Harbour Master and President.
John Cowin, Esq.,
W. A. Barclay, Esq., } Marine Surveyors.

Assisted by:

Captain J. Anderson, barque "Lorton Vale."
Captain W. H. Metcalf, ship "Beechardass Ambaidass."

Presented themselves for examination:

Frederick Broom, master; John Henry Buckler, first mate; Alexander Scott, second mate; William Ross, steward; George Wilkie, carpenter; Charles Reilly, A.B.; John Miller, A.B., of the late ship "St. Mungo."

W. H. Hathorne, master of the American barque "Taria Topan."

The following documents were laid before the Board:—

1. The official log-book.
2. The chart by which the vessel was navigated.

All evidence was on oath.

Frederick Broom sworn:

30 years old; born at Rochester; holds a certificate of competency. Has been to sea 16 years. Has been 12 months in command of the ship "St. Mungo." Was my first command. The vessel was insured; she was built in 1865; she was classed A1 21 years. The vessel was tight, and in a proper and seaworthy condition when leaving Dundee. First symptoms of smoke were seen on the morning of the 13th September. The vessel left Dundee on the 9th July; had a full cargo; was not overladen; she had about 500 tons of coals in the tween decks; her draught of water was 20 feet 3 inches when we left. No symptoms of smoke or smell were discovered before the morning of the 13th September. The ship was well ventilated (nine ventilators), one ventilator went down through each hatchway down to the kelson, two on the poop went through the main deck, two through the main deck between the fore and main hatchways, two through the main and top gallant forecastle deck. After the first appearance of smoke my first order was to get all stores of a combustible nature upon deck; whilst that was being done, I went down in the hold accompanied by one of the seamen. The steward, William Ross, was the first person who saw the smoke at 8.15 a.m., on the 13th September, issuing from the after-hatch ventilator and reported it to me. I could not stop long down the hold on account of the smell of the gas, and had great difficulty in getting on deck again. The man Robertson was with me, but he did not appear to be as much exhausted as I. When I came on deck I ordered everything to be battened down. During the time they were battening down hatches I went down the three ventilators followed by the chief officer, and found cool from kelson to about six feet up, the smell of the gas being so strong below that no one could stand to work. No wet coals were taken on board at Dundee. 4 p.m., everything appearing cool and no smoke observable, I had one of the ventilators on the poop opened to allow the foul air, if any had generated, to escape. I allowed it to remain off for a short time and then put it on again. After this precaution I felt no fear of an explosion. At

8 p.m. the crew came aft and asked me to close on a barque which had been in company with us to windward all day, but I had already altered my course so as to keep her in signal distance. At 10 p.m. and also at midnight there appeared to be no presence of fire. At 3 a.m., the fore, main, and after hatches blew off with a terrific roar, and a flame leaping half way up the mainmast and immediately going out, but dense volumes of smoke arising from all hatches. I immediately set all hands drawing water and pumping with both force pumps down the mainhatch, and cut holes in the deck as well, and as soon as the smoke had partly cleared, I made a line fast round me and got into the hold, but still could see no traces of flames, but conclude it was in the body of the ship. At 5.30 a.m. we sighted the barque "Taria Topan," and bore down upon her and asked him to stop by me. I also sent a boat for the captain and got him on board and showed him the exact state we were in and agreed upon signals in case of us being compelled to obtain his assistance, intending in my own mind to try and get the ship into the Cape. The crew said that they would work with greater will if we steered so as to sight Tristan d'Acunha or the nearest land, and if the ship was then safe, they would do their utmost to get her into the Cape. This was agreed upon by myself and the captain of the barque. Every effort was made to get the fire under, but it was of no avail. At 2.30 p.m. the men said they saw no abatement; in fact, the fire was increasing, and they wanted to leave the ship, but I got them to try again with a will for one hour, and then I would see what was to be done (myself and the officers heaving coals overboard, trying, if possible, to get nearer to the fire, but we had to desist on account of the sulphur). At 3 p.m. the flames burst through the deck out of the starboard-chain-locker, quickly spreading all over. Seeing that no more could be done to save the property, and deeming it necessary for the preservation of life, I signalled the barque to close and gave the order to get the boats out and abandon the ship, which was effected by about 6 p.m., by which time the ship was in flames fore and aft. At about 8 p.m., as could be seen, there was only the mizzenmast standing, and it on fire. At 10.30 p.m. the boats being secured, the captain filled on his vessel, the flames could be seen up to about 12.30 a.m., the barque going at the rate of nine knots per hour.

In concluding my evidence, I cannot omit to testify to Captain W. H. Hathorne, his officers and crew, my sincere gratitude for the aid and assistance they kindly lent me on the occasion, and for the hospitable and generous manner in which we were all treated whilst on board his vessel.

John Henry Buckler sworn :

52 years old; born in Sussex. I hold a certificate of competency as master. I have been nine years at sea, since last August. I have been four years as second mate and mate. I have been two years as chief mate of a vessel. Since last July I joined the ship "St. Mungo" at Dundee, a fortnight before she left; when we left Dundee, the vessel was in a tight, proper, and seaworthy condition. Nothing particular on the passage until the morning of the 13th September. Smoke was first seen on Saturday, 13th September, at 8.15 a.m. I was coming out at the cabin door after breakfast, the steward told me there was smoke coming out of the after-hatch ventilation, and I told him to tell the captain. The first thing the captain did, he went down the ventilator himself, ordered all the combustible stores to be removed, then battened tight down. In the afternoon I was sent to feel the hatches whether they were heated, and found them all cool, and in the dogwatch the captain ordered me to take off the cover of one of the ventilators on the poop. I took it off and kept it off until the captain told me to batten down again. During my first watch on deck I frequently felt the ventilators and hatches to see if they were getting heated, but found everything cool. At about 8 p.m., on Saturday the 13th, the men came aft and asked the captain to bear up for the vessel that was in sight. The captain answered that he had already done so. At midnight I was relieved by the second mate, and laid down in the after cabin, and about 3 a.m. (Sunday) I was awoke by a fearful explosion and rushed on deck, where I met the captain on the break of the poop; he was then giving orders to get the pumps and buckets under way. I went down on the main deck and looked after the work, set the men at the fire engine, force pump, and buckets. At about 4 a.m. the captain came on the main deck, and had a rope made fast round him and another small one in his hand, and went down each of the hatches, but had to come up soon on account of the smell of the gas, and when he returned he was almost exhausted. After the captain, I went down myself and could feel the heat of the coals in the main hatch, about 6 feet from the kelson. The captain ordered the carpenter to cut holes in the deck, to get the water down the better. Then at daylight on Sunday, 14th, we sighted a barque down to leeward; bore down to her, and proved to be the American barque "Taria Topan." Captain Broom hailed him and asked where he was bound to; he answered Mauritius; told him the ship was on fire and asked him to see him into the Cape. The captain of the "Taria Topan" said it was out of his course, but he would come on board. I was sent away in the boat for him; brought him on board; whilst on deck, and about to return on board his own ship, the men came aft and asked Captain Broom to steer for the nearest land, and asked the captain of the "Taria Topan" whether he intended to stay by them, as they said they could work with greater will. He told them he had agreed to do so. I swear that Captain Broom did all in his power to encourage the men and save the ship, but to no avail. When we started the boats at 3 p.m., the flames came up the chain pipes; the fire was spreading rapidly, notwithstanding the exertion of all hands at the pumps. The captain signalled the "Taria Topan" to close with him, and that he could do no more. About 6 p.m. the captain and myself left the "St. Mungo;" the flames were coming up all the hatches and spreading very fast; went on board the "Taria Topan." At night, about 10.30 p.m., the captain of the "Taria Topan" squared away; the "St. Mungo" presented one mass of flames. I wish to return our grateful thanks to Captain Hathorne, his officers and men, for the good treatment we all received whilst on board his vessel.

Alexander Scott sworn :

30 years old; born at Dundee. Has been 18 years to sea. Has been 15 months as officer. Has been two months and a few days on board the ship "St. Mungo." I joined the "St. Mungo" after the cargo was on board. I was at the fore part of the after hatch when the smoke was seen. The steward was the first to see the smoke. The steward and I came aft, and the captain at the time coming out of the cabin door, we told him about the smoke. The first thing the captain did, he went down himself with the seaman William Robertson, to examine if there was any fire or heat to be found, but could not feel any. The captain ordered the stores to be removed on deck and hatches battened down. Everything was covered up. At 3 a.m. on Sunday, 14th, I was on the poop and heard an explosion in the main hatch, and I called all hands; captain came out and ordered all the hands to get the fire engine, force pump, and buckets ready, and commenced to throw water, pumping as hard as we were able, but found the fire gaining on us. At 5 a.m. I went aloft and looked for a vessel, and another man went up the mizzen rigging reported a vessel on the starboard quarter. The captain gave orders to square away down on her, which proved to be the American barque "Taria Topan," bound to the Mauritius. The captain spoke the vessel and reported to be on fire. Asked the captain to come on board which he did, and proposed staying by us to try to fetch the vessel to the nearest port, then the captain of the American barque returned to his vessel. The fire was gaining on us, and towards noon could hardly see on account of the smoke. The lower deck and the tank casing were on fire. We tried our best to extinguish the fire, but uselessly. The captain encouraged us, and did all in his power to save the ship. At about 4 p.m. the captain gave orders to haul the main sail and cross-jack up; the fire smoke being severe on our eyes, could not stop to obey the order. The captain gave orders to clear away the boats. The "Taria Topan" shortened sail and laid close to us to receive us on board. The captain ordered me in the first boat, with a note to the captain of the "Taria Topan" to tell him we could not stay longer, the fire was gaining so rapidly on us. The four boys, three men, and myself were ordered to go on board the "Taria Topan." Got alongside the vessel, put the boys on board and ship's chronometer, came back to our vessel to render any more assistance, brought back some provisions on board the "Taria Topan." Got orders to come back for a third trip; came alongside; flames were bursting out of the hatches. The long boat was sent away with part crew and provisions, but on account of the heavy sea and wind freshening, the captain gave me the orders to take the long boat in tow, but did not succeed on account of the heavy swell; got alongside the "Taria Topan," hooked our boat on to the hatches, took her on board, came on the poop of the "Taria Topan," discovered the flames flying up the mast and the rigging of the "St. Mungo;" it was 6 p.m. The "Taria Topan's" boat went back and fetched Captain Broom and the mate on board. After 10 p.m., the ship being in a mass of flames, took the glass; could only discern the mizzen mast standing and flames running out towards

the bowsprit, and afterwards the "Taria Topan" squared away. We were well treated on board the American barque "Taria Topan," and I return my sincere thanks for the same.

William Ross, steward, George Wilkie, carpenter, Charles Reilly, A.B., John Miller, A.B., all on oath.

Swore to the correctness of the captain's entry in the official log-book, which was read to them, and on their being asked whether they were kindly treated on board the American barque "Taria Topan," they all said that they wished to express their gratefulness at the manner in which they were treated on board the said vessel.

Upon their being asked whether the captain and officers of their ship did everything in their power to save the vessel, they all answered in the affirmative.

Captain W. H. Hathorne was called in:

I am the master of the American barque "Taria Topan" of Salem, Mass. At 5.30 a.m., on Sunday, the 14th September ultimo, I sighted the ship "St. Mungo" with signals of distress. I bore down upon her; went on board and found that the vessel was on fire. Agreed with the captain of the ship to remain by the vessel until such time as my assistance will be needed, but found, in spite of the efforts of the captain, officers, and men of the ship "St. Mungo," that the vessel could not be saved. I returned to my vessel. About 10.30 p.m., the ship "St Mungo" presented a mass of flames, the whole of the crew having come on board the "Taria Topan," (31 in all,) I continued my route to Mauritius, the port I was bound to, and arrived on Friday, the 17th October instant.

The Board thanked Captain W. H. Hathorne for his conduct on the occasion, and promised that he will be favourably mentioned in their Report to the Board of Trade.

Report.

The "Saint Mungo," of 1,375 tons register, was built of iron, under special superintendence, at Hull in 1865, and classed at Lloyds A1, 20 years. Her length was 223, breadth 36.5, depth 23.4; owned by Messrs. Gilmour, Rankin, & Co. of Glasgow; registered at the same port, and commanded by Mr. Frederick Broom, who holds a certificate of competency as master, No. 26,933. At the time of her abandonment she was on a voyage from Dundee to Point de Galle, with a cargo of 1,800 tons of coals. Her crew consisted of thirty hands, all told.

On Wednesday, the 9th July, at 5 p.m., she left the Tay, her voyage being prosperous up to Saturday, September the 13th, when, at 8.15 a.m., the steward, William Ross, saw smoke coming out of the after ventilator, and reported the same to the master, who was then at breakfast; he immediately went on deck and saw a slight issue of smoke from the whole of the ventilators, there being nine in number. He then ordered the combustible stores, such as tar, varnish, oil, &c., that were below, to be brought on deck; he, in the meantime, went below, accompanied by one of the crew, to see if he could discover the position of the fire, but the smell of the gas was so intense that they had great difficulty in regaining the deck. The captain and chief officer then went down the main hatch ventilator in the lower hold to see if the fire was on the skin, but found everything cool from the keelson up to about 6 feet; they concluded from this inspection that the fire was in the body of the vessel. The hatches and other openings were then ordered to be securely battened down, in hopes of smothering the fire, and after a time, the deck and hatches appearing cool, one of the ventilators was opened to allow the foul air, if any, to escape. After this precaution, the captain thought there was no fear of an explosion. At midnight there was no appearance of fire, but at 3 a.m., the fore, main, and after hatches blew off with a terrific explosion, the flame at the same time extending half-way up the mainmast, and dense volumes of smoke issuing from the whole of the hatches; immediately all hands were set to work drawing water and pumping with both force pumps down the main hatch; holes were also cut in the deck to allow the water to be poured freely over the burning cargo. At this critical time a vessel was sighted to leeward. The "St. Mungo" was then kept away and bore down on her. She proved to be the American barque "Taria Topan" from Boston, U.S., bound to this port with a general cargo. She was hailed and requested to remain by them, which the American captain readily promised to do. He then went on board the "Saint Mungo" and saw the exact state of the vessel. They agreed upon signals in case of immediate need, the captain still hoping to get his vessel into the Cape of Good Hope. The crew promised to do all in their power if the American barque would remain by them. Every exertion was made during the day to get the fire under, but without success. At 3 p.m. the fire burnt through the deck and rapidly spread over the vessel. Seeing that it was necessary for the preservation of life to abandon the vessel, the "Taria Topan" was then signalled to come near; the boats were then lowered and the vessel finally abandoned in lat. 35° 5′ S., long. 20° 40′ W. Table Bay, Cape of Good Hope, then bearing E. by N. ½ N., distance 2,060 miles. When the boats were in the act of leaving the ill-fated "Saint Mungo" a large ship passed close to but did not take the slightest notice of them, but held on her course to the S.E. Two days after the ship "A. L. Louis" of London, was spoken and told by Captain Hathorne that he had 30 men, the crew of an English ship, on board, and requested that as his vessel was small and having a long passage before him, that he would relieve him of part of the crew. In reply he cooly told him to put into the Cape and land them. It is unfortunately but too true that vessels in distress are frequently passed unnoticed by those in good condition.

Although it would appear, from the number of ventilators, that this ship was well and properly ventilated, but in reality she was not, as only three of the ventilators went to the bottom of the vessel, the others simply ventilating the between decks. The proper way to ventilate a vessel for coal is to have horizontal ventilators, running the length of the vessel under the between deck beams, and on the skin in the lower hold; those ventilators should be attached to the perpendicular ventilators from the deck. There can be no doubt that the explosion was due to the inflammable gases which had been accumulating among the coals and which the ventilators were unable to remove.

The Board, after hearing the evidence of the witnesses, which being the same in every respect, and was corroborated by Captain Hathorne, is of opinion that the abandonment of the "Saint Mungo" was necessary, and that the master, officers, and crew only adopted that measure when all chance of saving the property entrusted to their charge was entirely done away with; that no blame whatsoever can be attached to them, and have therefore much pleasure in returning the captain, chief, and second officers their certificates.

It now becomes the duty of the Board of recording the generous and hospitable treatment received by the master, officers, and crew of the "St. Mungo" from Captain W. H. Hathorne, of the American barque "Taria Topan" to whom honourable and ample testimony was borne. This is the second time in less than five weeks that British seamen have been rescued and brought to this port when in distress by vessels of other nations, the Board ventures to hope that the manly, honourable, and meritorious conduct of Captain William Hollingsworth Hathorne will meet with the favourable consideration of the Board of Trade.

Of the ship "Beechardass Ambaidass."

"WAVERLEY," of Liverpool, of 999 tons register.

Inquiry held at Singapore, this 16th day of October 1873, into the loss of the British ship "Waverley," of Liverpool, official No. 45,453, 999$\frac{7}{10}$ tons burthen, bound from Shields to Singapore with a full cargo of coals, before the Hon. J. W. W. Birch, Police Magistrate, and Messrs. E. M. Smith and H. Ellis, Nautical Assessors.

Robert Calvert sworn, states:

I was master of the late British ship "Waverley," official No. 45,453. I left Shields on Friday, 27th June 1873, with a full cargo of coals, bound to Singapore. We proceeded all well until the 16th September, when we sighted the island of St. Paul's. On the following day we got a strong smell of gas. On examining we found neither smoke nor fire down below, but which we thought was caused by want of ventilation. On the 18th September, after removing the coals from the hatchway we found the smoke coming up, an explosion took place. We tried to put out the fire by battening down the hatches. The hatches were blown right off every two hours, and we found it impossible to batten them down. About 10 p.m. on the same day an explosion took place and blew the hatches up, and the flames reached nearly to the masthead; after which we hove to, put the boats out, and put provisions in them. On the following morning after daylight vast volumes of smoke issued from all hatchways, and we considered it time to leave the ship. We remained by her till she sunk the next morning, about 2 o'clock. We remained till sunset, when we were picked up by "President Van Ryckevorsel." I think the leaden pipes of the force pump got melted, and the water must have come in. On the 17th of September our position was, latitude 38° 23′ South and longitude 81° 37′ East; on 18th, latitude 38° 6′ South, and longitude 86° 45′ East; and on 19th, latitude 37° 39′ South, and longitude 88° 7′ East. On Saturday, the day we were picked up, our position was, latitude 37° 44′ South, and longitude 89° 34′ East. Our cargo was West Hartley coals. I had nothing whatever but coals which could have caused an explosion. When we left the ship it was blowing a strong breeze from north-west. Everything was quite correct three weeks before, when I had occasion to trim the coals. A fire occurred in the centre compartment, and it was impossible to get down here, as the coals were choked full to the top.

R. Calvert,
Master, late ship "Waverley."

Before us,
J. W. W. Birch, President,
Police Magistrate.
E. M. Smith,
H. Ellis, } Nautical Assessors.

William Cole sworn, states:

I was mate of the late ship "Waverley." I hold a certificate of competency as master, No. 5,032, from the Board of Trade. I lost my certificate in the ship. The vessel was lost. On 17th September we perceived a slight smell of gas. On the 18th we discovered smoke coming up the ventilators. On the night of the 17th all was shut up; the water in the tanks was quite cool. About 10 a.m., 18th September, an explosion took place. I never saw explosions of that sort before. We got provisions on deck and secured the hatches. On the evening of the 18th, about 10 o'clock, a heavy explosion took place and blew the hatches off. We got the boats off, and at daylight on the 19th, at 5.30, we left the ship. The vessel went down about 2 o'clock on the morning of the 20th. I think the melting of the pipes and brass around must have caused the vessel to go down so soon. I lost my log-book. I believe the ship's papers were saved. The fire broke out in the centre compartment. It was impossible to get down there, as the coals were up to the beams. We did pour water down on the main hatch, but gave it up as useless. I never saw explosions like this before. The explosions were accompanied by a noise like a steam whistle. All hands were saved. We were to the eastward of St. Paul's about 500 miles.

Wm. Cole,
First Mate, late ship "Waverley."

Before us,
J. W. W. Birch, President,
Police Magistrate.
E. M. Smith,
H. Ellis, } Nautical Assessors.

Patrick Miagha sworn, states:

I was second mate of the "Waverley." I have a certificate from the Board of Trade, No. 93,771, which I now produce. I recollect the day the gas commenced to escape, viz., on Wednesday, 17th September. We thought it might be foul air. At 6 a.m. the next morning we discovered the fire. Smoke was seen issuing from the ventilators, which I at once reported to the captain. I received orders to go down amongst the coals. I went to all parts of the ship I could get into, but found no signs of fire. In the afternoon we set to work to get provisions on deck, in order to batten down the hatches, thereby putting out the fire. We were prevented by the explosion, which blew off the hatches. We got the boats out during the night of the 18th, and at 5.30 a.m. on the 19th we took to the boats, but hung on to the ship. The vessel was hove to before we got the boats out. She was all in a flame; the masts fell, and she went down about two hours before daylight. A few hours before she went down the boats got parted. There was a heavy sea on. We were picked up the next evening. We poured water down the main hatch, but it did no good. The ventilators were taken down and the opening for them stopped up. At the latter part of the 18th the explosions became very frequent, and it was impossible to keep the hatches down. The explosion was something like the noise of steam passing through the safety valves. We sounded the pumps regularly all the way. I never saw the pumps used during the time I was in her. All was done to save the ship that could be done.

Patrick Miagha,
Second Officer, late ship "Waverley."

Before us,
J. W. W. Birch, President,
Police Magistrate.
E. M. Smith,
H. Ellis, } Nautical Assessors.

Robert Philip sworn, states:

I was carpenter of the "Waverley." I recollect the day she was lost. We first noticed the smoke issuing out of the ventilators. I examined it, but there was no sign of fire. I saw smoke coming out of the quarter hatch. The flame first showed itself that night at 10 p.m. I did sound the pumps, She did not make any water. The water in the tank was quite cool. The smoke came out of the after part of the main hatch. The hatches were battened down, but they were blown off by explosions. The explosions were not very strong. The one that went up the mainmast was like a rocket. I have been four years at sea. Everything was done to save the ship that could be done.

Robert Philip,
Carpenter, late ship "Waverley."

Before us,
J. W. W. Birch, President,
Police Magistrate.
E. M. Smith,
H. Ellis, } Nautical Assessors.

Hugh Hughes sworn, states:

I was boatswain of the late ship "Waverley." I recollect when the ship caught fire. We discovered the fire when we went down the after hatch. We got a slight smell of gas. The smoke was coming out from the centre compartment. After the smoke cleared away I went down, but did not go far, as the coal was chocked up to the beam. We put the hatches on, trying to smother the fire, but the explosions blew the hatches off. We had done all we could. We put some water down the after hatch, but it did not do much good. We left the ship at daybreak. It was not safe to stand by her any longer. The vessel burnt up, and in the morning we could not find her.

Questioned by the Master.

When I and some men went down to clear away the coals the smoke issued out. I did not stop there long.

Hugh Hughes,
Boatswain, late ship "Waverley."

Before us,
J. W. W. Birch, President,
Police Magistrate.
E. M. Smith,
H. Ellis, } Nautical Assessors.

We the undersigned seamen of the late ship "Waverley" consider that the burning of the ship was purely accidental, and everything was done that could be done.

Decision.

The Court having inquired into the loss of the British ship "Waverley," of Liverpool, official number 45,453, finds that she was destroyed by fire at sea in or near lat. 37° 39′ S., long. 88° 7′ E.; that she foundered, and that all hands were saved. The Court considers that it would probably have been wiser to have used water a little more freely than appears to have been done; but looking to the weather and the situation of the ship so far from land, and to the constant explosions, they consider that no blame can properly attach to the master, and they are of opinion that his certificate should be returned to him, as well as to the first and second mates.

J. W. W. Birch, President,
Colonial Secretary and Police Magistrate.

Singapore, 16th October 1873.

"HERBERT GRAHAM," of Newport, Mon., wooden ship, of 337 tons register, six years old, classed A1, 13 years.

Town Hall, Newport, Tuesday, January 6th, 1874.
Coram:
Nelson Hewitson, Esq., Mayor,
Thomas Beynon, Esq.
Assisted by—
Captain H. Harris, }
W. Parker, Engineer, } Assessors.
Mr. Darley, Shipwright, }

Mr. Hamel appeared for the Board of Trade to conduct the case.

Inquiry as to the loss of the barque "Herbert Graham." Mr. Hamel opened the case.

Evan Roberts sworn, states:

I was late master of the "Herbert Graham," and held a certificate of competency as master, which certificate I lost during my travels in Patagonia. I joined the "Herbert Graham" on the 1st day of July last. She was laden, and ready to go out. We had a crew 10, all told. We had 536 tons of coal on board, and were bound for Valparaiso. I went into the hold several times on the voyage. In fore hold there was a large space between the coals and the deck, about 7 or 8 feet; the after hold was full. I never saw the vessel empty. We had a half-poop on deck rising 3 or 4 feet; the cabin occupied the whole of the poop. We ventilated the ship by means of the after and fore hatchways. These were continually kept open except in bad weather. The hatchways were, I think, about 8 by 6. We had fine weather all the voyage except for about 12 days off the River Plate, in the beginning of September. It was windy weather, which obliged us to close our hatches; so much water was going over that we were bound to close them. No complaints were made till the 19th of September by the crew of the gas. On that morning at eight bells the mate told me the watch had not come on deck. I went forward and saw three men lying on the forecastle floor unconscious. I could not get a word out of them. They had a stove fire in the forecastle at this time; it was cold weather. I got a rope and made it fast to the three men, and pulled up one at a time on to the deck and in about 20 minutes they came right and then they told me the forecastle was full of sulphur. I ordered the men to leave the forecastle, extinguish the fire, and clean it out. I sent them to a house in the break of the poop. The hatches fore and aft were open at this time. The men would not live in the house; it was too cold, they said, and they returned to the forecastle. This was the next day. I let them go. I heard no complaints. After that the forecastle was nicely cleared up, and they lighted the fire again. Nothing occurred till the 22nd of September. At 6 p.m. they reported (that is, one of the seamen did) that smoke was coming out of the fore hatch. Myself and the mate went to see what was the smoke, and we found very little, but ordered the hatches fore and aft to be battened down close; that was done, and in about an hour, more or less, they were opened again. When they were opened a second time the vessel was full of smoke, which cleared away in about 10 minutes. I went below to examine the hold, and found that the cargo of coal was on fire right amidships. I went on deck and ordered the vessel to be battened down close again, and changed the ship's course for the land. Smoke was escaping through the night from the tarpaulins on the hatchways, and the fore companion. Next morning my men were very anxious, and wanted me to put out the boats. At daylight in the morning (23 September) we erected two big davits, one on each quarter, to support the boats. It was not safe to leave them on the hatchways. They were put into the davits ready for lowering. In the morning continually the smoke was coming out from under the tarpaulins over the hatchways, and the deck was getting hot. At 9 a.m. we sighted the land, Port Santa Cruz, bearing W.N.W., distance about 35 miles. All sail, except the two royals, were set, and we were making for the land. At about 10 a.m. it became calm; then she had no way. It was a very fine day. I consulted with the mate, and we thought the best thing to do was to open the hatchways and discharge a part of the cargo. We opened them between 11 and 12 to see if we could extinguish the fire. When we did so, we found the vessel was full of smoke; we could hardly breathe in it on deck. There was a smell of timber burning in the hold. The smoke all cleared away in about 10 or 15 minutes, when the fire burst out from the fore and main hatch. The boats were at once lowered, and the men went into them, except the mate, boatswain, and myself. We remained on her poop for about an hour and a half. We were looking at the flames coming up. I went on the main deck once or twice, and the pitch was boiling out of the seams, so that I could not remain there. The men remained in the boats by the ship. We three got in at about half-past 1 or 2 o'clock of the 23rd. When we left the ship the flames were ascending 4 or 5 feet above the main hatch. I did not go on board again. We saved most part of our clothes and effects, and the log books, but we lost them, the men left them in the long boat. We did not remain. The wind came off the land in the afternoon. We pulled for the land, and I saw her masts, fore and main, come down at about 5 o'clock that afternoon. She burnt up till 3 o'clock of the morning of the 24th September, and then disappeared. The ship on the voyage was very tight, made very little water, and was pumped out morning and evening in two or three minutes. We landed on the 26t about 25 miles N.W. of Cape Virgin on the coast of Patagonia. In landing one man fell overboard into the surf from the long boat. We picked him up again, but he afterwards died from the cold and exposure. His name was John Rowley, able seaman, a native of Quebec. We buried him on the beach under a cliff: he was a healthy man. We proceeded in the boats about 54 miles by the shore, and on the morning of the 6th of October a large steamer passed us. We signalled to her; she took no notice. I could see people on the deck. I don't know whether they saw us. It was about 9 o'clock in the morning. Seeing our provisions were getting short we started overland to Sandy Point. We started nine in number till we came to a river; five of us crossed, and the other four said they would go back to the boats; they went; I waited two hours; they would not come with us. In six days we reached Sandy Point, walking most of that time. We met some natives about a mile from that place. We were very kindly treated by the Governor of that place. We had nothing but water the last three days of our journey; previously we had six biscuits each. From Wednesday till Sunday, the 12th, we had no food. We left there on the following Tuesday in one of the Royal Pacific Mail Steamboats for Valparaiso, and from there we were sent to Liverpool in another steamer. I can give no opinion as to the cause of the fire.

(*By Mr. Graham.*) We had two chronometers on board.

[The Court decided that Mr. Graham had no *locus standi.*]

(*By Captain Harris.*) There never was much water in her.

(*By Mr. Darley.*) We had first-class iron pumps; 9 inches of water in the well; the delivery pump about 6 inches, fitted with breaks. We had double breaks but never fitted them, as we never had occasion to do so. We first discovered the fire under the main hatchway. I could not find the particular spot of the fire. I could not bear my hand in the coals 6 inches down on the 22nd September. We had no ventilation but the after and fore hatches. The ship was in fine trim, draught 16 aft and 15 forward.

Evan Roberts.

George Farrer sworn:

I was mate of the "Herbert Graham." I hold a certificate of competency as mate. I joined her on the 1st of July, same day as the captain, the day she left. Her cargo was in. On the Friday before we saw the smoke the men complained of gas. We had been 81 days at sea; the weather was very hot. On the 19th September saw the men lying on the forecastle floor, and I helped to pull them up; they were all right in about 20 minutes. I saw the smoke coming from the hatches we battened down. I went with the captain to inspect; we found the cargo very hot. We dug in as far as we could with our arms; we felt it the hottest about midships, where was the bulk of the cargo. The hatches were battened down till the day after we saw the smoke. At about midday the smoke overpowered us; shortly after the flames broke out. We lowered the boat and prepared to get to land, finding we could do no good. I and three others left the captain at the river; we returned to our boats, and seeing a steamer, the "Cuzco," we pulled to her. She took us on board, waited for us about half an hour, and landed us at Liverpool. I never smelled any gas from the coal. I could not smell sulphur. In the hold the smell caught our breath. It was the smell like the burning of oak timber. During the voyage we put no water down. We did not use shovels.

(*By Mr. Darley.*) When we first saw the smoke we did not think the coal was on fire. Our vessel had about 5 feet freeboard. Our pumps were fixed in.

G. Farrer.

William Roberts sworn:

I was an able seaman on board the "Herbert Graham." I joined her two or three days before she sailed. She was in the river at Newport. Cargo in. I lived in the forecastle. I was on deck and saw the men lying in the forecastle. Me and the captain went down. Smelt of gas; it made me sick. I could not stay long there. We got the men upon deck and cleared out clean of the forecastle. We returned to the forecastle, but did not smell the gas again till she caught fire. I thought it was the smell from the store. It was like a smell of sulphur; we could not remain in the forecastle. On Sunday night when the flames came up we left the forecastle, about 8.30, and battened everything down. We had to take to the boats.

(*By Captain Harris.*) The stove we had in the forecastle had a funnel through the deck.

his
William × Roberts
mark.

William James sworn:

I was formerly master of the "Herbert Graham," and was formerly part owner of her. I joined her as master when she was on the stocks in the builder's yard at Scilly. She was on the stocks built when we bought her. On the 1st of July, the day she sailed, I gave up the command to Captain Roberts. I was by her when she was being loaded. She had discharged a cargo of iron ore from Spain. On the 20th of June, I took in stiffening about 70 tons, finishing on the 23rd June. This was in the lower Newport dock. We then went to the upper and took in the remainder of the cargo of coal. We were loading two days, Wednesday and Thursday. I told the trimmers to leave a space aft and forward, but fill her up midships at the main hatch. She left her loading berth on Friday, and we hauled her down to the lower dock again, near the lock. She remained there. I took-in stores. I hauled her out into the lock of the dock on the 1st July, and then gave up the command. I had a cargo of coal on board this vessel once before. I weighed out then 139 tons in Japan. I had the same ventilation then as afterwards—the hatches; that is the only ventilation we had.

(*By Mr. Beynon.*) I think it was raining when we took in the stiffening. I never remember any cargo of house coals shipped at Newport taking fire before.

(*By the Mayor.*) With steam coal it is usual to have shutes as a means of ventilation, but this coal on board the "Herbert Graham" was house coal.

(*By Mr. Darley.*) I think the shutes are quite useless as ventilators. The "Herbert Graham" was insured for 4,000*l*. I value her at 4,800*l*. She was classed 13 years at Lloyds. No force pump was on board.

(*By Mr. Parker.*) We had no provision on board for extinguishing fire.

Wm. James.

Thomas Edwards sworn, states:

I am a shipbuilder of St. Mary, Scilly. The "Herbert Graham" was built in my yard under a special survey of Lloyds. She was classed A1, 13 years. She was built of English oak frame and upper deck beams. Main keel English elm. I built her as a merchant vessel to carry cargo. She had three hatches on the main deck, air courses fore and aft, and under the hold beams was the ventilation. No ventilation shaft to the ship.

(*By Captain Harris.*) We always put chocks between the frames, but they are taken out before the vessel is planked.

(*By Mr. Darley.*) The ventilation is to prevent dry rot, and not for ventilating a cargo of coals. It was understood by Lloyds surveyor that the "Herbert Graham" was being built for a general cargo. All vessels that I have built generally take coal as a first cargo. I never heard of one taking fire before. Lloyds surveyor never called my attention to the importance of ventilation in the ship. I never heard of a valve or a cock to plug the vessel if required in the event of fire. I would recommend such a pipe to be fitted under water.

Thomas Edwards.

James Barber sworn, states:

I am foreman coal-shipper under Messrs. Webb, Spittle, and Bladon. They supplied the coal to the "Herbert Graham." I superintended the shipping of the coal. I saw the stiffening put in. The loading of that began on the Saturday. It was put in in the old dock, laden in the open, not under cover; it was brought in trucks. We put about 10 trucks (50 or 60 tons) on the Saturday, seven trucks being left; they stood outside. It rained on the Saturday while the stiffening was being put on board, and it rained up till midnight on the Saturday night. The men knocked off work because of the rain. On Monday morning it was dry, and the men got to work again, and put in the seven trucks that had been left out. Then the ship went to the other dock to take in the remainder of her cargo. I superintended the shipping of that. The cargo was dry. It came direct from the colliery in trucks. The first lot came on Monday morning, and more coal arrived till she was filled up; it was perfectly dry weather while she was loading her cargo. I was in the hold twice or three times while she was loading; I was not in the hold after the cargo was completed. The coal shipped was of three different qualities. The stiffening was all brush coal; it came principally from the Mamhole Colliery; brush coal is next to large in quality. Small coal came from Coalbrooke Vale and some from Cwmserchan. The large coal was from Cwm Colliery at Aberbeeg. I can tell the coal one from each other on seeing them. The two pieces produced are Cwm Coal. This piece is the Crumlin coal from Pant Glas Colliery. Most of the coal put on board was brush coal. I do not know the quantity of Cwm coal put on board. The piece of coal now produced with a stain upon it is Crumlin coal from a lower vein from that we work at present. The customers did not like the stain in it, and therefore, we work the other. The stiffening was a mixture of small and round coal.

James Barber.

Patrick Donovan sworn, states:

I am a coal trimmer. I trimmed the coals on board the "Herbert Graham," and helped to stow them; the coal was dry and I could see no fault in it. It was fine as we loaded, could not be finer. I trimmed her all right. She was full in the main hatch and after hatch, but not forward. I was not present when the stiffening was put in.

his
Patrick × Donovan.
mark.

William Kirton Quest sworn, states:

I am deputy dockmaster of the Newport Dock Company. We keep a record of the wind, &c. The weather was fine during the last week of June and up to the 3rd of July. I know it was raining when they took in the stiffening of the "Herbert Graham." I was going past, and the tarpaulins not being properly placed to prevent coal falling into the dock, I complained to them about it, and I distinctly remember it was raining hard at the time. When she left the locks she was reported 16 feet draught of water.

W. K. Quest.

Adolph Pierre Vassard sworn, states:

I am a consulting chemist in London. I have had submitted to me some samples of coal similar to that carried by the "Herbert Graham," and I have analysed them. The result of my analysis is contained in the written report produced.

Report read as follows:—

Re "Herbert Graham."

A sample of the coal carried by this ship at the time she was burnt sent to me under the seal of "Searchers Customs, Newport," has been analysed and otherwise examined by me according to instructions. I found the coal highly pyriteous and very brittle.

It contains per 100 parts—

Moisture	0·35
Hydrogen and nitrogen	9·10
Carbon	81·00
Mineral ash	5·40
Iron pyrites	3·04
Divers and loss	1·11
	100·00

Though the sample I received was in three lumps, I am warranted, considering the general practice of the coal trade with the Pacific Coast and the brittleness of the coal under examination, to say that it was shipped small, or became such by the loading. Small coal absorbs easily any amount of moisture.

The quantity of iron pyrites is very large. Iron pyrites are a bisulphuret of iron, that is to say, a compound of iron and sulphur. Over three per cent. of iron pyrites, as shown by analysis, would give, if allowed to naturally decompose, nearly one per cent. of free sulphur. To the presence of so large a quantity of pyrites I attribute the burning of the 'Herbert Graham."

When bisulphuret of iron or iron pyrites is left when wet to the action of the air, or to the action of a moist atmosphere, it gradually undergoes a chemical change; one part of the sulphur is oxidised partly by the *oxygen* of the air and partly by *that* of the decomposing *water*, and becomes *sulphuric acid.* Thereby the other part of the sulphur is disengaged from the pyrites, and also hydrogen from the water. This sulphur and the then free hydrogen are thus thrown in presence of each other, combine, and form *hydrosulphuric acid* or *sulphuretted hydrogen.*

These chemical reactions produce a great heat, whereby the sulphuretted hydrogen is ignited and therefore oxidised, producing *sulphurous acid* and *free sulphur,* which is also ultimately burned.

It may then be easily understood that if a combustible material like coal, disengaging already inflammable gases through its continually going on decay, is found mixed with the chemical bodies producing the above reactions and effects, this combustible will be heated and ultimately ignited.

Such is the chemical explanation of what is called "spontaneous combustion," and of what undoubtedly took place in the hold of the "Herbert Graham."

If the coal had been shipped completely dry, and so kept all the while, no spontaneous combustion could happen.

A. VASSARD.

I was present in court during the examination of the witnesses, and I heard Mr. Barber, the foreman coal shipper, state the different kinds of coal shipped on board the "Herbert Graham." I have no doubt that the stiffening about 70 tons of coal put in during wet weather would moisten the whole cargo in any circumstances; in three or four days it would moisten the cargo. It further appears that the whole of the cargo was shipped direct from the colliery, and would contain a large quantity of moisture, more than three per cent. It is the same with all coal except large coal. Three per cent. of water would be sufficient in time to ignite the cargo if the coal remained in bulk undisturbed, and would ultimately take fire. There is no danger with large coal, but with small coal there is. I think the chemical composition of the coal explains the fire on board the "Herbert Graham." About half a ton of sulphur would produce a sufficient quantity of sulphurous acid to extinguish a fire in 1,000 tons of coal on board ship. To apply this a pipe would have to be fitted to the ship and carried under the cargo. I would have a small stove on deck, and when a fire has been lighted in it throw sulphur on the fire. Sulphurous acid would then arise and be carried down the pipe attached to the stove into the vessel's hold. In five or ten minutes that would extinguish the fire. Even if the pipe was containing a little water the acid would still escape. It would not be necessary to have the hatches down when the process is going on. The sulphurous acid is twice as heavy as air. A small air pump might be necessary to force the sulphurous acid through the water covering the pipe. The acid would not be dangerous to life, through being oxidised before reaching the deck. I doubt whether ventilating the cargo with shafts when loading would have any effect unless the coal was shipped perfectly dry. I don't think the shafts are of any use except to prevent the explosion of gas. If water was used to extinguish the fire, the cargo would have to be covered all at once; a small quantity would be of no use; this would facilitate combustion. Captains of ships ought to be provided with thermometers, and when they find the coal is heating the application of sulphurous acid would check further combustion. The sulphuretted hydrogen produced by the decomposition of the pyrites would ignite between 170° and 173° Fahr. The ordinary temperature even down to freezing point is sufficient to make the pyrites decompose, providing water and air be present. I mixed the whole five samples of coal from the "Herbert Graham" together, and on analysis found the mixture contained over three per cent. of pyrites. I should not be surprised if one of the samples contained as much as 10 per cent. of pyrites. I do not think washing the coal would have prevented ignition. The washing of coal is based on the difference of specific gravity between iron pyrites and coal, and can only be applied to small coal. I never saw it done. I never heard of it till lately. The pyrites will take fire sooner if the temperature is warm.

By Mr. Darley.—Can you explain why the introduction of wood trunks and louvre boards amidships placed against the stanchions and other means of ventilation produce a good effect,—produce a good effect in one case and are injurious in another?

Answer.—All depends on the nature of the coal; with coal containing no pyrites, therefore not liable to spontaneously ignite, ventilation has a good effect in carrying away the gas, but the contrary is the case with coal containing pyrites, and therefore liable to spontaneous combustion. In the last case a good reason can only be possible if the coal is shipped dry and so kept all the voyage. I think testing tubes should be fitted to ascertain the temperature of the coal, which should be ascertained every day. I think if testing tubes had been fitted on board the "Herbert Graham," they might have ascertained the existence of fire earlier and discharged the cargo. Testing tubes could not be used to send the gas down. It would be better that coals should not be shipped direct from the pit; but this would be quite impossible.

A. VASSARD.

Report.

Report of a Court of Inquiry held at the Town Hall in Newport, Monmouthshire, by order of the Board of Trade, before Nelson Hewertson, Esq., Mayor, and Thomas Benyon, Esq., J.P., with Captain Harris as Nautical, and Messrs. Parker and Darley as Engineer and Shipwright Assessors, into the circumstances attending the burning of the barque "Herbert Graham," which occurred on the morning of the 24th day of September last, near the entrance of the Straits of Magellan.

The "Herbert Graham" was a barque, built of wood at St. Mary's Scilly, in the year 1869, and registered at this port in the same year, of the burden of $337\frac{60}{100}$ tons. She was owned by Robert Graham and others of this port, and on this present voyage was commanded by Mr. Evan Roberts, who held a certificate of competency as master, which was lost after the destruction of the ship. The "Herbert Graham" left Newport on the first of July 1873, manned by a crew of 10 hands all told. She was laden with a cargo of 536 tons of coal, bound for Valparaiso. Nothing worthy of remark occurred till the 19th of September, when three of the crew were found in the forecastle in a state of stupor. They were removed to the upper deck, when in about 20 minutes they recovered their senses, and stated that the forecastle was full of sulphur, which they attributed to the presence of a close stove which was allowed in the forecastle, the weather then being very cold. They were removed to a house aft, and the fire in the stove put out. The following day they returned to the forecastle, and no further complaints were heard. On the morning of the 22d smoke was discovered issuing from the fore hatch, which was battened down. In about an hour the hatch was taken off, and it was discovered that the ship was full of smoke, which, clearing off in about 10 minutes, enabled the master to go into the hold. Upon descending he found that the cargo was on fire amidships. All the hatches were closely battened down. and the ship's course directed towards the land. The following morning they sighted the land in the vicinity of Port Santa Cruz, but falling calm, after consultation it was decided to open the hatches and throw overboard part of the cargo, in the hopes of reaching the fire. In about 10 minutes after the hatches had been taken off flames burst up from both fore and main holds. In this state of things, and being powerless to control the flames, the crew were sent into the boats, the master, mate, and boatswain remaining on board till 2 p.m. of the 23rd, whan, for their own safety, they were obliged to abandon the vessel and pull towards the shore. At 3 a.m. on the following day they saw the vessel disappear. On the 26th they landed near Cape Virgin, on the coast of Patagonia. In landing one of the crew fell overboard from the effects of which and exposure on shore he died, and was there interred. From this they proceeded in their boats about 50 miles up the Straits of Magellan, but finding the wind against them, and their provisions getting low, they determined to walk to Sandy Point, a penal settlement of the Chilian Government. Five of the crew accomplished this after great suffering from exposure and hunger, and were kindly treated by the authorities at Sandy Point, who forwarded them home. The other four who separated from their companions preferred proceeding along the coast in their boat, and falling in with a passing steamer, were taken on board and conveyed to England. The captain and his crew seemed to have done all in their power, under the circumstances in which they were placed, and only abandoned the ship for the preservation of their lives. The main object of this inquiry was to ascertain the cause of this casualty, and, if possible, to devise some means of preventing similar accidents in future. From the evidence it would appear that five different descriptions of coal, taken from the vicinity of Newport, were shipped on board the "Herbert Graham." About 70 tons of this coal was put on board as ballast in rainy weather, and the vessel was removed to another dock to complete her cargo, during which time the weather was fine. These coals were brought direct from the colliery, and would therefore be more or less damp, according to the evidence of M. Vassard, who was examined as an expert on this inquiry. This gentleman analysed three samples of coal, similar to that forming part of the cargo of "Herbert Graham," and found that they contained three per cent. of iron pyrites, which would decompose through moisture and exposure to the atmosphere, and thus become sulphate of iron and sulphuretted hydrogen. This sulphuretted hydrogen, under the influence of the heat produced by the above reaction and the atmosphere, would ignite and cause spontaneous combustion. And these coals having been shipped in a moist state, and containing a large amount of pyrites, would, in his opinion, be alone sufficient to account for this casualty. With these facts before us, it becomes necessary, if possible, to seek some means of prevention. Several plans were discussed by means of ventilation on the one hand and of water on the other. It was found, however, upon investigation, that in accordance with the above hypothesis the introduction of either water or air would have a precisely opposite effect. It further appeared, from the evidence of M. Vassard, that if sulphurous acid could be circulated through the cargo it would prevent spontaneous ignition. This acid could be obtained by burning sulphur, 10 cwt. of which would be sufficient for a cargo of 1,000 tons of coal. It is a matter of after consideration how this may be applied, either on the principle of the fire annihilator or otherwise. This method seemed the most practical that was offered, and, in the opinion of the Court, might be usefully applied to vessels carrying coals and bound on distant voyages. In offering this opinion, however, the Court desire it to be understood that they do not consider the general question exhausted with reference to the preventing the recurrence of casualties of this description.

Given under our hands this 8th day of January 1874.

NELSON HEWERTSON,

Assessors.

"MINNIE GRAHAM," of Newport (Mon.), barque of 273 tons register, five years old.

Town Hall, Newport (Mon.),
Friday, March 13th, 1874.

Coram :

NELSON HEWERTSON, Esq., Mayor.
THOMAS BEYNON, Esq.

Assisted by :

Captain HARRIS, and } Nautical assessors.
FINTON WAKE, Esq. }

Inquiry directed by the Board of Trade as to the circumstances attending the abandonment of the "Minnie Graham."

Mr. Hamel appeared for the Board of Trade to conduct the case.

Case opened by him, and calls—

ROBERT BALE sworn, states :

I am a seaman, and shipped as boatswain acting second mate on board the "Minnie Graham." I shipped on the 16th July, and sailed the 17th from Newport. We had a crew of ten all told and a full cargo of coals. I noticed the coal was shipped wet. I saw a few trucks that was wet. It was mixed coal, large and small. We were bound for Valparaiso. We had two main pumps on board abaft the main mast. We had four small ventilators coming through the mooring post. They were cast iron and came through the covering board. I could get my arm into them. They went straight up and down, and could be plugged at the top. The plugs were out when it was fine weather and put in when it was rough. We had three good sized hatches, ordinary size; they were always off on the voyage when the weather permitted. Not the main hatch but the fore and aft ones. Always a wash of water across the main hatch; that was not so in fine weather. We never raised the main hatch in fine weather. We had a long boat shipped across the main hatch, and it was a good deal of trouble to get off. We had fine weather till we got off the Plate. She rolled easily. The wash I refer to came over the covering board. I believe the mate saved the log-book. Three or four days before we first saw smoke there was a strong smell of gas in the forecastle and also in the cabin. Nothing happened before this. We had an average voyage. The escape of gas was reported to the captain. He came to see what was the matter. He went into the forecabin and also in the hold. After that the hatches which had been opened were battened down. It was cold weather at the time. We were the other side of Cape Horn at the time. We were not in sight of land. Soon after the hatches were battened down we could not stay in the forecastle for smoke. The hatches were kept on till we saw the ship that took us off. It might be four days. The ship was the "Naval Reserve." We signalled her. She put out her boats, came alongside. Our boat was taken off the hatches after she boarded us. We had two boats. The small one was got out before the "Naval Reserve" boarded us. We had not provisioned the boats. The captain and carpenter of that ship came on board. They passed a survey on the ship and the main hatches were taken off. I dug away the coal under the main hatchway by direction of the two masters. We found the coal so hot just below the surface that I could hardly hold it in my hand. I dug down about two feet. Smoke was coming up as much as I could bear. The iron stanchions from the deck beam to the hold were hot, very hot; it was as much as I could do to hold them. The captain was down in the main hold and in the fore hold. I went into the fore hold and found the coals there just the same. I saw no fire. I poured in four or five buckets of water into the hole that I dug under the main hatch, but it would not penetrate, it stopped on the top. I did this to see if any steam would come up. Our captain, the captain of the "Naval Reserve," and the carpenter held a consultation (our mate was sick in bed), and they determined it was not safe to remain on board. We could not tell but what in any minute she might blow up. The ship was abandoned by us all. The carpenter of the "Naval Reserve" bored a hole just underneath the cabin deck to sink her. We were taken off in the "Naval Reserve" boats. I left in our own little boats; it was fine weather. I saved some of my clothes, just as much as I could scramble up. It was not safe to take a light below. It was in the evening when we left. Our long boat got stove. Our small boat was got on to the "Naval Reserve's" deck. It was fine weather, with whole sail breeze. I don't know how the wind was. She had not gone down about 10 o'clock that night. It was about 8 when we got the boats in. The "Naval Reserve" landed us at Callao.

We could not see land when we abandoned our ship. We altered the ship's course a point or two in towards the land before we saw the "Naval Reserve."

(*By Captain Harris.*) I think we had observed the smell of gas three or four days before we saw smoke.

(*By the Mayor.*) About four days after we saw the smoke we abandoned the ship. It was, I think, about eight days after we first smelt gas that we left her.

(*By Captain Harris.*) Our forecastle was close bulkheaded and the smoke came through the nicks. When under the line we felt no heat from the cargo. We went right round the Horn. The mate stopped at Callao; he had been ill a few days. During the voyage I am sure no water was thrown down into the hold.

(*By the Master of the Minnie Graham.*) You went off in the small boat to fetch the master of the "Naval Reserve," and the captain and carpenter of that vessel returned with you?—The captain of the "Naval Reserve" considered it unsafe to remain on board; he returned in our boat and sent his own life-boat to our assistance.

his
ROBERT × BALE.
mark.

EDWIN ELLIOT sworn, states :

I was cook and steward of the "Minnie Graham" on her last voyage. I joined her at Newport on the 16th, and she sailed on the 17th July last. I lived in the house on deck. I did not see the cargo shipped. On the voyage the fore and aft hatches were generally kept off in fine weather, that is, left off by day, we put them on at night; the four ventilators which were right aft and led on through the lazarette in the hold were metal pipes (I think lead), were kept open day and night in fine weather. In the month of October, four or five days before we left the ship, we smelt a strong smell of gas in the forecastle; the hatches had been off the day before; they were immediately taken off again; we then saw smoke, it came up in small curls at first; it gradually increased. The captain was called to see it; the men said they could not live in the forecastle; he went into the fore and after hold. I think the hatches were battened down after this till the Saturday before we left her. I suffered from the gas; I was ill from it; it laid me up. It came into the deck-house through the lazarette house just inside the door; I was bad all day, and could not observe what was going on. We caulked the lazarette-hatch down, and slept that night in the house as usual. We were rescued on Sunday. I was a little better that morning, but cannot say what happened. We saw the "Naval Reserve" just after dinner. The eboats were being got ready when she hove in sight with a view to abandoning the ship. We signalled her, and as soon as she got alongside our captain went on board in his jolly boat, and brought back the captain of the "Naval Reserve" and the carpenter; they examined our ship, took off the hatches, and smoke arose, a good deal, and gas. I saw Bale put several buckets of water down the hold. The captain of the "Naval Reserve" said it was not safe to remain on board; he was on board about a quarter of an hour before he said this. We were all called aft and asked what we thought we had better do. We said we had better leave her. He said it was not safe to remain on board as we did not know the moment she might blow up. The captain and carpenter returned to their ship and sent their life-boat to take us off. I saw the carpenter of the "Naval Reserve" go below into the lazarette with an augur in his hand, and I was told he bored a hole in her. One of the crew said so. The gas that made me ill appeared to smell like paraffin; it made me giddy and sick. I could not eat nor lift my head up. It made me rather short of breath and cough a good deal. I lost best part of my clothes. I was too ill to pick them up. We used an oil lamp in the deck-house.

EDWIN ELLIOTT.

GEORGE HARDY sworn, states:

I was an able seaman of the "Minnie Graham." I joined her the day before she sailed at Newport. I had been five years in a pilot boat, and this was my second foreign voyage. I lived in the forecastle. About three days before we left her (we left her on Sunday, the 26th of October), I noticed gas and smoke in the forecastle. It smelled like paraffin upset. It got worse and worse; it drove us on deck the night before we left her. There was no heat, but the forecastle got full of smoke. We could see it. It was reported to the captain, and he searched in the hold. He was driven back. Then we battened down the aft hatch, but the fore hatch was kept open, and the smoke escaped through it. The smoke got worse. We knew the ship was on fire; the stanchions were hot. So on Sunday we got the boats ready in the morning before the "Naval Reserve" hove in sight. We signalled to her, the ensign union down. She came to our assistance, and the captain and carpenter came on board, examined our ship, and we were called aft, and the captain of the "Naval Reserve" asked our opinion. We said we thought the ship was on fire. He said the same and we had best abandon her, as she might blow up or break out on us, and so we all left her. I saved most of my clothes; I went down into the forecastle for them. It was not quite so thick but what I could see my way to find them. We had thoughts of abandoning her before we saw the "Naval Reserve." We worked the pumps during the voyage. It took about five minutes to pump her out with one pump. The pumps were not choked. We were never more than 10 minutes at the pumps, and that was after a breeze.

GEORGE HARDY.

WILLIAM THOMPSON sworn, states:

I am an able seaman of the "Minnie Graham." I was the first to discover smoke on board. It was in the forecastle. When I got up in the morning I could hardly breathe. It was about eight bells. My head was like to split. I found gas and smoke in the forecastle. It smelt like paraffin. I reported this to the captain. I was at the wheel at the time. I went to the hold the second and third day after, and dug about two feet into the coals, and found plenty of gas and smoke to choke me. I came away, fearing I would be blown up altogether. We prepared to leave the vessel before we saw the "Naval Reserve." This was the third day after, (Sunday morning). That day was the first day the main hatch was taken off. The captain and carpenter of the "Naval Reserve" came on board, but I don't know what they did, as I was busy. The end of it all was we left her. We were called aft and our captain spoke to us. He asked what we thought of it. We said the ship was not in such a condition as we could remain on board of her. I was in the small boat which brought the captain and carpenter of the "Naval Reserve" to our ship, and remained in the boat. I have been 12 months at sea, foreign, having previously served five years' apprenticeship in a pilot boat.

By Captain Evans.

I made a mistake. Both captains were there when we were called aft.

WILLIAM THOMPSON.

WILLIAM COLLINS sworn, states:

I am a stevedore, and was in the hold helping to load the "Minnie Graham" with her cargo of coal. It was in the beginning of July last. I was with her the whole time she was loading. She had no stiffening on board; she did not want it. We put in small coal at first, slack; it was quite wet when we put in. It adhered to the trucks, it was so wet. We began with small wet coal. We put in perhaps about 40 or 50 tons of this, and then commenced with large coal. That was wet also. It was heavy rain the previous night, and the trucks were standing in it. I was paid for the cargo, 400 and some odd tons. She was full amidships. There was a good deal of room left fore and aft. We could have got 70 or 80 more tons in her. We were told not to let the coal go too far aft upon some wood, very inflammable. If you put a candle to it or against the side of the ship, it caught fire.

his
WILLIAM × COLLINS.
mark.

TOM JONES sworn, states:

I am traffic manager for Messrs. Powell. Coals from their two pits were put on board the "Minnie Graham." The cargo consisted of 60 tons 3 cwt. of Hope large coal, 20 tons 6 cwt. of Hope brush, 323 tons 1 cwt. of Tyrfilkin brush coal. No slack was mixed with the brush coal. The coal was fresh worked from the colliery when it was shipped. Some of the coal was in the waggons before being shipped 48 hours. That lot was 49 tons 9 cwt. The next lot was 91 tons 1 cwt. in the trucks, 30 hours; next lot 85 tons 8 cwt., in the trucks 24 hours; and 60 tons, in the trucks 24 hours; next lot 54 tons 11 cwt., in the trucks 54 hours; and next 59 tons 11 cwt., in the trucks 30 hours. When we commenced to load the vessel it was dry weather. Part of the cargo was out on Sunday and shipped Monday morning. The dates of the shipping were 11th, 12th, 14th, and 15th of July. The piece of coal produced I believe is Hope coal.

TOM JONES.

Adjourned till to-morrow morning, at 9 o'clock.

JOHN COOK sworn:

I am a shipbuilder. I have built many ships. With regard to ventilation, I believe there should be trunks laid fore and aft and ventilators up to the deck, trunks like a shoot. I produce a sketch I have made. (*The Court examined the sketch, and witness pointed out how the trunks should be placed.*)

JOHN COOKE,
Shipbuilder.

The Captain WILLIAM EVANS here put in his written statement.

ALFRED EDWARD HAYNES sworn, states:

I am a master mariner. I have commanded ships engaged in the coal trade. I have shipped coal at Swansea three times. I have had ships on fire from spontaneous combustion, one of the ships, the "Golondrina," took fire about 500 miles on the other side of Cape Horn. Her cargo was 630 tons of coal; it was mixed coal shipped dry; it was dry weather when shipped. I tried to extinguish the fire by boring a hole down below in the runnels and letting in water. I let in six feet. I then pumped her out after plugging the hole. I then put her on the other tack and let the same quantity of water into her and pumped her out again, opened all the hatches and found no fire only steam. At 4 o'clock next morning I saw fire coming out of her side in the upper works. We then prepared to leave her, and had to leave her. We had ventilators on board fore and aft on each side of the kelson, also in the bilges, and two up and down to the main hatch, two to the fore hatch, and one to the after hatch.

The other two ships were about the same tonnage. The "Corridora" carried a similar cargo shipped in dry weather; she was ventilated in the same way, and after 60 days out from Swansea, Cape Horn distant about 60 miles E.N.E., I discovered smoke coming up through the ventilators. We opened all the hatches and dug down as far as we could and found the seat of fire; heat increased till we got down and we found a calcined mass of white cinder-like lime. Smoke came from the hatches before we opened them. We found this seat of the fire near the bottom of the cargo. In 14 or 15 days afterwards the same ship took fire again from the same cargo. My men were brought out of the forecastle on to the decks in a state of insensibility. I went forward with my chief officer and found fire in the cargo near the foremast. I saw it through the platform boards. We dug down the fore hatch and got to the fire; it was right at the bottom of the hold on the platform about four feet from the ship's bottom; the fire extended eight or nine feet forward. We found a large mass of red hot coke, applied water to it, and put it out from our fire engine. We had 17 hands, all told, on board. Since this, we have altered the mode of ventilation. We now have trunk boards placed right fore and aft on each side of the midships stanchion, right up from the kelson to the decks. We also take the platform boards and put them on the 'tween deck beams. This leaves a width of 4 inches of ventilation right through the centre of the ship making as it were four separate cargoes. We are particular in taking in the coal dry, we would not ship it wet.

A. E. HAYNES.

DAVID PRICE sworn, states:

I am a master mariner and shipowner. I have shipped and carried cargoes of coal a great many times, principally from Newport. I never shipped smelting coal for the west coast. Always carried steam coal.

D. PRICE.

The following is the evidence given by M. Vassard to which the Court referred:—

ADOLPH VASSARD sworn, states—

I am an analytical chemist, and have examined three specimens of coal carried by the "Minnie Graham," No. 1 from the Hope Colliery, No. 2 Tyr Filkin, No. 3 small coal and coal dust. No. 1 is very brittle, and it shows two veins of iron pyrites, each vein measuring about a quarter of an inch, that is, half an inch in 4 inches of coal. It contains by weight three per cent. of iron pyrites, equal to 1·60 of sulphur. It absorbs water easily, 2 per cent. in five minutes. There is no binding power between the coal and the pyrites, so that the water passes through like a sieve. It contains 40 per cent. of volatile matter (gas and sulphur). No. 2 sample. This coal (Tyr Filkin) is more sulphurous than No. 1, the pyrites completely permeate the entire mass, which is a mass of sulphur. This is more porous than the Hope Colliery coal; this absorbs 2·8 per cent. It contains 5·25 of pyrites, being equal to 2·80 of sulphur, volatile matter being 49 per cent., including sulphur. No. 3 sample, small coal and dust, contains 6 per cent. of pyrites, which gives 3·2 of sulphur per cent. It emits only 37 per cent. of volatile matter, including sulphur. It contains also a large quantity of aluminous shale amounting to 6½ per cent. Shale would absorb a large quantity of water easily, which makes the coal dust adhere like mortar. Besides that the presence of shale facilitates the accomposition of pyrites to a great extent, on account of its great absorbent power. I have already given my theory in the case of the "Herbert Graham," on a previous inquiry, and am still of the same opinion as to the means to be adopted by ships carrying cargoes of coal.

From the evidence I have heard yesterday, I am of opinion that, considering the nature of the cargo of the "Minnie Graham," and the wet state in which it was shipped, no system of ventilation would prevent the cargo taking fire, and I am surprised that she did not take fire before. If coal was shipped in casks tight the coal would not ignite.

I produce slips of a letter sent by me to the Mining Journal on the subject of coal cargoes, expressing my view on the subject pretty fully.

With a cargo like that of the "Minnie Graham," spontaneous combustion is a mere question of time. Ventilation of heaps of coal exposed to the atmosphere is very efficacious. Ventilation of coal on board ship would be useless for want of proper circulation of air.

Report of a court of inquiry, held at the Townhall, in the borough of Newport, Monmouthshire, by order of the Board of Trade, before Nelson Hewertson, Esquire, Mayor of Newport, and Thomas Beynon, Esquire, J.P., assisted by Captain Harris, and Fenton Wake, Esquire, into the circumstances attending the burning and subsequent abandonment of the barque "Minnie Graham," which occurred on the 26th day of October 1873, in the South Pacific Ocean.

The "Minnie Graham" was built at Cremyl, in the county of Cornwall, in the year 1868, and registered at Newport, Monmouthshire, in the same year, 273 tons. She was owned by Mr. Robert Graham and others, of this port, and on this present voyage commanded by Mr. William Evans, who holds a certificate of competency dated 1867. The "Minnie Graham" left Newport on July 17th, 1873, manned by a crew of 10 hands, all told, and laden with a cargo of 414 tons, consisting of three qualities of Newport coal, all shipped in a very wet condition. Early on the 22nd of October a strong smell of gas was perceived coming up in the forecastle and the cabin aft. The hatches were opened, and the following day smoke was seen issuing from the fore and after hatchways. The long boat was removed from over the main hatchways, and upon digging down the coal was found to be greatly heated, and the iron stanchions extremely hot. Finding nothing could be done to extinguish the fire, the hatches were put on, and preparations were made on the 26th to abandon the ship, being then 700 miles or thereabouts from the port of Valdivia. On the afternoon of that day a vessel, the "Naval Reserve," of Liverpool, hove in sight, the master and carpenter of which came on board, and after taking the hatches off and examining the cargo, advised the abandonment of the ship. Accordingly a hole was bored in the run, by the advice of the master of the "Naval Reserve," in consultation with the master of the "Minnie Graham," and his chief mate; and the whole crew, with provisions and part of their effects, were taken on board of the former ship, and all landed at Callao. The loss of the vessel by spontaneous combustion was very similar to that of her sister ship, the "Herbert Graham," the coals in both instances having been shipped in a very wet condition. It must, however, be observed that there was more slack, or small smelting coal, on board of the "Minnie Graham" than in the former vessel, which, according to the evidence of Mr. Vassard, the analytical chemist, was more liable to produce spontaneous combustion. The time in which this took place was very nearly the same in both vessels. An analysis of the three qualities of coal shipped on board of this vessel showed that they were all of a very inflammable nature, containing large amounts of iron pyrites, the details of which will be found in the evidence. The Court then addressed itself to the question of ventilation, but with no better result than in the case of the "Herbert Graham." Some evidence was given by the master of a vessel who had tried the mode of ventilating by air shafts, which had signally failed, and these, on subsequent voyages, were replaced by trunk boards placed on each side of the midship stanchions fore and aft in the hold, which seemed to be more effective. The separation of the cargo, as far as practicable, appears to be the most desirable mode of carrying a coal cargo liable to combustion, but even this cannot be relied on for long voyages unless the coals be shipped in a dry condition. With these remarks we beg to refer to the valuable evidence of Mr. Vassard, which, together with that of the former inquiry, appears to have exhausted the subject. Having regard to the position of the "Minnie Graham" in the South Pacific when the fire occurred, and the great distance from any port of refuge, the Court did not consider the abandonment of the ship premature, and returned Mr. Evans his certificate.

Given under our hands at the Town Hall in Newport, Monmouthshire, this 14th day of March 1874.

NELSON HEWERTSON,
THOMAS BEYNON,
Justices of the Peace.

We concur in this report.

HY. HARRIS,
FENTON WAKE,
Nautical Assessors.

CORRESPONDENCE, relating to SPONTANEOUS COMBUSTION, between the BOARD OF TRADE and the LOCAL MARINE BOARDS in the UNITED KINGDOM, arising out of the case of the "PERSIA."

The Board of Trade considered the subject referred to by the Court in their report of the loss of the "Persia" of so great importance, especially as it appeared therefrom that three vessels had been burnt in 1868, and their crews taken into Mauritius, that they forwarded an extract from the report to each of the Local Marine Boards in the United Kingdom and to Lloyd's, inclosed in a circular requesting their observations thereon. The following are copies of the circular and its inclosure:—

Board of Trade, Whitehall,
February 1869.

SIR,

I AM directed by the Board of Trade to transmit to you for consideration the accompanying extract from the report of the Mauritius Marine Board on the loss of the 'Persia,' relating to the frequent cases of fire on board coal-laden ships.

The Board of Trade agree with the Marine Board in thinking the question one demanding serious consideration and would be glad to be favoured with any observations on the subject.

I am, &c.
T. Gray.

The Secretary to the Local Marine Board.
At .

Extract from Report of Mauritius Marine Board.

"In reference to this loss the Board would remark, that in their opinion the burning of coal-laden vessels demands the serious investigation of scientific men. These fearful accidents are increasing in frequency, and spontaneous combustion is hardly a satisfactory conclusion to arrive at. Why is there spontaneous combustion? Why does one ship burn from that cause, and dozens of others laden from the same pit, at nearly the same time, arrive safely at their destination? Is ventilation of the coal advisable or dangerous? Ought hatches to be kept on or off? Could not inflammable gases be pumped out of a ship's hold? Is there not a method of creating gases in an inexpensive manner on board ship that would smother and extinguish any amount of fire in a vessel's hold? Such measures are spoken of commonly enough, but are apparently never carried into practice. Three large coal-laden vessels, the 'Pernix,' 'Volante,' and the 'Persia' have been burnt at sea, and their crews arrived in this colony during the last year. What destruction of property? What risk to life? What privation and suffering do these burnings entail? At this moment there is a valuable vessel in this port, coal laden which narrowly escaped the same fate as the 'Persia,' the coals having been smouldering many days before they could be extinguished."

To this circular the following replies were received by the Board of Trade from the Local Marine Boards:—

Mercantile Marine Office, 2, Dean Street, Cork,
Sir, March 12th, 1869.

At a meeting of the Local Marine Board held today, Philip Scott, Esq., in the chair, my Lords' letter, M. 1658 of the 5th inst., was read, when I was directed to say that this Board fully recognise the necessity of some precaution or step being taken to prevent spontaneous ignition or combustion in coal-carrying ships, and would suggest that the opinion of scientific chemists should be taken at coal-loading ports. Mr. Scott directs me to say that he had ships for some years in the trade, and the precautions he used were as follows:—

The ship was platformed on a level with the kelson, and a wooden ventilator, 3 feet square, was placed in the centre of each hatchway; the top of the ventilator, 6 feet above the deck, and the bottom resting on the kelson in connexion with the platform. In stowing the coal care was taken to place good square blocks of coal at each side of the ventilator to prevent injury in loading up. He never had accident.

I have, &c.
John H. Hall,
Secretary.

To the Assistant Secretary,
Marine Department, Board of Trade.

Local Marine Board, 5, East India Avenue,
Sir, London, E.C., March 18th, 1869.

I am directed to acknowledge the receipt of your letter of the 5th instant referring to the accompanying copy extract from the Report of the Mauritius Marine Board on the loss of the 'Persia,' relating to frequent cases of fire on board coal-laden ships.

I am to inform you that this Board have directed their attention to this most important question, and they are of opinion that the subject of spontaneous combustion in the coal of this kingdom when stowed in large quantities in ships and the consequent danger and destruction to life and property, should receive the most serious attention from the community at large, with the view of discovering, if possible, some simple and available preventive.

The Board are also of opinion that stowing coals in a ship's hold in a wet condition is the principal cause of spontaneous ignition. Coals are never transported either in barges or railway waggons under cover, so that whenever rain or snow is falling the coals absorb it all. In all, excepting the coal ports, coals are taken to ships in open barges which may have been exposed to two or three days' rain, they are frequently taken on board in rainy weather, and this, it is believed, causes them to become heated when stowed in large quantities, and in hot weather and under certain circumstances, ignition is the result.

This Board could instance cases where vessels ventilated in precisely the same manner, and when the coal has been shipped comparatively dry, have made their voyages successfully, while others which have taken in their coal during wet weather have had partial ignition.

The modes of preventing the shipment of wet coals are obvious; when in the coal ports and under the shoots it would be necessary to cease loading when rain or snow is falling, and when coals are taken alongside in barges, these barges should be furnished with tarpaulings, and coals when shipped for voyages which might extend to a month should be treated as dry cargo, those in charge of ships declining, of course, to load in wet weather.

The Board are also of opinion that the more ventilation resorted to the better; this should be done in the most simple and inexpensive manner, or it will be evaded as the freights for coals, notwithstanding the danger of ignition, are always low.

The Board in this communication will not attempt to suggest how such ventilation can be best managed as various modes may be adopted by different persons which might be equally efficacious.

The subject, however, is of such vital importance that the Board would suggest a prize being offered for the best paper on the most effectual and simple mode of preventing the ignition of coal on board ship.

I have, &c.
John Domett.

The Secretary, Marine Department,
Board of Trade.

Local Marine Board, Sailors' Home,
Sir, Liverpool, March 19th, 1869.

I am directed by the Local Marine Board of this port to acknowledge the receipt of your letter of the 5th instant, accompanied by an extract from the report of the Maritius Marine Board, and in reply to state that they can arrive at no other conclusion than that the destruction of ships referred to, was the result of spontaneous combustion of the coals.

Without entering into the investigation of the causes of spontaneous combustion, it is sufficient to know for all practical purposes, that all coals are more or less liable to spontaneous combustion; that the longer they remain undisturbed the greater is the danger, consequently vessels conveying coals to India, China, or other distant countries are more liable to be destroyed by the spontaneous combustion of their cargoes than those on shorter voyages; that some coals are more liable to this accident than others, especially those coated with iron-pyrites; some coals abound with this mineral, whilst others *from the same pit* are frequently *quite free from it*. This may in some cases account for coals in some ships undergoing spontaneous combustion, whilst 'dozens of others laden from the same pit at nearly 'the same time arrive safely at their destinations.'

A well-arranged system of ventilation will undoubtedly prevent the decomposition of coals that leads to spontaneous combustion; but ventilation, when applied after decomposition is carried to a certain extent, hastens the conflagration; thus, in the case of the 'Hesperus,' no indication of fire was observed until she had arrived at her destination in China, and her hatches had been opened for a few days.

Ventilation is, however, the best means of preventing the chemical action that leads to spontaneous combustion, but to be efficacious must be so conducted as not to expose the coals to moisture, since dampness is one of the conditions that leads to the spontaneous combustion of coals; for the same reason a cargo of coals should be always put on board as dry as is practicable, and every means adopted to protect them from moisture.

Dr. Inman, the brother of Mr. William Inman, of the Inman line of steam ships, has directed a considerable amount of attention to the subject of spontaneous combustion generally, and if consulted by the Board of Trade would probably afford valuable suggestions on this subject.

I am, &c.
John T. Towson,
Secretary.

The Assistant Secretary,
Marine Department,
Board of Trade.

In accordance with this recommendation from the Local Marine Board at Liverpool, the Board of Trade forwarded an extract from the Report of the Mauritius Marine Board on the case of the "Persia," to Dr. Inman, stating that they would gladly receive and consider any communication relative to the matter which he might think fit to favour them with.

The following reply was sent to the Board of Trade by Dr. Inman:—

12, Rodney Street, Liverpool,
Sir, March 25th, 1869.

In answer to your request for information respecting spontaneous combustion, let me, in the first place, express my gratification that the subject has been taken up by the Board of Trade. My investigations into it, some years ago, taught me that it was a fertile source of fire on shipboard, and in warehouses, yet that great ignorance prevailed respecting this form of catching fire amongst those whose business was to store various goods on land or water.

As it is necessary to touch lightly upon the whole question ere I answer specifically respecting the spontaneous heating of certain coals, allow me to state that there are many things which ignite without the intervention of extraneous fire. Amongst these the most prominent are freshly-burned charcoal in powder or in bulk, lamp-black, cotton-flax, or other fibrous materials saturated more or less with vegetable oils; the worst oils being such 'drying' oils as linseed, which are rendered much more liable to ignite spontaneously when they have been boiled. These fluids when in bulk have no such propensity, for an extensive surface exposed to the air is necessary for the chemical change to take place that produced the heat. Practically, all materials that are said to 'dry' by exposure are liable to heat, the dryness referred to being due to the absorption of oxygen from the air, and not to the evaporation of a volatile fluid. From the cause thus indicated engineers cotton waste, used for cleaning oily hands or oily machinery, recently made oil cloth or tarpaulins, bales of fibrous materials upon which oil has accidentally dropped, or in which it naturally exists, are very prone to ignite spontaneously. In Liverpool a large fire was attributed to the ignition of a heap of matting and other material permeated by castor oil.

Certain vegetable products, amongst which grass and hay stand foremost, are liable to self-combustion; and it is doubtful whether certain cotton is not somewhat dangerous from the same cause.

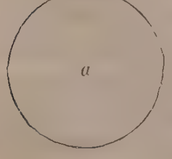
When spontaneous combustion arises it is brought about by chemical changes and the absorption of air.

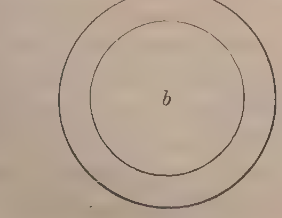
As an illustration of the former, I may mention that very pure iron and lead, in a state of impalpable powder, will become incandescent in a few seconds after being exposed to the air. Potassium sodium will do the like. In these cases oxygen has been absorbed, and a new substance formed. Amongst the substances liable to heat spontaneously by chemical agency is sulphur. This phenomenon is seen on a large scale in volcanic districts, wherein vast tracts are heated to whiteness by combination of sulphur with other elements. It is important to notice that coals frequently contain a large portion of this material, generally in the form of "pyrites." The ignition of haystacks is also due to a chemical change in the juices of the grass.

As an example of ignition by rapid absorption of air, I may state that barrels of freshly-burned charcoal finely powdered have been found red hot at a foot from the surface.

I must next call attention to a very important fact which, though it seems to be a truism, has not yet been duly appreciated, viz., "the hotter a thing is the sooner it ignites, and the faster it burns." As an apt illustration, take a bottle of rum from a cold cellar, and plunge a candle or other light into it, you will find that the spirit will not ignite, and will extinguish the flame. Allow that same bottle to remain in a temperature of 80 degrees, and the spirit will then ignite on the approach of a lighted candle. Woodwork, persistently in contact with steam pipes, will ultimately ignite spontaneously; and hot or warm painters' oils and cotton wool together will begin to ignite almost instantaneously, although some minutes elapse ere the heat rises to redness. To this subject we must allude again when we speak of the ignition of coals.

There are many materials which ignite spontaneously under certain circumstances which do not necessarily under all, and although it seems paradoxical the very same agent which prevents combustion in one may encourage it in another case. That which promotes ignition is access of air, but if the dangerous body be small in bulk, this access of air will carry away the heat produced as fast as it is formed. A certain bulk in the mass liable to be heated is necessary for complete ignition. I may express what I mean by two diagrams, *a* and *b*, both representing spheres of newly-burned charcoal, both equally absorb air and become heated, but the smaller sphere radiates away or otherwise loses its heat from the surface as fast as it is formed, but when the sphere is large the heat generated in the interior does not readily pass away, and it continues increasing, providing there is access of air, until a red heat is produced.





But if, knowing this, we should endeavour to cool the heated mass, or increase the current of air around it, with the same view we shall do no good, such a wind would operate as a blast upon a fire. If, however, the mass is cold to start with and of small bulk, good ventilation will prevent ignition. But in this case there is much danger, for a cask may be perfectly cold outside and incandescent in the middle, and in such a case ventilation would promote fire.

The fact that combustion may be proceeding in the centre of a mass whilst the outside is cold is readily recognised by the farmer who has to probe his hay-stack with a long iron rod before he can tell the extent of its heating, or if it is hot at all.

In one of my experiments I had a thermometer in the centre of a piece of cotton wool, on which I had sprinkled some painters' oil, yet these spots were so hot as to burn my finger, whilst the thermometer was unchanged. In a short time (half an hour) thereafter, half the mass was of a dull red heat, and on my simply touching it, the whole burst into a blaze. Whilst it was smouldering I could have saved half my cotton; after the flame arose this would have been impossible.

I must now call attention to the bearing of the law, "the hotter a thing is, the faster it burns;" thus, spontaneous combustion is a comparatively slow process; and requires a certain amount of bulk for its production; the heat in the mass steadily increases from without, inward ignition taking place at a distance from the surface; when, therefore, the inside is red hot, the outside is simply warm, but the whole mass heated by the chemical action becomes rapidly hotter as soon as it comes into contact with fire. Hence almost all fires arising spontaneously spread with amazing rapidity, for they take their origin from fuel peculiarly prone to ignite. Even the cook knows that hot wood will kindle the fire sooner and burn faster than cold wood, however dry.

When we consider that many of our ships travel for weeks together in a tropical climate, that their cargoes are kept perhaps at a temperature of 90° or more, the great importance of this law is at once recognised. All ships in hot climates are far more liable to ignition, and spontaneous combustion is more to be feared in them than in those trading in temperate zones. The more prolonged the heat the greater the danger.

Spontaneous combustion may be prevented or suspended by surrounding the material with any gas which does not support combustion, *e.g.*, nitrogen and carbonic acid. The first is innocuous to human life, the second is a deadly poison; a similar result may be obtained by preventing the access of air, as by surrounding the doubtful substances by tin or iron.

Having thus called attention to spontaneous combustion in general, I will address myself to the subject of coal. This material may be divided into two classes, the first of which is called anthracite, and appears to have undergone a sort of distillation by heat underground, and to be free from certain gases and sulphur; the second, or ordinary coal, contains a large quantity of gas in its interstices, and a notable amount of sulphur in the form of pyrites; the gas from it continues to escape from the time it leaves the mine until the whole is dissipated, hence old coals do not blaze, and coal in store always loses weight without there being peculation. In warm weather and when coal from fiery pits has been placed on board ship the gas extricated from the coal (carburetted hydrogen) mingles with the atmospheric air in the hold, and makes an explosive mixture that is liable to be fired by a sailor lighting his pipe, or by the galley fire. This danger continues for some time after the vessel has sailed, but may be obviated by careful ventilation.

The sulphur in the coals it is, however, which renders them most liable to spontaneous combustion, but there is some doubt as to the precise way in which it operates. In the absence of accurate chemical information the following broad facts may be stated:

1. A heap of slack in the centre of a coal yard will ignite spontaneously and in the central part first. This may be due to the same cause which operates in igniting freshly-burnt charcoal or lamp black, or it may be due to some chemical change with the sulphur. By some it is attributed to the decomposition of the pyrites by the influence of water or rain, or in the atmosphere. But none of these explanations can be regarded as otherwise than provisional.

2. A heap of coals stacked up, under cover, against a warm wall, whose temperature does not exceed 100°, will ignite spontaneously, combustion beginning in contact with the wall.
3. A heap of coals in a steamer's bunker, and in contact with the steam pipes or the warm iron-work around the furnaces and engine will ignite spontaneously, the change occurring first in contact with the heated surfaces. Sulphur being liable to ignition at a low heat, it is probable that this substance has a great deal to do with the combustion. It is, I believe, certain that the ignition does not occur in non-sulphurous coals.
4. In every mine there are, I believe, varieties in the relative amount of sulphur present in the seams and the various workings, and hence I conclude that in vessels laden with coals from the same pit, there may be considerable variety in the quality of the material as regards sulphur.
5. I think that I may safely say a large block of coal has never been known to ignite spontaneously; even when burned on a fire it consumes itself slowly.

We are now in a position to draw the deductions:
1. That slack is more liable to ignite than lumps of coal.
2. That heat increases the propensity to spontaneous combustion.
3. That sulphurous coal is dangerous according to the amount of pyrites that it contains.

Hence follow the conclusions:
1. That coal ought not to be shipped in bulk when a large amount of slack must necessarily exist.
2. That shippers or merchants should be recommended to eschew sulphurous coal, which are readily recognised by their containing much shining whitish or yellowish material that almost looks like metal.

As the existence of heat as a source of danger, is constant in tropical regions, and as some coal-laden vessels, even under such circumstances, escape combustion, it is necessary to investigate the probable causes of exemption. These may be stated to be,—

1. The quality of the coal on board.
2. The method of packing.
3. The actual temperature met with during the voyage.

Of the first I need say no more.

Of the second I would tell an anecdote. Shortly after reading an essay upon the subject in hand, a gentleman, to me unknown, communicated to me a patent that he had taken out for ventilating a coal ship's hold, so as to prevent the accumulation of heat or dangerous gases. The plan was simple, and I sought for evidence of its utility. Within a twelvemonth, however, I read a description of the loss by fire of three coal-laden ships, all furnished with this man's patent. Consequently I could not regard ventilation of the coal, however efficient, as a preventive against spontaneous ignition.

In trying to pick up what information I could, along our quays, I found the opinion generally entertained, that it was safest to send coal to tropical countries, wherever the material was not anthracite, in barrels, large pieces without slack being selected. In any published or private reports that have come to my knowledge no mention has ever been made of coal thus packed igniting spontaneously.

It will be understood that the coal ignites not from the presence of inflammable gases, but from the chemical change taking place between the sulphur and carbon in the material itself, favoured by warmth, or by the absorption of air or both combined. But as to the exact nature of the chemical action there is doubt, and I am not now in a position to clear up the subject, not being a professional chemist.

I am now able to answer categorically the questions and remarks in the abstract referred to me.

1. 'Spontaneous combustion" is a very adequate cause for explaining the destruction by fire of coal-laden ships, indeed, without the existence of heated coals, it would take a long time to consume a cargo of coals in a vessel's hold.
2. There is spontaneous combustion, because of the presence, in bulk, of sulphur, carbon, or slack, with a tropical temperature.
3. The ships ignited by such a cargo may have taken in their coals wet, moisture in slack promoting its heating, or their coals may have been very dusty, close packed, and generally small; or they may have been unusually sulphurous, or the weather may have been unusually hot. I once read of five ships from one port, carrying coals from one pit, sailing to the same destination at the same time, all igniting.
4. Ventilation of the coal is not desirable, except to get rid of the danger of explosion. It increases the danger of spontaneous combustion.
5. The hatches ought to be opened from time to time to explore the coals, &c.
6. Inflammable gases can be pumped out of a ship's hold; but these do not influence the combustion of the mineral.
7. Inexpensive gases, which will not support combustion, could readily be made to deluge the hold. One form is that of Philips' fire annihilator, which consisted of nitrogen and steam, in which men could work for a short time. Another is carbonic acid, that may be generated in large quantities from common chalk, limestone chippings, with diluted acid of some kind. This gas would prevent seamen going down the hold to inspect the seat of fire.

Yet there is reason to doubt whether either of these would do good. Without absolute knowledge, I suspect that the fire always originates close to the vessel's side, which is heated by the sun. Every timber contains a large amount of air in the cells of the wood; the fire would be fed thereby, even if the hold was deluged by the irrespirable gas.

It must be noticed, too, that if the gas did put out the fire, unless the coal were cooled, the mass would soon ignite again. Even when a coal-pit on fire has been 'put out,' air is not permitted to enter until the ashes are cold. This cooling is effected by steam or water finely divided, as by syringes.

After giving the subject of the transport of coals to India, China, or generally hot countries, much consideration, the conclusions that I have come to are the following:—

1. Iron ships are superior to wood, for wood supplies air, and may ignite.
2. That each ship should have iron partitions, iron decks, and light iron covers to fit over the coals, so as to make, as cheaply as possible, so many iron chests, which would be available for any cargo, and would permit but little air to enter.
3. Each receptacle for coal should be probed every day with an iron rod in many places, so as to ascertain the existence of heating, and iron tubes should be at hand to pour water on the required spot.
4. In wooden ships coal ought to barrelled, having been previously "screened," or if coal is carried in bulk, there should be some empty space left, or other contrivance by which the mineral could be turned over, as is malt in a mill, or wheat in a warehouse.
5. In vessels not specially adapted for the trade, when the coals have ignited, air must of course be excluded; and carbonic acid or other gas forced into the hold, half a ton of limestone chippings, and a carboy of spirit of salt; (muriatic acid, which is, I think, cheaper, and certainly better than oil of vitriol or other acid,) that might be diluted with sea-water, would be ample supply for a voyage. To complete the apparatus, there should be a stoneware retort, or large kettle, into which the lime and acid might be placed, and a hose passing from the spout into any appropriate hole cut or left for the purpose.

I trust that I have explained sufficiently the subject of spontaneous combustion in coals. To illustrate my views still farther, I am taking the liberty of forwarding a copy of my essay that was written in 1855. To me the matter has long been one of philosophical interest, and I have regretted that it is so little known. Of the pamphlet, only about half a dozen copies remain, but if the Board of Trade consider the matter of sufficient importance to be more generally known, and should desire my services as editor of a new edition, I shall be glad to give my assistance.

I am, &c.
THOMAS INMAN, M.D.

To the Assistant Secretary,
Marine Department,
Board of Trade, Whitehall.

"Local Marine Board, Sunderland,
SIR, 31st March, 1869.

REFERRING to your letter of the 5th of March instant, M. 1658, forwarding copy extract from the Report of the Mauritius Marine Board on the loss of the 'Persia' relating to the frequent cases of fire on board coal-laden ships, I am directed to inform you that at the meeting of the Local Board held on the 17th instant, the communications were handed to a sub-committee to go into and report; and at a meeting of the Board held to-day, the sub-committee brought up a Report which was confirmed by this Board, who resolved that the same with the papers annexed be forwarded to the Board of Trade.

I now therefore enclose the Report and papers herewith, setting out the views of this Board, and, I may add, that they consider the matter a very important one, and they have made a very full report on the subject.

I am, &c.
Robert Brown,
pro Secretary.

The Secretary, Marine
Department, Board of Trade.

Your sub-committee, having considered the questions submitted to this Board by the letter of the Board of Trade, dated March 5th, 1869, respecting the frequent cases of "fire on board coal-laden ships," have to report that they have not known any cases of spontaneous combustion on board ships load with north country steam coals. The cases which have come to their knowledge are mainly of ships laden with Welsh coals.

The cause of spontaneous combustion is in our opinion from the coals getting wet either before shipment or during the course of the voyage. We know that coals are frequently put on board in a wet state, as they are entirely exposed to the weather when they are conveyed from the pit to the ship. Cargoes shipped in this condition are very liable to spontaneous combustion.

The overloading of ships is a fruitful source of this evil, as it causes them to take much water on board at sea, a portion of which in all such cases makes its way among the coals, and, in many instances such overladen ships strain and leak, which increases the danger.

We consider that care should be taken that the water is not permitted to accumulate in the pump-well, so as to wet the coals in the bottom of the ships, particularly at the commencement of the voyage. Weight or pressure being one of the forces promotive of combustion the larger the ship, and the deeper the hold the greater will be the danger. But we think if coals are shipped dry and kept in that state with sufficient surface ventilation, fore and aft, at all times, it would effectuately prevent spontaneous combustion.

The reason why coals shipped from the same pit at nearly the same time, are conveyed safely to their destination by several ships, while one ship is burnt, is in our opinion to be accounted for by the cargo in the ship destroyed having become wet.

Respecting ventilation, we are satisfied that surface ventilation is right and good, and cannot be injurious unless combustion has taken place, but we think that shaft or funnel ventilation may be dangerous where the cargo has become wet.

We consider that hatchways should be kept uncovered in fine and dry weather, care being taken to prevent water going down upon the cargo.

Respecting the question of extinguishing and smothering fire in a vessel's hold by the application of gases, we are not prepared to offer any opinion on this scientific problem, our attention being particularly directed to the prevention of spontaneous combustion.

Thomas Anderson,
Chairman, Sub-Committee.

The following paper was also inclosed in the letter from the Local Marine Board at Sunderland to the Board of Trade:—

The Board of Trade send a Report of the Mauritius Marine Board relative to the loss of the "Persia," and other two ships, yet they don't mention the description of coal, if North Country or Welsh.

The writer having been loser by two ships taking fire, has caused inquiries to be made as to the loss of property. The two ships will be described as No. 1 and 2.

No. 1 had a cargo of Welsh coals, 700 tons, on board, and was ventilated by three wood ventilators going down each hatch, yet after completing nearly half her voyage out, she took fire and was totally lost; crew saved.

No. 2 ship also took fire; and the captain ordered a hole to be bored in the bow to let five to six feet in the hold, and by perseverance the ship arrived at her port, the quality of the coals destroyed, in fact, a portion of them were cinders. Each of these ships had wood ventilators and from a report from this ship by the mate, he states the after ventilation was stopped up with coals, and yet most remarkable, the cargo in this part was quite cool.

It is remarkable that, few (if any) of North Country coals ignite, and yet one colliery near Sunderland, shipping about 2,000 tons daily, seldom have a case of firing. This is remarkable, for the coals are sent immediately to the ships, but every precaution is taken in keeping the hatches off whilst in harbour.

The cause of spontaneous combustion is difficult to discover, yet from experience it is found that large coals are not so liable, and several of the cargoes that have lately fired, had a large proportion of dead small in. This by lying so close, like the heaps at the pit mouth, is very liable to take fire.

It is evident there is something in Welsh coals which is not in North Country coal, and yet it cannot be gas, for explosions at sea are never heard of.

As to ventilating, it is the general practice in Wales to put wood square box ventilators in each hatchway with holes in the side; this is objectionable, and if the cargoes have to be ventilated, a division fore and aft the ship is preferable; the hatches kept off whenever the temperature is not too high.

There can be no doubt that salt water with some coals will cause fire, see extract from Captain Edwardes' letter herewith.

And a tin manufacturer states they have their charcoal heaps take fire, and they dare not put water on. It only helps to spread it. They carefully avoid water and simply rake it out.

The subject of spontaneous combustion is a very important one to coal owners, shipowners, underwriters, and the lives of the crew. If a scientific inquiry was made we have no doubt a saving of life and property would follow.

Extract from Letter from Capt. W. Edwards, of Barque "Mangosteen," dated December 18, 1868, Coquimbo, to Messrs. W. Nicholson & Sons.

"I write to inform you of my safe arrival, after a long passage of 93 days, all well. The "Patagonia" and us, we arrived both together last Saturday evening and moored on Sunday morning. The "Patagonia" has discharged 60 tons of coal overboard. He told me they were on fire, but there is no appearance of fire now. I always think it is the salt water getting in the coals that makes them take fire, which on my arrival, hearing of so many ships taking fire, I tried the experiment and wet the coals in the main hatch on Sunday evening, and commenced discharging on Wednesday morning; the coals were that hot where they were wet that it was almost impossible to stand in them to fill them. I am certain they would have taken fire in three or four days, but as soon as the wet coals were discharged the others were as cool as possible. I think if the hatches are taken off every opportunity, if only for an hour, and the salt water kept from them, I don't think there is any fear of them taking fire.

Local Marine Board, Leith,
3rd April 1869.

Sir,

I am directed by the Leith Local Marine Board to acknowledge the receipt of your letter, M. 1658, of the 5th March 1869, transmitting for consideration copy extract from the Report of the Mauritius Board on the loss of the "Persia," relating to the frequent cases of fire on board coal-laden ships.

I am directed by the Board to report that they have been informed by Captain Thomas Lindsay, a member of the Local Marine Board, and also by several other captains of merchant ships who have had great experience in the command of coal-laden ships on long voyages. All these gentlemen give it as their opinion that *in all coal-laden vessels ventilators should be placed throughout the whole of the cargo up to the hatches, and that the hatches ought to be kept off as long as possible, when the state of the weather will admit of this being done*, a practice they state they have adopted for many years in carrying coals from various pits in the United Kingdom; by taking such precaution, they consider there is no danger of fire from spontaneous combustion on board coal-laden ships.

The Leith Local Marine Board, taking into consideration the opinion given by these very experienced ship-masters while in command of coal-laden vessels, beg to submit the same as worthy of the attention of the Board of Trade.

I am, &c.
Thomas Thompson,
Secretary.

The Assistant Secretary, Marine Department,
Board of Trade, London.

Local Marine Board, Dundee,
6th April 1869.

Sir,

I am directed by this Local Marine Board to acknowledge the receipt of your letter of the 5th ultimo, transmitting an abstract from a report by the Mauritius Marine Board, relating to the frequent cases of fire on board coal-laden ships.

The Local Board having had this subject under consideration, and being convinced of its very great importance, desire me to state in reply, that the branch of the subject relating to means that might be employed for extinguishing fires in such cases is so much a question of science that they decline to offer any opinion on it.

At the same time the Local Board is convinced that much might be done in the way of prevention by proper ventilation, and the Local Board would feel obliged by being furnished with the reports (for perusal) the Board of Trade has received following investigations in cases of the kind referred to, if any such investigations have been made.

I have, &c.
THE SECRETARY.

The Assistant Secretary,
Marine Department, &c.

Local Marine Board, Newcastle,
14th April 1869.

SIR,

I AM directed by the Local Marine Board to acknowledge the receipt of your letter of the 5th ultimo, together with a copy extract from the Report of the Mauritius Marine Board on the loss of the "Persia," relating to the frequent cases of fire on board coal-laden ships, and stating that the Board of Trade would be glad to be favoured with any observations on the subject.

In reply, I am to state that the Local Marine Board are of opinion that the subject in question is one that demands the serious attention of merchants, shipowners, underwriters, and all parties interested in the commerce of the country.

The Local Marine Board have felt it to be their duty to obtain the opinion of some of the most eminent colliery engineers in this neighbourhood, acquainted with the nature of the substance of coal, on the important subject in question. Gentlemen believed to be the best able to form a correct judgment on the points raised in the correspondence referred to, and in whose opinion the Local Marine Board have great confidence.

The following is the opinion of each of the gentlemen referred on each of the questions raised:—

1st Question.—*Why is there spontaneous combustion on board ship?*

Answers.

(*a.*) From the heat produced by the decomposition of the pyrites existing in the coal.

THOS. E. FORSTER.

(*b.*) Coal is a substance composed of many ingredients, all of which are, under certain circumstances, liable to the action called fermentation; but the most active agent is the presence of moisture in contact with iron pyrites, commonly called coal brass. It has been found in colliery practice that large heaps of coal placed on the ground in the unscreened condition are much more liable to take fire from this cause than similar heaps of the same coal put down in the screened condition. This difference is obviously due to the smaller amount of moisture held by the coal in the latter. There is no reason to suppose that this cause will be in any degree less active in ships laden with coal than in heaps of that mineral placed upon the gronnd of the same cubical measure.

JAMES EASTON.

(*c.*) It is caused by the decomposition of iron pyrites which ought to be separated and taken out before the coals are shipped.

JOHN R. LIDDELL.

2nd Question.—*Why does one ship burn from that cause and dozens of others laden from the same pit at nearly the same time arrive safely at their destination?*

Answers.

(*a.*) Some cargoes may contain more sulphur than others and salt water may get amongst the coals during the voyage.

THOS. E. FORSTER.

(*b.*) So far as the coal itself is concerned, there cannot be any great difference in the quality of that raised from any one pit or coal seam from day to day, except in the care taken to pick out all the pyrites, or other foreign matter, which also has a tendency to produce spontaneous combustion. The greatest difference will be found in the relative condition of the ships themselves, in regard to their water-tight conditions, especially in their decks and topsides, which in heavy weather may admit more or less water upon the surface of the cargo, as well as the care with which the bilge water is pumped out.

JAMES EASTON.

(*c.*) One cargo may contain the pyrites and others not, all depends on the cleaning of the coals.

JOHN R. LIDDELL.

3rd Question.—*Is ventilation of the coal advisable or dangerous?*

Answers.

(*a.*) I consider that ventilation is of little consequence.

THOS. E. FORSTER.

(*b.*) Ventilation of the cargo of coal can only be dangerous when the process of fermentation has passed through the incipient into that of active combustion, the former known by the smell of carbolic acid which accompanies it, the latter by an evolution of visible vapour, which is often inflammable. It is advisable in all cases to ventilate the coal placed on board a ship bound to a distant port, and more especially so when that coal is shipped in the unscreened condition, as it usually is when exported for gas making, or manufacturing purposes. The mode of ventilating a cargo of coal of the kind above alluded to in the most efficient and least expensive manner, is to use a considerable extent of wooden trunks or boxes of variable area to suit the size of the ship, say from 8 to 12 inches square inside. These should be placed horizontally, fore and aft of the ship, in one or more lines, and a few feet above the ceiling of the ship's hold, each line connected with the different hatchways of the ship by vertical trunks or boxes of the same dimensions, and reaching up to the under side of the hatches themselves. These air trunks, both horizontal and vertical, should be perforated with small holes wherever they are placed below the surface of the coal. These air trunks must of course be put into their places while the ship is being loaded, and should in no case be allowed to become filled with coal. It is also of very great importance that in all cases of wind and weather permitting the commanders of ships and their officers when carrying coal should be required to remove one or more hatches from every hatchway each day during daylight.

JAMES EASTON.

(*c.*) Desirable to be done with gas coals, not necessary with others.

JOHN R. LIDDELL.

4th Question.—*Ought hatches to be kept on or off?*

Answers.

(*a.*) Not of much consequence.

THOMAS E. FORSTER.

(*b.*) Answered in No. 3.

JAMES EASTON.

(*c.*) Hatches to be kept on.

JOHN R. LIDDELL.

5th Question.—*Could not inflammable gases be pumped out of a ship's hold?*

Answers.

(*a.*) Spontaneous combustion does not arise from the gases.

THOMAS E. FORSTER.

(*b.*) Inflammable gas can only arise in a ship's hold from two causes; the first is from the gas contained in the pores of the coal on its severance from the coal seam, and is not dissipated in the course of its transit and shipment, and many explosions have arisen from this cause by reason of the hatches having been placed on the hatchways immediately on the vessel having been loaded. The other cause is derived from the coal when the incipient combustion is about to burst into the active condition.

JAMES EASTON.

(*c.*) Don't think pumping practicable.

JOHN R. LIDDELL.

6th Question.—*Is there not a method of creating gases in an inexpensive manner on board ship that would smother and extinguish any amount of fire in a ship's hold?*

Answers.

(*a.*) I do not consider this practicable.

THOMAS E. FORSTER.

(*b.*) There is a method of making a gas that would be inexpensive on board ship or elsewhere, and if it could be applied direct to a fire would certainly assist very materially in extinguishing it. The difficulty of its application to a fire, and that attending the exclusion of atmospheric air at the same time, would render its effect extremely uncertain.

This gas produced by the application of *dilute* muriatic acid to dry chalk or marble, and called carbonic acid gas, would be readily made on board ship by the use of a few old tubs or casks, but considerable risk would attend going below for some time after its application.

James Easton.

(*c*.) I believe not.

John R. Liddell.

The Local Marine Board from their own experience can say that in all well-managed ships loading from this district for foreign ports and distant voyages, the practice observed is to give as full and as free ventilation as possible during the loading, and whilst in harbour prior to sailing; and when the weather permits at sea to open all hatches, using wind sails, &c., care being taken to keep the coal free from moisture.

I have, &c.
Wm. Storey Whitfield,
Secretary.

The Assistant Secretary,
Marine Department,
Board of Trade, London.

Local Marine Board,
Belfast, 14th April 1869.

Sir,

With reference to your circular of the 5th March last, M. 1658, I am directed to state that this Board considers that iron lower masts, perforated below and above, by acting as funnels to carry off inflammable gases, would greatly tend to the safety of coal-laden vessels on long voyages.

I have, &c.
A. Atkinson,
Secretary.

To the Assistant Secretary,
Marine Department,
Board of Trade.

Local Marine Board, South Shields,
16th April 1869.

Sir,

I am directed by the Local Marine Board to acknowledge the receipt of your letter of the 5th March last, accompanying copy extract from the report of the Mauritius Marine Board on the loss of the 'Persia,' relating to the frequent cases of fire on board coal-laden ships, and requesting to be favoured with any observations on the subject.

And I am to state that, in the opinion of this Board, danger of fire on board coal-laden ships appears to arise from two causes:—(1) from the coals being laden in a damp state, or from their becoming wet afterwards from the casualties of the voyage; and (2) from the cargo containing in some cases a considerable quantity of carburetted hydrogen gas.

When coals are to be shipped for a long voyage they should not be allowed to be taken in after any considerable exposure to wet; and whether for a short or long voyage, coals from workings known to contain explosive gas should not be shipped without having stood some days (protected from wet) to allow the escape of gas as much as possible.

From the experience of several members of the Local Marine Board, they are convinced that proper ventilation is advantageous, and ought in all cases to be provided for. This can be cheaply and efficiently done by wooden vertical ventilators properly perforated, their number and position being regulated by the size of the vessel. If they are connected by horizontal tubes the ventilation will be more perfect. They need not be brought above the hatches, which, moreover, should be opened from time to time, whenever the state of the weather will allow without exposing the cargo to wet.

The plan recommended in the Shipping Gazette (19th February 1869) appears likely to abate materially if not entirely to remove danger from fire, but the Local Marine Board are of opinion that the object can be obtained by less expensive means.

But by whatever means it is to be accomplished, the Local Marine Board would urge the absolute necessity of providing sufficient ventilation.

I am also directed to send for the consideration of the Board of Trade the annexed remarks on the subject by James Mather, Esq., a member of the Board, whose knowledge of the chemistry of gases, and whose experience in relation to pit accidents and explosions, render these remarks worthy of attention.

I am, &c.
Your obedient servant,
J. W. Lamb.

The Assistant Secretary,
Marine Department,
Board of Trade.

Mr. J. Mather's Paper.

Oxygen 1·000	Carburetted Hydrogen. 0·555	Nitrogen 0·9722
Life and Flame giving.	Explosive Gas. Mines.	Destructive gas.

To clear ships from the effects of cargoes of coals, the light carburetted hydrogen gas, the inflammable gas of mines, which becomes hot, and then bursts into flame by spontaneous combustion, and renders it dangerous for the ship to be exposed to it. This gas is about half the weight of common air, 0.555. It is found sleeping in the upper part of mines, or seeking to free itself from deposited or broken coal, or detaches itself from amongst water, and comes to the surface, and rises to the atmosphere where it is received.

Nitrogen is absorbable by about 100 volumes of water, and extinguishes flame. Its specific gravity is about 0·9722. The nitrogen forms about four fifths of the atmosphere, is unlike its oxygen, does not add light to combustibles, but on the contrary extinguishes it; the carburetted hydrogen dies in it. It being pumped through wooden or metal pumps perforated with holes from 1-inch or to 2-inch holes, the latter, if thought proper, to be covered with wire gauze or with perforated zinc, where it will be diffused when carried to the atmosphere, the breeze absorbing it; and thus will the threatened catastrophe of this great maritime calamity be mastered and dispersed.

James Mather,
Member of the Local Marine Board, South Shields.
April 14th, 1869.

The Gases produced in Coal Cargoes.

To clear ships from the dangerous concomitants of coal cargoes, it is simply necessary to pump out the light carburetted hydrogen from the hold, and thus free them from this gas, which becomes heated and spontaneously bursts into flame. This gas is about one half the weight of common air (0·555). It is always found floating about the upper part of mines, or seeking to creep away from deposited or broken coal, or detaches itself from amongst water and rises to the surface, thence passing away into the atmosphere.

Nitrogen also found amongst coal is absorbable by about 100 volumes of water. Its specific gravity is about 0·9722. It extinguishes the flame of the light carburetted hydrogen.

Wooden pumps perforated with holes, reaching to the decks from a platform laid upon the keelson, would certainly cause the carburetted hydrogen to find its way to the decks, whence it would be harmlessly diffused in the atmosphere.

The usual and safe way is to fill in the coals around the perforated tubes. These perforations should be one inch, or even two or three inches in diameter. In the latter case the holes might be covered with strong gauze or perforated zinc, whereby the inflammability of the carburetted hydrogen would be materially abated, if not entirely destroyed, whilst the pumping would discharge this gas freely upon deck, whence it would be swept away by the breeze.

By this simple process I think all danger of such fearful catastrophes as have occurred will be obviated.

James Mather,
Member of the Local Marine Board, South Shields.

Local Marine Board, Greenock,
7th May 1869.

Sir,

Referring to your letters of the 2nd and 5th March, I now enclose a report by a committee of this Board adopted at a meeting of the Board, held on the 27th ult., on the subject of spontaneous combustion in coal-laden vessels.

I am, &c.
Thomas King, Secretary.

The Assistant Secretary,
Marine Department, Board of Trade,
Whitehall, London.

The Committee of Marine Board on spontaneous combustion in coal-laden ships, after considering information obtained from various parties likely to be well informed on the subject, report as follows, but with reference solely to the Clyde district.

Conflicting opinions are entertained as to the cause of recent casualties to coal ships loaded in the Clyde, (vessels loaded there having for many years, till within about a year ago, enjoyed an immunity from such casualties,) but there seems to be a general agreement of opinion that spontaneous combustion at sea arises more frequently from loading what is locally named main seam coal, which contains much sulphurous matter, than from the other principal seams in this neighbourhood called ell and splint, also that mixed coal, viz., cargoes loaded from different pits, are from whatever cause more likely to ignite, than those loaded altogether from one pit, and that especial danger arises from coal being loaded in a wet state.

Suggestions in the way of remedy which the committee venture to make are,—

1st. That it is safest to ship only splint coal for long voyages.
2nd. That cargo should be as far as practicable loaded from one pit.
3rd. That the greatest care should be taken to secure the shipment of coal in as dry a state as possible.
4th. That ships' holds should be efficiently ventilated, and to aid ventilation that the hatches should be taken off at sea as frequently as possible.
5th. That some simple plan should be adopted for ascertaining and recording the temperature of the hold daily or oftener, so that the earliest possible notice may be given of danger.

The whole subject is surrounded with difficulties, and perhaps ought on account of the conflict of opinion to be reported on by eminent chemists. The Committee therefore hesitate to give any very decided opinions on the question.

JOHN H. CARMICHAEL, Convener.
Greenock, 23rd April 1869.

Local Marine Board, Glasgow,
2nd June 1869.

SIR,

AT a meeting of this Board on the 31st ultimo, I was directed to acknowledge receipt of your communication of 5th March last transmitting for the consideration of this Board a copy of an extract from the report of the Mauritius Marine Board on the loss of the 'Persia,' relating to the frequent cases of fire on board coal-laden ships, and requesting the observations of this Board on the subject, and I am to state that the experience of the members of this Board was against spontaneous combustion, that in their opinion ignition was usually caused, either by leakage, or by the coals having been shipped in a wet state, and that they would recommend that care should be taken that coals are shipped dry, kept so during the voyage, and thoroughly ventilated.

I am further to state that the members resolved, if possible, to obtain the opinion of practical men on the subject, and that any information so obtained will be duly reported to the Board of Trade.

I have, &c.
J. MUIRHEAD,
Secretary.

The Assistant Secretary,
Marine Department, Board of Trade,
Whitehall, London.

The following letters were also received at this time by the Board of Trade on the subject of spontaneous combustion in coal ships:—

1st. On 24th March 1869 Mr. Towson of Liverpool forwarded a copy of the printed slips issued since Dec. 1867 by the Liverpool Salvage Association, containing the following report on the system of ventilation in coal ships, with suggestions for its improvement:—

FIRES IN COAL SHIPS.

REPORT ON THE PRESENT SYSTEM OF VENTILATION, AND SUGGESTED IMPROVEMENTS.

Salvage Association: Underwriters' Rooms, Liverpool,
Monday, December 16, 1867.

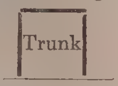
The mode of ventilation at present adopted here on board of vessels taking coal cargoes for long voyages is to place a vertical shaft down each hatchway, composed of two strong boards about 24 inches apart, connected by short pieces of wood, which overlap each other like a Venetian blind; these shafts rest on the keelson, and are usually connected together by horizontal trunks which run fore and aft on each side of the keelson, and are formed by boards which rest on the ceiling and lie obliquely against the keelson.

These shafts and trunk have hitherto been considered sufficient to allow the escape of any gas which may emanate from the coal, and to allow the circulation of sufficient air to carry away any heat which may be generated in the hold of the ship.

The burning of three or four coal-laden ships from this port, and the reports from other vessels which sailed hence and which have arrived at their destination with their cargoes in a very heated state, indicate that this method of ventilation is not sufficient, or that it is not adequate to the ventilation of large ships.

It has been supposed that in ships which are laden at the coal tips the great weight of the coal thrown in at once may break the trunk or shafts, and allow small coal to fill them in places, and that occasionally the coal may even be projected into the top of the shaft, and that thus the proper circulation of air through the shafts is prevented.

After duly considering the subject, and without denying that accidents to the shafts and trunk may sometimes occur while the vessel is loading, the surveyors of this Association have come to the conclusion that in large ships a much more extended system of ventilation should b adopted. *They attribute the heat to the spontaneous and slow combustion of the small and dust coal in the bilges, and think it can be traced to this small coal becoming wet during the voyage, or to its being shipped in a more or less damp state.* On the supposition that the fires reported are due to this cause, it seems not unlikely that a limited supply of air would tend rather to hasten than retard the combustion of the coal. With a view, therefore, to give such a quantity of air as will keep the cargo cool, they suggest that, in vessels of 900 or more tons, a trunk, similar in section to the annexed figure, and formed of stout planks, shall be carried fore and aft, about 3 feet above each bilge, and that these shall be connected by transverse trunks to the vertical shafts which lead up to the hatchways. These are in addition to the usual trunks alongside the keelson.



In ships of large burthen which have no 'tween decks laid, two additional trunkways should be placed fore and aft on the top of the 'tween deck beams, and these should also be connected by transverse trunks with the vertical air shafts.

There is another system of ventilation of coal cargoes which the surveyors to this Association consider may advantageously be adapted in those ships which are permanently fitted with the large flange ventilators which run down to the lower deck at their fore and after ends, as in the Australian or American packet-ships, viz., that of trunks running horizontally through the whole body of coals to the fore and after ends of the vessel beyond the cargo, and connected with the flange ventilators, by means of which currents of air could be made to pass through them from aft to forward, or forward to aft, according to the direction of the wind at the time.

Either of these plans, it is thought, would tend to reduce the risk of fire to which coal-laden vessels are now exposed.

It is also suggested that the temperature of the air in the shafts or trunkways should be taken every night and morning and recorded in the ship's log-book, as such observations would indicate the presence of heat in the hold long before it could reach any dangerous degree.

---

2. The following letter from Mr. George Fawcus, of North Shields.

North Shields,
April 27th, 1869.

DEAR SIR,

I BEG leave respectfully to submit for your consideration the following suggestions to prevent the so frequently recurring explosions on board of gas coal laden vessels.

Many plans have been tried to ventilate *the hold up to the deck,* by means of perforated boxes alongside of the keelsons, boarding alongside of the hold beam stanchions, or shafts up to the hatchways, &c.

A simple plan now seems wanted to allow the gas to escape *from underneath the deck without allowing water to fill the hold.*

There are two ways of doing this, either by ventilating tubes in the way of the masts amidships, or in the way of the rigging at the sides.

A metal tube closed up to the hold beams and perforated between the hold beams and the deck, and carried up, say, four feet above the deck, would serve as a ventilator to the hold, and also as a well for sounding the pump well without drawing the pump boxes. The end of this tube could be left open always, with safety, in a coal-laden vessel, and in vessels with damageable cargoes could be closed with a plug during bad weather.

A tube could be placed on the rails (protected by the rigging), communicating with ventilators or air ports in the between-deck ceiling, the covering boards, and a water-tight space between two stanchions under the rail.

I am, &c.
GEORGE FAWCUS.

The Assistant Secretary,
Marine Department,
Board of Trade,
Whitehall, S.W.

P.S.—Grain cargoes also require ventilating.

And 3rdly, two letters from Mr. W. C. Perry, of which the following are copies:

West Hartlepool,
20 Scarboro' Street,
May 25th, 1869.

SIR,

I BEG to acknowledge the receipt of your letter of the 19th instant, stating that the Board of Trade is prepared to receive any observations upon the causes of spontaneous combustion in coal-laden vessels.

The remarks I have to submit are few and simple, and apply only to vessels making sea voyages, and I will ask permission to repeat a former question, whether the risk of these disasters would not be greatly lessened if this kind of freight were confined to iron ships having nothing of wood below the upper deck.

1. An admitted cause of spontaneous combustion of coal is that of its being shipped wet, and when the form of the trucks used for conveying coals to ships is considered it will appear how it happens at times that it is shipped very wet.
2. The form of these trucks is that of an inverted cone, and in consequence there is a very large exposed surface, sufficient in a single day's rain to allow the whole mass to be penetrated with this wet.
3. From want of skill in working, or from the nature of the material, there is a large proportion of small coal shipped in these parts, and this greatly increases the danger in wet weather, and from some experiments I have made since the receipt of your letter it is apparent that small coal has a capacity for retaining moisture, beyond what is likely to be considered. In this particular, as well as in mineral difference, the Welsh steam coal appears better and safer for long transport.
4. The remedy suggested is that all sea-going ships be loaded from covered trucks (or "waggons"). A light inexpensive cover open at both ends and removable when not required could be fitted in a way not to interfere at all with loading and discharging.
5. Another known cause of spontaneous combustion is that of the gases in some kinds of coal. In a deep mine in the north I was led to notice the incessant sound of gas escaping from a "new working" and it is not easy to doubt that if coal in this state were at once to be shot down a ship's hold it would be unsafe. The remedy appears to be exposure to the action of the air for a sufficient time before being put on board.
6. Passing to the possible causes of spontaneous combustion, may there not be cases where the condition of the hold from a previous cargo has operated in this way? As an instance, may not coal after guano (especially in wooden vessels) be an originating or at least an accelerating cause of generating inflammable gases.
7. Whether in some instances of apparent spontaneous combustion in cotton and in wool-laden ships the cause may not be due to excessive friction of the cargo at certain points in the hold when the ship is labouring heavily in a high sea?
8. Concerning the question as to whether ventilation is advisable in coal-laden vessels, I would submit whether partial ventilation is not more calculated to aid combustion than to check it, and that unless ventilation can be carried out more effectually than by any means yet discovered, it would not be safer to keep the hold shut up, and in an emergency to resort to flooding rather than to any other means.

I am, &c.
W. C. PERRY.

Assistant Secretary,
Marine Department,
Board of Trade.

Cantreff House, Abergavenny,
July 8th, 1869.

SIR,

SUPPLEMENTARY to my letter of 25th May I beg to offer one or two other observations upon the subject of spontaneous combustion in coal-laden vessels.

Disregarding doubtful causes of these disasters, there are two held certain: first, moisture either at the time of loading or afterwards; second, the gas contained in the coal.

MOISTURE.

From experiments I made in the north, I found that the amount of moisture coal will retain varies not only with the size of it, as was to be expected, but with the quality; so that hardly any two samples from different mines in the same district appeared alike in this particular. The small stuff called 'duff' retained 6 per cent. of moisture, which in a cargo of 1,000 tons would give 60 tons of water, and although this is an exceptional case, it is to be noted that general moisture or dampness in a coal cargo is not at all required for combustion. In local and probably very limited centres of moisture may be found the germs of danger, and to a single waggon of wet coal at loading might be traced the destruction of a ship at sea.

Hence, as I before submitted, the importance of not allowing sea-going ships to be loaded from open waggons in all weathers.

GAS.

To illustrate the necessity of exposing some kinds of coa to the action of the atmosphere before loading, it is only necessary to mention that I have notes of nine cases of explosions which occurred shortly after the loading had been completed.

VENTILATION.

It does not seem as if the question of ventilation can be met by fixed rules, as on account of variety of circumstances cases require to be dealt with differently, and I would submit to your department as a subject for inquiry, the difference between the gas or gases native to the coal, and which occasioned the explosions alluded to above, and the gas or gases generated from wet coal.

The former requiring the contact of sparks or flames before explosion, the latter resulting in spontaneous combustion.

I am, &c.
W. C. PERRY.

Assistant Secretary,
Marine Department,
Board of Trade.

The following CASES of SPONTANEOUS COMBUSTION in COAL-LADEN SHIPS, which have occurred since the appointment of the Royal Commission for inquiring into the Cause of the Spontaneous Combustion of Coal in Ships, have been reported to the Royal Commission by the Board of Trade.

"AURELIE" barque of Quebec, 548 tons register, six years old, and classed L. 11 Veritas, for nine years.

REPORT of a NAVAL COURT held at HER BRITANNIC MAJESTY'S CONSULATE GENERAL, NEW YORK, on Friday the 3rd day of September 1875.

PRESENT:

E. M. ARCHIBALD, Esq., C.B., Her Britannic Majesty's Consul General, New York, President.

THEODORE COOK, master of the steamship "Russia," of Glasgow, O.N. 58312.

WILLIAM WALKER, master of the ship "Greenock," of Greenock, O.N. 66083.

The court was assembled for the purpose of inquiring into the circumstances connected with the loss of the barque "Aurelie," of Quebec, official number 59894, which vessel foundered and was lost at sea on the 7th August last.

The late master of the "Aurelie," Octave Côté, the chief mate, James Bailey, and the scond mate, Alphonse Côté, were in attendance, and, being respectively examined, stated as follows:—

OCTAVE CÔTÉ sworn:—I was master of the barque "Aurelie," of Quebec. I took command of her on the 17th of October 1873. I hold a certificate of competency as master of the "Dominion of Canada," No. 621.

The "Aurelie" was a wooden ship of 548 tons burthen, built at Quebec in 1869. She was coppered. We took in a cargo of coal at Liverpool in April last in the Bramley Moore dock. We were occupied two days in shipping it. It was English steam coal, brought from some place near Liverpool. I cannot say from what place it came. It was bituminous coal. I cannot say whether it was Welsh coal or not. We took in 701 tons. My opinion is that it was English, and not Welsh. As far as I can recollect, the weather was fine and dry. I know that the second day that the coals were shipped was a very fine day. I do not recollect that it rained on either of those days. The coals were apparently of good quality and good order. The vessel was not completely loaded; she could have carried 150 tons more. I have never carried a cargo of coals in this vessel before. She had a freeboard of fully six feet. She was in good order and well found in every way. She had just been newly coppered in April. Her class was L 11 Veritas. She had been classed for nine years, and there were three years then to run. Our crew and myself were 14, all told. We sailed from Liverpool on the 16th of April for Barbadoes and a market. We arrived at Barbadoes on the 31st of May without any occurrence worth mentioning.

We remained at anchor in Carlisle Bay for 20 days. There was no sale for the coal there, nor in the neighbouring islands to which I telegraphed; and having received orders from my owners to proceed to Montevideo, we sailed from Barbadoes for Montevideo on the 20th June. We had very fine weather during the time we lay at Barbadoes, not very hot. We had the fore hatch, or rather one half of it off, during the time we lay there, in order to ventilate the ship. There were two or three showers during the time, but when it rained the hatch was put on, and the cargo covered. We left Barbadoes with strong trade winds and ran to the eastward until we were in about 32° north latitude. After that we had light and variable winds, but beautiful weather, until the 1st of August, when we were in 16° 39 north latitude, and 30° 16′ west longitude. Between 6 and 8 o'clock on the evening of that day the second mate reported to me that there was fire in the hold. He said he judged so because there was unusual heat and gas. I went at once into the hold and digged down into the coals about a foot, near the quarter hatch; I put my hand on the coal where I had digged and found the coal so hot that I could not bear my hand on it for a minute. We were then on the port tack stretching to the southward. The crew wished me to turn back to Barbadoes. I said I would not, as Pernambuco was quite as near, and that when it would be daylight on the morrow we could see better what was best to be done. Next morning I took a jack stay, an iron rod about 15 feet long, which I shoved down through the coal at the quarter hatch to a depth of about 12 feet, This was at 5 a.m. on the 2nd of August, I left the rod in the coal for two hours, and then drew it up. The middle part of it was red hot, the bottom part cool, and the upper part so hot we could not handle it, but had to put straps round it. At 7 o'clock I decided to bear up for Barbadoes, in order, if possible, to save the ship. As soon as we drew up the rod the smoke followed and burst up. Some of the crew also digged down with shovels some 3 feet, and about 5 or 6 feet from the ship's side, and the smoke came up so strong that the crew could not stand it. I ordered them to fill up the hole again and come on deck, and then I had the hatches closed down tight, and we abstained from pumping, so that the water might rise in the ship, and if possible extinguish the fire. We made all the sail we could for Barbadoes. We perceived the smell of wood smoke, and knew that some of the beams must be burning. On the 3rd of August the fire increased, and the deck became hot. I left part of the forehatch open, to permit the smoke to escape, and also least the gas might blow up the ship. We got the longboat over the side and fitted her, in case we might have to leave the ship. On the 4th the heat and smoke still increased, and we got the chains on deck lest the heat should prevent us. On the 5th August smoke and heat still increased greatly. The pitch was boiling in the deck seams, and we could no longer live in the cabin on account of the dense smoke and gas. All the ropes and gear from below were got on deck.

On the morning of the 6th of August, it became evident that the ship must be abandoned, as she was then burning. We got out the second boat and provisioned it, taking as few clothes and effects and as much food as possible, as we we were then 1,500 miles from land. At noon on the following day, the 7th of August, we pumped the vessel dry. This was the first time we pumped her after the discovery of the fire. At 4 p.m., on sounding again, we found 3½ feet of water, showing that her side must have been burnt through. At 5 p.m. she had about 6 feet of water in her; at all events she was settling fast. We then all took to the boats and lay by the ship until 9 p.m., when she sunk. Besides our crew, there was my wife and an infant child of about two years. We steered for Barbadoes, the two boats keeping together from the 7th of August until the 10th of August, on which day, at about 7 a.m., we were picked up by the American ship "Moonlight" from Batavia bound to New York, and were brought in that ship to this port, and landed on the 31st ultimo. My wife was confined on board the "Moonlight," and gave birth to a male child on the 28th ultimo.

I suppose the cause of the fire was spontaneous combustion. The ship made regularly nearly one inch an hour of water on the voyage out to Barbadoes. After leaving Barbadoes she did not make more than three-quarters-of an-inch per hour. She was regularly pumped dry twice a day. I suppose that the damp or water rising up through the coal, in connexion with the sulphur in the coal, generated combustion. The coal was loaded on the skin of the ship, that is the usual mode. The bilge-water never could have risen to the skin, except when we left it after the discovery of the fire. I do not know whether the ship or cargo were insured.

H.B.M. Consul General,
President.

James Bailey, examined: I was chief officer of the late barque "Aurelie" of Quebec. I joined her at Liverpool on the 16th of April last. I hold a mate's certificate of servitude, No. 79,049. I superintended the loading of the ship at Liverpool. We were two days taking in the cargo of coals. They were common house coals. I do not know where they came from. The hold was dry when we took them in. The weather was dry while we loaded. No rain or wet got on them at that time. I remember the discovery of fire in the coals on the 1st of August. It was my watch on deck. The second mate first reported it. On the following morning we pierced the coals with an iron rod, and left it for two hours, and when it was drawn up the rod was red hot. The smoke and heat increased from day to day until the 7th of August, when we were compelled for the safety of our lives to leave the ship. There was nothing in our power which we could have done which would have saved the ship. The cause of the fire must have been damp among the coals, and they had been nearly four months in the ship. I have been two voyages to Bombay in ships with coals from England, we had no fire on either occasion.

The length of each voyage was about three-and-a-half months. We were perhaps about a month in passing through the tropics.

I think that being detained for a long continuous period in the tropics would increase the hazard of fire in a coal cargo. (The master's statement was here read to this witness.) The statement of the master is quite correct so far as I recollect. We had very moderate weather the whole voyage from Liverpool, and did not lose even a ratline.

(Signed) James Bailey.

(Signed) E. M. Archibald,
H.B.M. Consul General,
President.

Alphonse Côté.—I was second mate of the late barque "Aurelie." I am brother of the master. I remember the occurrence of the fire on the 1st of August last. One of the sailors and cabin boy said to me they smelt fire below. I then went into the hold; this was about half-past 6 in the evening. I did not see anything, but I smelt the gas very strong. I then went and reported it to the master. He came immediately and went below, and made an examination, and we all smelt the smoke.

The same night I digged a hole about two feet and a half deep in the coal, and I could not bear my hand on the coals they were so hot. Next morning we pierced the coals with an iron rod, which when drawn up was red hot. The smoke and heat continued from day to day until they were at last unbearable, and we were obliged to leave the ship. The crew wanted to leave earlier lest the flames should burst out, but the captain stayed as long as it was possible. We made all the sail we could to return to Barbadoes; but we were very far from land. Nothing could have been done, in my judgment, to save the ship. She sunk in about five or six hours after we cast off from her. We saw her go down. We were nearly four days in the boats when we were picked up and brought to New York. I cannot give any opinion as to the cause of the fire.

(Signed) Alphonse Côté.

(Signed) E. M. Archibald,
H.B.M. Consul General,
President.

Octave Côté, being further examined, saith: The cargo was shipped at Liverpool on account of the owners of the ship, through their agent. I am not aware of any regulations in regard to the loading cargoes of coal for long voyages, or for any voyages. About five years ago I commanded a barque in which we carried a cargo of coals from Liverpool to Havana. It was shipped in the Bramley Moore dock. Our voyage lasted about 50 days. The coals were delivered at Havana in good order. I have carried coals from Cape Breton to the West Indies, but the voyages were of short duration. In my late voyage the hold was ventilated by having off half of the fore hatch, as I have stated; sometimes, when the weather was fine, I had the quarter hatch off also. Before the discovery of fire, we did not notice any settlement of the cargo; but afterwards, we observed that the coals settled down. We considered that this was owing to the fire in the body of the coals below making more space. We had a very rough night after we took the boats, and shipped a good deal of water. We could get no rest or sleep. As far as I could judge, there must have been nearly 6 feet of water in the hold of the barque when we quitted her. She had the appearance of being waterlogged.

(Signed) Octave Côté.

(Signed) E. M. Archibald,
H.B.M. Consul General,
President.

Finding of the Court.

From the evidence in this case it appears that the "Aurelie," a wooden ship of the registered burthen of 548 tons, six years old, in good order and condition, having been recently repaired and newly coppered, took on board a cargo of bituminous coal at Liverpool about the 14th of April last. The quantity shipped was 701 tons. It was taken on board during two days, when the weather was fine and dry. The ship was not fully loaded, it being testified that she could have carried 150 tons more. The coal was loaded in bulk on the skin of the vessel, without any artificial provision for ventilating the cargo. The ship sailed from Liverpool on the 16th of April "for Barbadoes and a market," and arrived at Barbadoes on the 31st of May, having had fine and moderate weather throughout. She lay at Barbadoes for 20 days, during which time the master, after communicating with various West Indian ports, and finding no market for the coal, received orders from his owners to proceed to Montevideo, for which port the ship consequently sailed from Barbadoes on the 20th of June.

She pursued her voyage with moderate weather until the 1st August, when, owing to the effect of the trade winds, she had reached 30° 16′ W. longitude, and 16° 39′ N. latitude.

On the evening of this day, the second mate having reported that he suspected the coals to be on fire, owing to an unusual odour of gas, a hole was digged in the coals, which, at the depth of 2 feet, were found to be greatly heated.

On the following morning a rod of iron being driven down through the coals to the depth of 11 feet, was allowed to remain two hours, when, on being drawn up, the middle part of the rod was found to be red-hot. The ship was then steered for Barbadoes, and all sail made to reach, if possible, that port. Day by day the smoke and heat from the coals increased; the cabin became uninhabitable; the pitch in the deck-seams boiled, and the beams and lining of the ship below were, from the nature of the smoke, evidently burning.

Meantime the ship was kept under a press of sail, steering for Barbadoes, while the boats were provisioned and fitted for quitting her in case of necessity. When the fire was discovered on the 1st of August the master ceased pumping the ship, in order to allow the water to rise and thus possibly extinguish the fire. The hatches were for a day or two closed, but afterwards partly opened to obviate an explosion of gas. On the 7th August, at noon, the ship was pumped dry, and on subsequently sounding the well at 4 p.m., 3½ feet of water were found in it, showing that the ship's side must have been burnt through. At 5 p.m., she began to settle, there being nearly 6 feet of water in her hold, and the heat and smoke being also intolerable. The master and crew embarked in the boats and lay by the ship until 9 p.m., when she sank and went to the bottom.

Together with the master and crew in the boats was the wife of the master, in a very delicate state of health, and their little daughter two years old. They were then at a distance of more than 1,500 miles from the nearest land, and the boats keeping together were steered towards Barbadoes. After nearly four days of hardship and loss of rest they were fallen in with and rescued by the American ship "Moonlight," bound from Batavia to New York, and conveyed in that ship to this port.

In reviewing the evidence we find that, during the voyage out to Barbadoes, the vessel made not more than three-quarters-of-an-inch of water per hour, and less than that quantity per hour after leaving Barbadoes.

That the water could hardly have reached the coals, as the ship was regularly pumped. The moisture from the bilge-water would, however, be absorbed by the coals, and the only ventilation, if it can be called such, of the cargo, consisting in leaving a portion of the fore hatch open, spontaneous ignition of the coal naturally ensued, resulting in the loss of the ship. Such a result was obviously natural, when it is considered that the coal had been on board of this ship for very nearly four months, and during nearly three months of that time continuously within the tropics. If, as is usually the case in ships carrying coals on a voyage likely to extend over three months, a provision had been made for ventilating the cargo by means of wooden boxes or tubes penetrating the coals, the ignition in this case would probably have been prevented; and as this ship's cargo was not to be certainly landed at Barbadoes, but was shipped for that port "and a market," which, as it turned out, required her to proceed to the distant port of Montevideo, we are of opinion that some sufficient means of ventilating the cargo, and allowing the gases to escape, should have been supplied at the time the cargo was taken on board. It does not appear upon whom the duty of making such a provision devolved; and it was probably not taken into consideration by anyone connected with the ship or cargo. Having regard, however, to the circumstances of the loss of this ship, we deem it important that ships carrying cargoes of bituminous coal to distant ports, or on voyages likely to extend over 30 days, and especially when bound for tropical regions, should be loaded under official inspection, and subject to the compulsory adoption of such appliances for ventilating the cargo as may be best calculated to obviate the danger of spontaneous combustion.

Under the circumstances in which the master found himself placed when the coals were discovered to be on fire, we think he conducted himself with skill and courage. His determination, indeed, not to quit the ship so long as there was a possibility of bringing her to port was creditable to him, and was carried almost to the verge of rashness; for on the last two days, when the ship was excessively heated, the fire might have burst forth at any moment, wrapping the ship in flames and imperilling the lives of those on board.

(Signed) Theodore Cook,
Commander R.M. "Russia."

(Signed) W. Walker,
Master, ship "Greenock."

New York,
September 3rd, 1875.

"SENATOR," of Windsor, N.S., of 1,101 tons register, sailed from Philadelphia on the 8th June 1875, for Panama, with a cargo of coals.

Examination on Oath, instituted by Receiver of Wreck at the Port of Liverpool in pursuance of the 448th Section of the Merchant Shipping Act, 1854, 17th and 18th Victoria, cap. 104.

William Adams, being duly sworn, deposes as follows:

That he was ordinary seaman of the ship "Senator," of the port of Windsor, N.S.

That the crew consisted of 17 hands, including deponent.

That the ship had on board a cargo of coals.

That said ship had on board, in addition to the cargo aforesaid, three passengers, master's wife and two children.

That the said ship proceeded from Philadelphia.

That at the time of sailing as above the said ship was in good condition and well found. There were ventilators in each hatchway, which came up about level with the deck, but when the hatches were closed there was no ventilation.

That the said ship was bound for Panama.

That the said ship proceeded on her said intended voyage as above stated, and we had fine weather until we approached Cape Horn, and all the hatches were kept open. We had bad weather all the while we were rounding Cape Horn, and the hatches were all battened down when in the Pacific ocean. About 8 o'clock one evening I heard the ship was on fire, and went aft. A hole was made in the fore cabin on port side, and water was played down it with the force pump. All hands were on deck all night, and on the following morning the smoke disappeared. We continued, however, to send water down. In the evening of that day the smoke again came up from the ventilator in after hatch. We then poured water down through the hole in the cabin, and also through the after hatch, but the smoke continued, and two or three days afterwards ship was kept away before the wind and ultimately anchored in the Straits of Magellan in smooth water. There was then fire on the port side, and cabin was full of smoke, and we all left her in two boats as soon as possible after coming to anchor. The captain's wife died on the way up to Sandy Point, and after remaining there some time we all left by the s.s. "Liguria." At Monte Video we landed four seamen, and at Rio the first and second mates, and remainder came on to Liverpool.

That the above contents are in all respects correct and true to the best of deponent's knowledge and belief.

(Signed) William Adams.

Sworn at Liverpool this 17th day of November 1875, before me,

(Signed) W. H. Coulston,
Receiver of Wreck.

(Signed) Edmund H. Verney,
Commander R.N.

Charles De Fleury, being duly sworn, deposes as follows :---

That he was able seaman of the ship "Senator," of the port of Windsor, N.S., of the register tonnage of 1,101 tons.

That the said ship was rigged as a barque; that she was built of wood.

That the crew consisted of 17 hands, including deponent.

That said ship had on board a cargo of between 1,600 and 1,700 tons of coal shipped at Philadelphia for Panama.

That said ship had on board, in addition to the cargo aforesaid, three passengers, viz., master's wife and two children.

That said ship proceeded from Philadelphia on her intended voyage, as named below, on the 8th day of June last past.

That at the time of sailing as above the ship was in good condition and well found in every respect. Her draught of water was 21 feet. There were ventilators below the hatches, but when off Cape Horn we experienced bad weather, and the hatches were not taken off for a month.

That the said ship was bound for Panama.

That the said ship proceeded on her intended voyage as above stated and when off Cape Horn, during my watch below, a seaman was washed overboard and drowned.

That on Monday the 13th day of September, at 8 p.m., the weather variable and the wind in the westward, blowing a very strong breeze, with a heavy sea from the westward, the said ship was standing to the northward when one of the crew came forward and said the ship was on fire. Just after, the captain called all hands aft to pump water into the ship. When I went into the cabin smoke was issuing from the port quarter between the timber into the cabin, and the captain ordered the carpenter to cut a hole through the lining of the ship on the port side, through which we pumped water all night. On the morning of the 14th the smoke disappeared from the cabin, but was coming up through the ventilator in the after hatch, and we continued to throw water inside the lining of the ship where the fire was supposed to be. The smoke was confined to the after part of the ship. We drew the pump boxes to allow the water to run down through them. On the 15th we commenced to throw cargo overboard, but although we could not reach any fire some of the coals near the beams were consumed and large quantities of smoke and gas continued to ascend, so that it was difficult to work there. On the evening of the 16th the captain stood to the eastward for the Straits of Magellan. We had quite a gale of wind and we run her under topsails (the upper ones being reefed) reefed spanker and jib. About 7 a.m. on the 17th September we anchored about seven miles in the Straits of Magellan, abreast of Cape Pillar, at which time the smoke in the cabin was so dense that we could not enter. We immediately left the ship and landed near Cape Pillar, and about half an hour after she burst into a flame aft. The next day we left Cape Pillar and proceeded up the Straits, having scarcely any provisions. On the morning following the master's wife died, and on the following Saturday night we reached Sandy Point. The master, his two children, and eight of the crew came to Liverpool by the steamship "Liguria," arriving here on Saturday the 13th November about 4 p.m.

That in consequence of the casualty to the said ship two lives were lost, one washed overboard, one died from exposure, the remainder, 18, being saved by our own boats.

That the above contents are in all respects correct and true to the best of deponent's knowledge and belief.

(Signed) Charles De Fleury,
Deponent.

President.

British Consulate, Valparaiso,
6th October 1875.

Schedule of Enclosures, transmitted with letter dated 6th October 1875, from H.B.M.'s Consul at Valparaiso. President of a Naval Court held at Valparaiso on the 4th day of Ocrober 1875.

Letter.	Nature of Document.
—	Minutes of Proceedings.
A.	Orders summoning the court.
B.	Deposition of master.
C.	Deposition of first mate.
D.	Deposition of second mate.
E.	Deposition of steward.
F.	Deposition of carpenter.
G.	Deposition of the crew.
H.	Finding of the court.
I.	Extract from official log of "Foxhound."
J.	Official log of "Clevedon," containing the written statement of the master.

Minutes of Proceedings taken at a Naval Court of Inquiry held at the British Consulate, Valparaiso, on the 4th day of October 1875, to investigate the causes of the burning and abandonment of the British barque "Clevedon," official No. 60086, of Liverpool, on the 21st September 1875.

Present :

President :

James de Vismes Drummond Hay, C.B., Her Brittanic Majesty's Consul.

Members :

Lieutenant John Deane Deane, of Her Majesty's ship "Tenedos."

Mr. William Harris.
Master of barque "Maida," of London.

Clerk of the Court :

Mr. Thomas Owen Joynson, Paymaster of H.M.S. "Tenedos."

The master of the barque "Clevedon," David Hughes, with the first mate, second mate, carpenter, and 11 men lately forming the crew of the vessel, and named severally :

William Royce, first mate.
James Barnes, A.B.
Frederick Broom, ordinary.
Henry Boyes, second mate.
Frederick Henrickson, A.B.
A. W. Hignett, apprentice.
Benjamin Ouset, carpenter.
James Hands, A.B.
Charles Maughan, steward.
Angus Sutherland, A.B.
John Hartgreaves, sailmaker.
Joseph Dromedius, A.B.
William Morgan, A.B.
Edward Jacobson, A.B.

Absent :

Nicholas Demetrius, A.B.
Herbert Morley, A.B.
Walter Gilbert, ordinary.

Order summoning the court read in the presence of all the witnesses and the members of the court and clerk of the court sworn in.

Witnesses were then ordered to retire from the Court, except the first, David Hughes, master, whose certificate of competency, No. 88,378, was laid on the table, as also those of William Royce, first mate, No. 96,187, and Henry Boyes, second mate, No. 26,557.

David Hughes, being called on by the court to make a statement of how the burning and abandonment of the vessel occurred, laid before the court a written statement, contained in the official log book, which was read and signed by deponent, the first and second mates, sailmaker, and a number of the crew, and ordered to be annexed to the proceedings, and is marked J. ex J.

David Hughes was then examined, and in answer to questions put by the court replied as put down in the annexed deposition marked B. ex B.

An extract from the official log of the British barque "Foxhound," of Swansea, official No. 58090, duly signed by James Halliday, the master, and John Evans, mate, was read and ordered to be annexed to the proceedings, and is marked J. ex J.

William Royce, first mate of the barque "Clevedon," was next called before the court, and in presence of the master was examined, and stated as set down in deposition marked C. ex C.

Henry Boyes, second mate of the barque "Clevedon," was next called and in presence of the master was examined, and stated as set down in deposition marked D. ex D.

Charles Maughan, steward of the barque "Clevedon," was next called before the court, and in the presence of the master was examined, and stated as set down in deposition marked E. ex E.

Benjamin Ouset, carpenter of the barque "Clevedon," was next called before the court, and in the presence of the master was examined in French by the president, and stated as set down in deposition marked F. ex F.

The members of the crew, and named severally—

John Hartgreaves, sailmaker,
William Morgan, A.B.,
James Barnes, A.B.,
Frederick Henrickson, A.B.,
James Hands, A.B.,
Angus Sutherland, A.B.,
Joseph Dromedius, A.B.,
Edward Jacobson, A.B.,
Frederick Broom, ordinary,
A. W. Hignett, apprentice,
Herbert Morley, A.B.,
Walter Gilbert, ordinary,

were then called together before the court and examined in the presence of the master, and deposed as set down in annexed deposition marked G. ex G.

The court was then cleared, and the members proceeded to deliberate and frame their opinion and finding, which was written out, and, being duly signed, is annexed to the proceedings and marked H. ex H.

The court was then re-opened, and the finding of the court was read over in the presence of the master, mates, and crew of the late barque "Clevedon."

The certificates of the master, as also of the first and second mates, were returned to them.

The court was then closed, and the proceedings terminated at 5.30 p.m.

(Signed) J. de V. Drummond Hay,
H.M. Consul and President.

Annex A.

By Edwin John Pollard, Esq., captain of Her Majesty's ship "Tenedos," senior naval officer present at Valparaiso, being the officer empowered to order naval court by the Merchant Shipping Act, 1854.

To

James de Vismes Drummond Hay, C.B., Her Majesty's Consul at Valparaiso, as pres
John Deane Deane, Esq., lieutenant of Her Majesty's ship "Tenedos;"
William Harris, Esq., master of the British ship "Maida;" as members.

Whereas the master and 17 men belonging to the British barque "Clevedon," of Liverpool, official No. 60086, have arrived at Valparaiso, and have reported that the said vessel was burnt and abandoned at sea on the 21st September last:

And whereas I consider it requisite that a naval court should investigate the cause of said loss and abandonment: I do hereby order and direct you to assemble together to form a naval court at the British Consulate on the 4th day of October 1875, to inquire into the causes of the loss and abandonment of the aforesaid vessel, such court being hereby ordered to investigate the same.

Given on board Her Majesty's ship "Tenedos" at Valparaiso this 2nd day of October 1875.

(Signed) E. J. Pollard,
Captain and Senior Officer.

Annex B.

Examination of David Hughes, Master of the late Barque "Clevedon," of Liverpool, official No. 60086.

A written statement of the occurence being annexed to the proceedings, deponent, in answer to questions put by the court, replied as follows:—

The ship was seven years old, and classed as A1 at Lloyd's, and is iron, 698 tons. The crew consisted of 18 men, all told. The cargo consisted of steam coal. The fire was first discovered on the morning of the 20th September 1875, in lat. 41° 52′ S., long. 78° 33′ W. Had two pumps on board, both in good order. The ship was well found in everything. The ship was ventilated by a ventilator on the quarter deck, and one on the house forward, and one on main deck into chain lockers. The coal was shipped at Liverpool by F. A. Widdows & Co. The chief mate received the cargo. I saw about 300 tons passed on board, and what I saw was dry and in good condition. I am unable to account for the fire. Had one tin of paraffin oil on board; it was stowed in the oil locker on deck; at commencement of the voyage it was there, but subsequently it was condemned as unfit for use, and stowed away in the store-room. This can was examined after the smell of fire was discovered, and found to be perfect without leakage.

(Signed) David Hughes,
Master.

Before me,
(Signed) J. de V. Drummond Hay,
Consul and President.

Annex C.

Deposition of William Royce, first mate of the barque "Clevedon," holding a certificate of competency, No. 96,187, as first mate.

This is my first voyage as first mate. The coal was received in dock; the latter portion seemed to be larger coal than that first received. I did not notice any portion of the coal being wet. It appeared to me all dry. The weather was fine and it did not rain. The vessel was trimmed in general from 2 to 4 feet from the main deck. The fore and aft hatches were taken off whenever we had fine weather. The vessel was also ventilated by three or more ventilators. When we first perceived the smell of fire it was suspected that the steward might have upset some paraffin oil, but on examination of the lazarette the can was found untouched, and showed no sign of leakage. There was one 10-gallon can on board. Over the fore hatch there was no smell, nor was the coal hot. The after hatch the same. In the cabin there was a slight smell. We had had heavy weather and the ship had taken in some water. Two days after the smell, the smoke came out of the foremost ventilator. The foremost hatch was taken up, the smoke was so great that it was battened down again; the same with the after hatch. Had no knowledge how long the coal had been in the lighters before shipment. I am of opinion that the vessel was not left too soon. The decks were blown up by the main and after hatches. From the time we first saw the smoke the boats were got ready on deck, and afterwards all hands were employed endeavouring to smother the fire with water. After going on board the "Foxhound," the vessel which saved us, I returned to the "Clevedon" at the master's wish, in order to see what I could save. I entered the vessel by the stern, but could not go further than the companion, the fire was so great. The last I saw of the "Clevedon" the main and mizen masts had gone overboard. The seat of the fire appeared to be on the port side of the main hatch, that is where I believe it originated, amongst the small coal.

In answer to question by master, witness deposed—

I believe the master did ask the steward whether he had been using paraffin oil; I think his answer was that he had not, as some time before he found he could not use the paraffin oil and used colza oil instead.

(Signed) William Royce,
First Mate.

Before me,
(Signed) J. de V. Drummond Hay,
Consul and President.

Annex D.

Deposition of Henry Boyes, second mate of the barque "Clevedon," holding a certificate of competency, No. 26,557, as second mate.

This is my first voyage in this ship, and my first with the master, Mr. Hughes.

When I joined, a portion of the cargo was on board. I assisted in trimming a great portion of it below. It appeared to me to be dry. The large and small coal mixed. I know not the difference of steam coal and other coal at sight, but the cargo seemed to me to be all of one class. The first suspicion of fire was caused by a strong smell which seemed to be of paraffin oil, and search was made. The smell was perceived in the cabin and not in the fore part of the ship. This occurred on a Saturday, and on the Monday following we saw smoke and first became convinced of a fire on board. The hatches were battened down, and about two or three hours afterwards blew up, the main hatch going first, and through that hatch water was bucketed down. I do not think the vessel was abandoned too soon. I can give no opinion as to the cause of the fire, and have no suspicion of any foul play. The coal extended underneath the cabin deck. I went down on Saturday, the day of the smell, and examined that part of the cargo, but perceived nothing.

The smell was first perceived by the first mate, myself, and steward on the companion; the lazarette was further aft, below the after cabin where we had our breakfast, and where I had not smelt a smell.

(Signed) Henry Boyes,
Second Mate.

Before me,
(Signed) J. de V. Drummond Hay,
Consul and President.

Annex E.

Deposition of Charles Maughan, steward of the barque "Clevedon;" being duly sworn, stated as follows:—

I belong to Weymouth and have been 32 years at sea; am 48 years of age. It is my first voyage with Mr. Hughes. I did not know the master before I joined the vessel. The stores of the ship were all in my charge. We had paraffin oil and colza oil on board for the lamps. I used the paraffin oil at first, but not burning properly, with the consent of the captain I used only colza. The can with the paraffin was stowed away in the lazarette and I had no occasion to touch it again, except once, and that was before we rounded the Horn, in order to get a little for the carpenter's use. When we perceived the smell on the 18th September, being afraid that the paraffin can might have been capsized, I went down to the lazarette, but found that notwithstanding the knocking about of the vessel, the can had not been upset and was tightly corked. I can form no opinion as to the cause of the fire except that it originated in the coals. I think the master quite right in having abandoned the vessel. I have no suspicion of foul play. The decks were burnt and blown up in three places before we left.

(Signed) Charles Maughan,
Steward.

Annex F.

Deposition of Benjamin Ouset, carpenter of the barque "Clevedon;" being duly sworn, stated as follows:

I joined the "Clevedon" at Liverpool. I am a native of France. On Saturday the 18th September the hatches were closed. On Monday morning the mate called me hurriedly to bring a hammer to open the hatches. On opening the hatches a great volume of smoke came out and the hatches were again closed. It was my duty every morning to oil and clean the worms or screw of the wheel. I used olive oil—I call it so, for so it was called to me, but you will understand I did not taste it. It was given to me by the first mate out of a tin can in the oil locker on deck near my berth. The oil for paint was kept in other cans, and larger, in the same locker. At one time when near or off the Horn I tried paraffin oil to clean the stays of the worm, I used it for several days. I got it from the steward who went down with me to the lazarette for it, and he gave me about half a pint; I used it for 8 or 10 days, but finding it was not good I told the captain of it, and at his desire I used lamp oil. When on the Friday previous to the fire I had, as usual on a fine day, opened the hatches, I did perceive a slight smell such as of petroleum, but very slight. I can form no opinion as to the cause of the fire; but with reference to the suspicion of the paraffin, I must say that it could not have caused the fire, for the following reasons. The seat of the fire was on the port side of the main hatch, between that portion of the ship and the main hatch there is a bulkhead partly of iron.

When I had battened the hatches and secured the ventilation tightly I kept a watch on the beams of the deck, and it is my opinion that the fire commenced in the upper portion of the cargo, for not only did I notice the deck bulging on the port side between the main hatch and the kitchen, and the pitch in the seams, melting, but when told by the captain to bore holes in the deck to let water through, I found the planks, which were originally 4 inches thick, to be burnt to the thinness of 1½ to 2 inches proving that the fire was on the surface of the cargo. The pumps of the ship sucked, but not freely, at 4½ inches. I consider the vessel had always 4½ inches in her. There were 18 inches between the keel and the ceiling in depth.

The ship was not abandoned until the fire had completely got possession of her. I had secured my tools, and, by the good fortune of the vessel which saved us, was enabled to save them. I lost some of my clothes, but saved my tools.

(Signed) Benjamin Ouset,
Carpenter.

Consul and President.

Annex G.

Depositions given by the Members of the Crew named severally, as follows:—

John Hartgreaves, sailmaker,
William Morgan, A.B.,
James Barnes, A.B.,
Fredk. Henrickson, A.B.,
James Hands, A.B.,
Angus Sutherland, A.B.,
Joseph Dromedius, A.B.,
Edward Jacobson, A.B.,
Fredk. Broom, A.B.,
A. W. Hignett, Apprentice,
Herbert Morley, A.B.,
Walter Gilbert, Ordinary;

who did severally and together declare that they had no complaint to make; that they had no suspicion as to the cause of the fire, beyond its being caused by the coal; that the master did not leave the vessel until the fire had rendered it impossible to remain any longer in her; that they saved little or nothing of their clothes; that the master exerted himself in preparing and provisioning the boats; and that they were fortunately saved by the "Foxhound," on board of which vessel they were well treated until their arrival at Valparaiso.

Before me,

Master.
" John Evans,
Mate.

Septr. 21, 1875, 4.30 a.m.,
Lat. 40° 10′ South, Long. 77° 00′ W.

Made out a vessel to windward burning blue lights. I then hauled my ship to the wind and came to within hailing distance, when the said vessel proved to be the "Clevedon," of Liverpool, with cargo on fire, and the master asked me to lay by him, which I did until daylight, when I saw volumes of smoke and flame ascending from the hatchways, and the fire seeming to increase very rapidly. At 7 a.m. the master and crew came on board my ship in their boats. I then bore away and passed close under her stern and saw that her main deck was in a blaze. After the chief mate and four hands revisiting the ship, and seeing that nothing further could be done, and shortly afterwards seeing the main and mizen masts fall over the side, I then made sail and proceeded on my course as nothing more could be done.

Annex H.

Finding of the Court.

At a naval court of inquiry assembled at the British Consulate, Valparaiso, on the 4th day of October 1875.

Present:

President.

James de Vismes Drummond Hay, C.B., Her Britannic Majesty's Consul.

Members.

Lieutenant John Dean Deane, of Her Majesty's Ship "Tenedos."

Mr. William Harris, Master of Barque "Maida"

Clerk to the Court.

Mr. Thomas Owen Joynson, Paymaster H.M.S. "Tenedos."

The court, pursuant to an order from Edwin John Pollard, Esquire, captain of Her Majesty's ship "Tenedos," and senior naval officer present at Valparaiso, proceeded to investigate the circumstances attending the burning and abandonment of the British barque "Clevedon," of Liverpool, Official No. 60086. And having deliberately weighed and considered the evidence and observations preferred by the master and the men, late members of that crew, who have appeared before the court: The court is of opinion that the statement made by the master of the barque "Clevedon," that the vessel was abandoned on fire at sea, is correct. That such fire had its origin in the spontaneous combustion of the coal. That the master, Mr. Hughes, his officers and crew, appear to have performed their duty to the utmost of their power to save the vessel; and that no blame can be to them attached for the casualty.

The court, therefore, has much pleasure in returning to the said master his certificate, as also to the first and second mates their certificates.

Further the court desire to express their opinion that had the "Clevedon" been supplied with force pumps or other appliances for extinguishing a fire, there might have been a greater chance of preserving the vessel, and that the provision of such appliances should be obligatory on all vessels.

(Signed) Wm. Harris.
" John D. Deane.
" J. de V. Drummond Hay.
(Signed) Thos. Joynson,
Clerk to the Court.

"RIVER BOYNE," barque of Liverpool, iron ship of 498 tons register, eight years old, classed A1 Lloyd's.

From the Wreck Report it appears that she sailed from Liverpool on the 15th July 1875, for Valparaiso, with 776 tons of coal.

No means of ventilation beyond keeping the hatches off.

Part of the cargo burnt owing to spontaneous combustion on October 12th, 1875, part of cargo (about 60 tons) thrown overboard, put back to False Cape Horn, when vessel was anchored; but finding fire could not be extinguished, master put the vessel close in shore and scuttled her by letting in water through decks, extinguished fire, raised the vessel and proceeded on voyage; arriving at Valparaiso on 27th November, where cargo has been sold and vessel undergone slight repairs.

A protest was received from H.B.M. Consul at Valparaiso by the Board of Trade, who forwarded to the Commission the following extract:—

Extract from the Protest of the British Barque "River Boyne," of Liverpool, Official No. 55,054.

That on the 15th of July they, the said appearers, left Liverpool in and with the said barque "River Boyne," laden with a cargo of coals and bound to this port of Valparaiso. That nothing worthy of note occurred until the 8th of October, from which date they experienced heavy weather, and the vessel laboured and rolled, shipping much water. That from the 8th October the hatches had been kept closed, on account of the heavy weather, until the 12th October, when they removed the fore hatch and found smoke issuing from the hold.

That all hands were set to work to extinguish the fire, and for that purpose they were obliged to throw overboard a portion of the cargo for the benefit of all concerned. That in spite of their endeavours the fire increased rapidly, and on the 13th October they deemed it prudent to run for an anchorage. That they accordingly battened down all the hatches and made for the land. That the smoke continued to issue in volumes from under the tarpaulins. That at 1.30 p.m. on the 14th October they arrived in a small bay near False Cape Horn. That they anchored the vessel fore and aft, and immediately took measures to extinguish the fire by making holes in the decks, flooding them with water, and pumping down the hold. That at 5 p.m. there were 7 inches of water in the hold. That at 8 p.m. the crew refused to continue working, complaining of want of rest. That the officers and carpenter continued flooding the hold until 4 a.m. on the following morning, and at 5 a.m. all hands again turned to. That the fire increased, and their efforts were unavailing. That at 6 p.m. there were 5 ft. 6 ins. of water in the hold. That during the night all hands were divided into two watches, and the head pump and main pumps were kept going, and the decks were kept flooded with water. That the cabin and forecastle were so full of smoke that all hands had to remain on deck. That at 6 a.m. on the 16th October there were 6 feet of water in the hold. That they took off the after hatch, and finding very little smoke they proceeded to dig the coals out to trim the ship more by the head, and also in order to get at the fire, which appeared to be on the fore side of the main hatch. That they threw overboard about 30 tons of coal for the benefit of all concerned. That at 4 p.m. the smoke drove the men from below and constrained them to close the hatch, and although the coal was quite cool as far as they had dug, the fire increased rapidly. That they did not cease flooding the coal, and at 8 a.m. on the 17th October there were 8 ft. 10 ins. of water in the hold, and the ship was down to the hawse pipes and scuppers in the water. That they removed the main hatch, but found the smoke denser than ever, and they were constrained to batten it down again. That after due consultation with his officers the master determined, for the safety of the ship and cargo, and the interests of all concerned therein, to scuttle the vessel. That after examining the shore and putting the vessel in position they beached the ship on the W.N.W. side of the bay, abreast of a stream of water, on a smooth sandy bottom, void of rocks. That they then proceeded to scuttle the ship by letting the water into the forecastle through the side lights, and the carpenter drove rivets out of the bulkhead of the fore compartment to assist the sluices in flooding the hold. That at noon the tide fell and left the vessel laying quiet and quite upright on the sand. That at 4 p.m. the tide rose and filled the vessel to 13 feet. That the smoke continued issuing from below, and all were kept at work flooding the decks. That they experienced hard gales of wind, but that the bay was perfectly sheltered from the heavy sea. That at 6 a.m on the 18th October the tide rose and filled the ship fore and aft, covering the main deck as far as the fore part of the main hatch. That there were 3 feet of water in the cabin, the coals being completely covered and the fire extinguished. That at 8 a.m. the tide fell clear of the hawse pipes and scuppers and all hands were employed at the pumps and the carpenter proceeded to plug up the hawse pipes and every aperture in the bulwarks and decks. That the wind continued to blow a strong gale from the S.W. That at 6 p.m. it was high tide and the water rose just above the hawse pipes but none entered the vessel. That the pumps were kept going all night. That at 6.30 a.m. on the 19th October the tide rose high and completely filled the vessel again. That at 9 a.m. the tide fell and the men returned to the pumps. That the weather continued boisterous. That at 6.30 a.m. on the 20th October the tide rose and flooded the vessel's decks again, but little or no water entered the hold. That they lightened the vessel by throwing cargo overboard into the sea out of the main hatch, for the benefit of all concerned, and that the pumps were kept constantly at work. That they got the tow line out and endeavoured to bend it, but were unable to do so on account of the strong gale, which also prevented them from pumping that night. That at 5 a.m. on the 21st October the pumps were again set at work. That at 7 a.m. the tide rose to the scuppers. That they ran out the tow line and 15 fathoms of chain, and shackled it on to the outlying cable which had been slipped. That at midnight the weather moderated. That there were 10 feet of water in the well, and at 6 a.m. on the 22nd October there were 8 feet of water in the hold. That at 7.30 a.m. the ship floated without any perceptible motion. That the weather was fine and moderate. That they hove on the tow line and got the ship out to her former position in 6 fathoms of water, with 60 fathoms on the port cable and 25 fathoms on the starboard cable, the ship being by the head, and the hawse pipes just clear of the water. That the pumps were kept constantly at work. That during the time the vessel was aground the lowest water round the ship was 10 ft. 8 ins. That at noon there was 1 ft. 9 ins. of water in the well. That the vessel did not leak. That at 6 a.m. on the 24th October they trimmed the coals from forward to the after part of the ship, and bailed out the fore compartment, the sluice being choked. That the water in the tanks was rendered useless, and had to be renewed from shore. That the pumps were kept constantly at work, and at 8 p.m. there were 7 inches in the well, which they pumped out. That at 6 a.m. on the 25th of October they continued trimming the ship. That they bailed the fore peak dry, and otherwise proceeded to get the vessel ready for sea. That at 7.30 p.m. they found 10 inches of water in the well, and pumped it out. That they continued making the ship ready to sail. That at 10 a.m. on the 26th October the American schooner "Golden West," of New London, came into the bay and anchored for an hour in order to offer assistance to the "River Boyne." That they weighed the stock of bread, and found there were 450 pounds fit for use left. That all the ship's provisions were more or less damaged, and a great portion of them was entirely destroyed by the salt water. That they prepared everything in order to set sail the first opportunity. That the weather continued boisterous until the following day, the 29th October, when they proceeded on the voyage. That the total amount of cargo thrown overboard was about 60 tons. That nothing further worthy of note occurred, and they arrived and anchored in this port of Valparaiso on the 27th day of November, on which day a survey was called on the condition of the vessel and cargo, and the instructions of the surveyors are now being carried out.

"LE BARON" of Liverpool, wooden vessel, 889 tons register, 6 years old.

From the Wreck Report it appears that she sailed from Hull on the 16th August 1875 for Valparaiso, with 1,378 tons of coal.

Was burnt at sea about 30 miles north of Cape Horn, owing to spontaneous combustion of coal cargo.

"BEUCLEUCH" of Alloa, iron ship of 1,350 tons register, 1 year old, classed A1 Lloyds'.

From the Wreck Report it appears that the "Beucleuch" sailed from Greenock the 18th August 1875, for Bombay, with 1,781 tons of coal.

Ventilated by means of four patent ventilators and usual hatches.

Partial lost of cargo and damage to vessel caused by spontaneous combustion of coals. On the 22nd November, in lat. 8° N., long 68° E., smoke and gas were observed to be issuing from the foremost part of the main hatch. The steam fire engines were set on and for four days played down the ventilator.

The hatches were then battened down, the hose continuing to play into the hold. After four hours the hatches were removed, the gas appearing to have greatly accumulated; coal was discharged from main hatch to the fore and after hatches until they were full. A large amount of water having been pumped below, about 200 tons of cargo was jettisoned from between decks. On the fourth day, the fire increasing, all hands were compelled to withdraw from the main hatch. Four rivets were now driven out from under water line to save the ship, there being at the time 7 feet water in the hold. At about 4 a.m. next day the water had increased in the hold to 10 feet, and the fire was extinguished. The holes were then stopped, sluices shut, pumps set on, and at 5 p.m. on the 27th November the pumps sucked. Trimmed ship upright, she had taken a slight list on transferring the coal, and resumed voyage, arriving safely at Bombay on the 5th December last.

"SAN RAFAEL" of Liverpool, wooden ship of 955 tons register, about 13 years old, re-classed at American Lloyds' A1 in September 1875.

From the Wreck Report it appears that she sailed from Liverpool the 18th September 1875, for Valparaiso, with 1,300 tons of coal.

Was ventilated by means of a ventilator in each hatch.

The vessel had arrived in the above-mentioned latitude and longitude all well. The second mate was in charge with the starboard watch on the morning of the 2nd January last. At 7 a.m. the sailmaker called the chief officer and stated that smoke was issuing from the forehatch, the second mate having been below previously for some lashings. The master was called, and after consultation the hatch was replaced and the vessel continued her course. At noon smoke was observed issuing from the after-hatch ventilator. The hatch was removed and the cargo found to be on fire. All hatches were now immediately battened down and the vessel was put about to return to the Falkland Isles. At about 10 p.m. on the 3rd January she had run back about 260 miles when an explosion suddenly occurred, blowing off the main and after hatches and displacing the bulkhead in the cabin. A part of the crew were now directed to prepare the boat, the remainder directed to the fire engine, and a large quantity of water was thrown down upon the cargo, but without avail. At about 10.30 p.m. a second explosion occurred and flames burst up the hatchways. The boats were got out and provisioned, explosions occurring from time to time. At 4 a.m. the 4th January, there being an immense body of fire in the vessel, it was determined to abandon her, the master, the master's wife, the carpenter, four A.B. seamen, and three apprentices got into the longboat. The first mate, cook, steward, sailmaker, and three A.B.'s got into the lifeboat. The second mate, the third mate, two A.B.'s and an apprentice got into the gig. The boats remained by the vessel until 8 a.m., when the weather freshening it was deemed advisable to pull to land. After about four hours the longboat got separated from the two other boats and has not since been heard of. At 2 a.m. on the 5th January the lifeboat and gig arrived at a small uninhabited island inside the Isle d'Alfonso, where water and shellfish were procured. The boats proceeded to sea, returning from time to time to the island for shelter in bad weather, searching along the coast for the longboat, and on the lookout for passing vessels. After 20 days the cook succumbed from exhaustion and was buried on the island. Seven days later, on the 31st January, the lifeboat and gig being at the time about 20 miles S. of Diego Ramirez Islands, a ship which proved to be the "Yorkshire" hove in sight and was signalled. She bore down and the hands from the two boats, 11 in number, got safely aboard. They were treated with great humanity and kindness by all on board the "Yorkshire," and arrived safely in London at 2 a.m. this day. The casualty appears to have been caused by spontaneous combustion.

"THERESA" of London, wooden ship, of 705 tons register, 18 years old, classed at French Lloyds' 5/5 1–6–5 years.

From the wreck return it appears that she sailed from Liverpool on the 25th September 1875, for Rangoon, with 920 tons of coals.

The ventilation, as described by the master, appears to have been complete.

Burnt at sea, about 70 miles west of Cape of Good Hope, by spontaneous combustion of cargo of coals.

"FANNY," barque, of Sunderland, 397 tons register.

Sailed from Swansea, bound to Valparaiso, with a cargo of coals.

When off Valparaiso, on 23rd December 1875, was found to be on fire from spontaneous combustion of cargo; she put into Coquimbo, where with assistance from H.M.S. "Nereus" the fire was got under and the cargo discharged, when she was found much burnt on starboard side by main rigging planks being nearly burnt through, in places to ⅓rd of an inch; was repaired, and left Coquimbo 9th April.

The following letter, received by the Board of Trade from Her Majesty's Consul at Coquimbo, relative to the cases of the "Mabel" and "Fanny," has been received by the Royal Commission from the Board of Trade:—

British Consulate,
Coquimbo, 4th May 1876.

SIR,

I HAVE the honour to enclose Vice-Consul Mark's report on the accident to the 'Mabel,' of Bristol, by fire at Caldera in December last.

"On 31st December and 13th April last, I reported the 'Fanny' O. N. 47667, which put in here on fire, which was extinguished, the vessel repaired, and sailed on 9th ultimo.

"It is worthy of remark that both vessels loaded at Porthcawl, Swansea, both bound for Valparaiso.

"The 'Mabel' arrived and remained a day or two, and the day she left for Caldera to discharge, the fire was discovered; the cargo of the 'Fanny' was discovered to be on fire when in sight of Valparaiso.

"I venture to suggest, from what I have experienced and heard, that if iron bars were placed vertically in different parts of the coal they would tend to throw off the heat, or at least serve as thermometers or guides to find out where the fire is."

I have, &c.
J. Grierson,
H.B.M. Consul.

The following Reports of Statutory Inquiries held by the Board of Trade into cases of Gas Explosions on board Coal-laden Vessels since 1868 have been forwarded by the Board of Trade to the Royal Commission for inquiring into Causes of Spontaneous Combustion of Coal in Ships.

THE "ZENO."

Board of Trade Inquiry into the total loss of the "Zeno," held at the Police Court, Borough of Kingston-upon-Hull, 11th June 1873.

Before Walter Wrangham, Esq., Police Magistrate.
Captain White, R.N.
William Darley, Esq., Naval Architect.

Mr. Saxellye appeared on behalf of the Board of Trade.

Mr. John Hearfield appeared for the owners, Messrs. Thomas Wilson, Sons, and Company, and the Master, Edwin Owen.

The Master's and Chief Officers certificates were handed in.

Official number of ship, 65252. No., date, and port of registry, $\frac{72}{1871}$, Hull; screw. Built at Hull in 1871 by Earle's Shipbuilding and Engineering Company, Limited, Hull. One deck and poop; two masts, brig rigged; Clench built; length, from fore part of stem to aft side of head of stern post, 272 ft. 6 tenths; depth in hold, from tonnage deck to ceiling, 17 ft. 7 tenths; gross tonnage, 1,490·21; registered tonnage, 1,163·96.

Thomas Booth, of 14, Brook Street, Hull, late second mate of the S.S. "Zeno." I joined the ship in November 1872. In December last I was promoted to be second mate, and was second mate at the time of the accident. I believe the ship was a first-class ship; hailed from Hull; was manned by 29 or 30 hands, all told; she was brig-rigged. She carried six boats—two lifeboats, two large boats carried on the bridge, a gig, and a jolly boat. In the early part of May last the vessel was in the Penarth Dock at Cardiff where we took in a cargo of coals about 1,900 or 2,000 tons. I believe they were steam coals. We completed the loading at 1 a.m. on the 10th of May 1873. We got out of dock between 4 and 5 p.m. on the same Saturday afternoon, there being then a dense fog at the time. We went into the Penarth Roads, and laid there until Sunday morning. I believe we got under weigh about 3 a.m. The vessel proceeded slowly in consequence of the fog. The fog continued until the Monday afternoon. At 6 a.m. on the 12th May the vessel was stopped to take soundings, and the course was then shaped to Cape Finisterre. When the fog cleared away and we proceeded at full speed. We had some sail set, and it was so set until the morning of Tuesday, the 13th May, when the accident occurred. At 8 a.m. on the 13th May (Tuesday) I was relieved by the chief mate, the weather being fine, going at full spead, and being under steam and sail. I went below, had my breakfast, and went to my berth; was reading in my berth, which is down below amidships, against the entrance of the saloon. The vessel is divided into compartments: No. 1 was the forehold; before that was the peak—it was divided from the forehold by a water-tight iron bulkhead. The main hold was No. 2, and was divided in the centre by a wooden bulkhead. The aft part of the mainhold is called No. 3, and that is divided from the engine-room by an iron bulkhead and the engine-room is divided from the after hold, which is called No. 4, by an iron bulkhead. The holds were ventilated by the hatches. No. 3 was ventilated by opening the hatches on Monday. The trimmers went down to trim the coals; no lights were taken down, there was sufficient light from the opening. The other hatches were closed on the Sunday, battened down with canvas in the usual manner, and continued so until the time of the accident. No. 1 was battened down the last. We have printed rules on board the vessel, issued by Messrs. Wilson. Rules produced marked "B" are the rules. I have looked at them, but not carefully. They were in the mate's cabin for me to look at if I was so minded. I have seen two copies of the rules on board the ship. I have never heard the rules read over by the captain or chief officer; they may have been. The crew had access to the rules if they chose to ask to see them. I was aware of rule at p. 13 as to naked lights.

While I was reading in my berth as before mentioned, about 9.15 a.m., I heard an explosion in the vessel. There was a tremulous motion, accompanied by a dull rumbling sound. I went on deck forward. I saw that four of the iron hatches of the No. 1 hatchway had been blown away; the remaining or fifth hatch being then laid on the port side of the vessel. There was a derrick boom which was 10 feet above the deck; it had been broken in two pieces. The fore topsail and the stay foresail were both shivered, holes blown into them. I went to the captain to hear what were the orders. He ordered us to get some of the boats ready, and we got three boats ready, and while the men were getting the boats out he ordered other men to get a sail out. I mean by getting the boats out, swinging them over the side, and lowering them to within 3 or 4 feet of the water, so as to be ready. The sail was to be put over the port bow to see if it would stop the water coming in. I had previously looked into the hold, and saw a large hole had been made in the bulkhead between the peak and No. 1 hold. I saw Bennington, a seaman, on board on deck. He was very much injured, burnt black in face, head, and hands. All attempts failed to keep the vessel afloat. We got into the boats. There were two steamers in sight, the "Cairo" and the "Brighton." The "Cairo" was outward bound, and the "Brighton" homeward bound. The enginemen were first put on board the "Cairo." They were subsequently transferred and all hands to the "Brighton," and we were all taken to Liverpool, where we arrived on Friday the 16th day of May. A quarter of an hour after we left the "Zeno" she went down head foremost in deep water in the Bay of Biscay, in about 40 minutes after the accident. Independent of the accident which happened to three or four of the men all the crew were saved. We had on board the usual signal and cargo and hold lamps. The cargo lamps had glass round, and vent holes at the top. They were not what we call naked lights. The cargo lamps were used by the labourers in taking in and discharging cargo. In addition to these we had two or three lanterns, and there were several lamps that had no frame to them, naked lamps, spirit lamps. These lamps (spirit lamps) were used in the engine-room; in the bunkers for trimming, and one in each forecastle—firemen's and seamen. It is common to use that description of lamp in all steamers that I have gone in. These lamps are usually hung up in the forecastle at night. I have been in four steamers, and they have been used in all. When we were loading the vessel at Cardiff candles were used. The trimmers required candles to be used. The trimmers formed no part of the crew. The accident happened in the store room, which is immediately under the forecastle in the bow of the vessel. I have been on board vessels laden with coals several times before, and never knew an accident happen of that description. I have never been on board a vessel laden with Cardiff coals. It has not been usual to take off hatches in vessels I have been in before laden with coals. I have known the hatches remain on, I can say with certainty, for a month.

Cross-examined by Mr. Hearfield.

I have been at sea between five and six years, and have been in ships before the "Zeno," but never in a finer ship. She was well found in every respect. I think it was not possible to suggest any improvement in her. I have sailed with Captain Owen since I joined the "Zeno" in November last. The captain is exceedingly attentive and careful. The ship was clear of the Bristol Channel out at sea when the hatches were battened down. I have never seen the rules of the Penarth Harbour, Dock, and Railway. I find the rules now produced marked E contain a rule, No. 18, as follows:—"The hatches of every vessel laden with coal " must be left open during the whole of the time such " vessel stays in the dock, basin, or harbour, and must not " be closed until such vessel has passed through the sea " gates, or from the harbour on her way to the channel." I say, considering that rule, that the hatches are to be closed after leaving. As a seamen, I know it is necessary to close the hatches as soon as a vessel leaves port. As a rule it would not be safe to proceed to sea without doing so; it would depend upon the weather. As a rule it is rough in the Bay of Biscay. I should close the hatches going into the Bay of Biscay. I consider it to be the duty of the chief officer, mine, and the carpenter's, to see to the closing of the hatches, and the ventilation of the cargo. The vessel left Cardiff on the Sunday, and it continued foggy until the Monday afternoon. It requires constant supervision on the part of the master in a fog in the English Channel. The naked light was in the store room. I consider the rules specially made to provide against fire. In my opinion it would require a "Davy" lamp to provide against an explosion. Sailors could not be got to use a Davy lamp; they will hardly use lamps. We have fires in the forecastle. I don't see why they should not be as dangerous as lamps and candles. At the time the vessel blew up I had no reason to believe there was any escape of gas in the vessel. I was not aware that Cardiff coals had any special liability to emit gas. After the explosion happened the captain did everything possible to save the vessel. After the explosion I saw partly the nature of the injury done to the hull of the vessel. The hull was specially damaged in the forepart, near the stem in the port bow. I saw several rivet holes in the side of the ship.

Re-examined by Mr. Saxellye.

The forepeak is separate from the hold by being divided from it by a water-tight iron bulkhead.

(*By Mr. Darley.*) There was a sluice-valve in the forepeak. I don't know whether it was closed; as a rule it is open. I know there is something to let the water out. I know of no means by which the gas could get into the forepeak. I believe the bulkhead to be perfectly water-tight.

(*By Mr. Wrangham.*) I do not know of any orders having been given to take special precautions on account of this cargo of coals on this voyage.

(*By Captain White.*) I hold a second mate's certificate of competency since 13th August 1872. The crew of the ship consisted of a master, three mates, carpenter, boatswain, lamp trimmer, three engineers, seven firemen, steward, mess-room steward, donkey-man, cook, and eight seamen. When we took coals in at Cardiff he, the captain, was mostly on board superintending the loading of the ship. The coals were put on board by a spout. It took from the Wednesday afternoon to the Saturday morning to put the coals in. There were stoppages, of course. The coal that was in the forehold was, I believe, not put in at one time. I should think there would be from 150 to 200 tons of coal in the forehold. There was a space of 8 or 9 feet between the top of the coal and the deck in the forehold. You could walk along the top comfortably. Besides trying to get the sail over the bows, three or four of the hatches of the main hold were lifted, and we started to throw coals over the side of the ship to lighten her. When we found it was no good, the main hatches were battened down again. I never noticed any damage to the partition between the forehold No. 1 and No. 2. If that partition had been in good order I do not think it would have saved the ship. I know of no ventilation pipes down into the hold. I saved part of my clothes and sextant. The reason why I said you could not get a sailor to use a Davy lamp is because they are too careless. If there were two lamps, and one not a Davy lamp, they would take the first that came to hand.

(*By Mr. Darley.*) Even if their lives were dependent upon the use of a Davy lamp, and they were told so, it would be a question whether they would use it.

(*By Captain White.*) The hatches had been closed since Sunday forenoon to the time of the explosion.

(*By Mr. Darley.*) My captain was most certainly a sober captain, a very sober one. They opened and closed the sluice valves from the deck. The carpenter looks after them. As a rule I believe they open by a screw.

(*By Captain White.*) The main hold was full of coal, and in the after hold the lower part was full, and between decks there were bunker coals.

Thomas Booth.

Taken on oath before
Walter Wrangham.

William Vickery, of No. 45, Blackfriargate, Hull, Seaman (A.B.) I was boatswain on board the "Zeno." I have been to sea between 19 and 20 years. The "Zeno" was a screw steamer, brig rigged. She had 29 hands, all told. I joined her last November as able seaman. I was appointed boatswain late in December last. My duty was to forward the officers' orders in carrying on ship's duty in general. I had no night watch on the "Zeno." In the early part of May we were in Penarth Dock, Cardiff, taking in a cargo of coals. I believe they were steam coals. We took in, I believe, 2,000 tons, including bunker coals. We commenced loading on the Wednesday. We were bound for Port Said, I believe. The loading was completed late on Friday night or early on Saturday morning. I cannot say how the coals were put in. We had to shift the ship very often to let the spout come into different holds. I believe No. 2 hold was completely filled first, but I cannot say it was all filled at one teeming. I expect it was filled first, because it is most in the centre of the ship, and we can trim the other holds afterwards better. I think No. 3 hold was next filled, but I cannot say for certain. No. 2 hold was filled completely. No 3, to the best of my knowledge, was filled. No. 1 was partly full; in the after part of No. 1 there was not much space; the top of the coals slanted down, and at the hatchway I should think there was a space of 5 feet from the top of the coals to the combings. I should think close to the bulkhead there was a clear space of 12 feet, the entire depth of the hold being 16 feet. We hauled out of dock on Saturday at 5 p.m.; there was a dense fog. We drew up in the Penarth Roads. On Sunday morning we got out to sea. We sometimes went "dead slow." It was Monday noon before fog cleared. I know we stopped to take soundings once. I was present. After fog cleared off she was put on full speed. We were also under sail. The wind was easterly. The vessel was divided into compartments. I don't know that there was any ventilation to the cargo, except that leading to the bunker holes. There were iron ventilators formed to catch the wind, a kind of a cowl made to shift according to the wind. There were four altogether, for the purpose of ventilating the stoke-hole. The carpenter has charge of the sluice valves. I know of no other ventilation than that I have spoken of, excepting the hatches. After leaving the dock I believe the hatches of No. 2 were battened down. No. 1 was battened down at 6 on Sunday morning. No. 3 was battened down after leaving the dock. They were opened on Monday morning. It was no part of my duty to attend to these hatches. I have seen the book of rules provided by Messrs. Wilson. I have never read them. Without being a printed rule it is a general rule not to allow naked lights to be used in the hold.

(*By Mr. Darley*). On this particular occasion I knew of no verbal orders having been given to be cautious.

Examination continued.—All went well till Tuesday morning at 9, or little before. I was in the paint locker in the fore part of the ship, over the forepeak. On going there I heard Arthur Bennington, seaman, ask the lamp-trimmer, John Andean, for some waste. Andean is now on a voyage in the "Winestead" to Cronstadt. Andean answered it is in the forepeak. I afterwards saw Bennington with a lamp, a common spirit lamp, a naked lamp, in his hand going into the forepeak. That is such a lamp as is used generally in forecastles and engine-rooms for trimmers. Knowing the rule that a naked lamp should not be used, I did not remonstrate with Bennington for this reason, I knew he was not going into the cargo hold, and of course I thought there was no danger attached to it. I had not previously to this time smelled any escape of gas and had no notion that there was any gas about the vessel that was likely to explode. I saw Bennington at that time take up the trap-hatch; he got down himself and was standing on some gear that was on the first platform of the forepeak, only his head was above the man-hole then; he then took the lamp in his hand, and had to stoop. As soon as he brought the lamp over the hole I saw a flame and felt a shock. I was from 6 to 8 feet at that time from the man-hole. I was slightly burnt on the left side of the back of my head. I am now quite recovered. I never was taken to the hospital. Immediately after the explosion, when I was in the paint locker and lamp room, I felt myself partly buried; the fixtures in the forecastle were all blown in confusion. I tried to get on deck, but was a few minutes in doing so in consequence of the smoke and the things being thrown on me and the passage obstructed. I got on deck eventually. I thought that Bennington was still in the forepeak, and told Mr. Taylor, the chief officer. I saw Bennington shortly after on deck aft; he appeared to be much burnt. The master was on the bridge issuing orders. The chief mate was forward looking after things. We heard a noise, and chief mate said "Is that water rushing in." Orders were given, I believe from the captain, to take off the hatches from No. 2 hold; they were taken off; I assisted to take them off. I heard orders given, I expect from the captain, that we were to throw coals overboard, and some were thrown over. I went into the forehold with the chief mate and the carpenter. I found that the fore-bulkhead was blown into the forehold more from the port side; the greater part of it was blown down. Part of the plates were started from the port side; a midship stanchion supporting the foredeck was down. *I saw a* *quantity of rivet holes.* We attempted to fill the rivet holes up by putting in wooden plugs. We remained doing this until we were driven out by the water rising on us. I did not see any plates blown clean away. No. 1 hatch was covered by five iron hatches at the time of this explosion; they were battened down. The explosion blew the whole of them off the hatchway; I saw one of them on deck, but no more. The fore staysail and fore topsail were both set at that time, and both were torn; a derrick boom, five feet above the hatchway, was broken in two. The hatches had been covered with tarpaulin. I saw one of the tarpaulins lodged by the explosion on the fore topmast stay; that was from 30 to 40 feet from the deck. I saw the chief mate and some hands trying to lower a sail over the port bow. I did not assist. I imagine it was to try and stop the water rushing into the vessel. The captain was on deck attending to his duties all this time. There were no deck pumps going at that time; everything that I can judge of was taken to keep the vessel afloat when we found the ship, notwithstanding our exertions, was fast sinking. I heard an order passed to get to the boats. We all went to the boats; some to one boat some to another. After getting into the boats we were ultimately taken on board the "Brighton." The "Zeno" sunk 25 to 30 minutes after we left her; she sank in about an hour after the accident happened. We had general signal lamps, cargo lamps, glass lamps with vent holes at the top. Inloading at Cardiff, in trimming the ship, candles were used; the trimmers demanded them. The trimmers do not belong to the ship. No remonstrance was made to the trimmers using candles.

Taken upon oath before W. VICKERY.
WALTER WRANGHAM.

The Court here adjourned to the 12th June 1873.

12th June 1873.

WILLIAM VICKERY recalled.

Cross-examined by Mr. HEARFIELD.

I have been in several steam ships. I have no complaint to make against this vessel. I never was in a better found vessel. I have not the least complaint to make against the master. I have been before on board coal-laden vessels, with Welsh coals. In those cases it is the rule to keep the hatches open while in port. I have known ships go to sea with hatches off, and I have known cases where you could not proceed to sea with hatches off. The hatches were battened down the forehold on the Sunday morning, and continued so till the explosion. It frequently happens that vessels laden with Welsh coals must have their holds battened up a longer time owing to the weather. I am not aware that the weather has any particular effect upon Welsh coals in respect of their emitting gas. I am not aware that foggy weather makes any difference to them. This steamer had a half deck. The ventilators into the stoke hole passed though the half deck; they are large iron pipes, 3 feet in diameter, perhaps less. They might be 2 feet in diameter; they had bell mouths. I am not certain there was any means of ventilation from these pipes to the half deck. There is a slide in two of them in the between decks. There were also bunker holes besides these. In fine weather these holes are generally kept open. I believe some were open during the two days the vessel was at sea. I do not think the bulkhead could be made so tight as to prevent gas getting through; I think the working of the ship would make some outlet for the gas to escape through. I should think water would also drain through them; that is, a little hole might let through a great deal of gas and very little water. I went into the forehold after the accident. I observed the but straps; the rivets were out of them; the water was pouring through. When I got down below the water had got up to the top of the coals in the fore part. I went below about 10 minutes at most after the explosion. During that 10 minutes a large quantity of water had got into the vessel. I could not see the whole quantity of water coming into the vessel; I saw it pouring in at different places. From what I saw I should think she was damaged below principally. I saw some of the rivets clean out from the but straps. It would follow from that, that the plates must have been bulged out at the junctions. The forepeak and the No. 1 hold had iron decks formed of iron plates on angle iron formed in the usual way, therefore I should think that the decks would be of the same strength as the sides; at all events the deck would be very strong. I did not examine whether the aft bulkhead of No. 1 hold was damaged. Now, judging from what took place after the explosion, and considering the time we had to do it in, I think that everything was done that could be done to save the ship. I have the charge of the forepeak. I was last in the forepeak before the time of the explosion on the Monday forenoon. I had a light with me then. I did not observe then any particular smell of gas.

Re-examined by Mr. SAXELLYE.

The half deck had coals in it. The slides in the ventilators I have spoken of could be opened. I cannot say whether they were or were not open.

(*By Mr. Darley.*) The holes in the ventilators were closed with slides, about 2 feet broad and more than 2 feet in height.

(*By Captain White.*) I suppose I have been six or seven years in the coal trade. From leaving Cardiff to the morning of the 13th we had thick weather and a rolling but not a broken sea. The hatches were off No. 3 hold. I don't know of any reason why the hatches of No. 1 hold should not have been taken off from the Sunday morning at 6 o'clock to the time of the casualty. On the morning of the 13th at that time I should think the ship was going between eight and nine knots an hour. When we left Cardiff I should think that the freeboard of the ship was about 4 feet. The ship had not a great deal of sheer. I should call it a moderate sheer. I consider the cause of the explosion was a man going into the forepeak with a naked light. I cannot say that the rush of gas would be into the forepeak. The top-gallant forecastle deck was started. When the hatch was taken off the fore peak by Bennington I did not smell any gas. I should think that the reason the master ordered the hatches to be taken off the second hold was to let the gas escape out of that hold.

(*By Mr Darley.*) The master did not explain to me who he ordered the hatches of No. 2 hold to be taken off.

(*By Captain White.*) I did not at any time before the explosion during the voyage hear any orders given that the hatches were to be taken off. I should think that the reason they did not get the sail over the bows was because they could not get weights to sink it in so short a time. The rivet holes I saw open were in the but straps in the forehold. When the plugs were put in they filled the holes partially. I should think it was between 30 and 40 minutes from the time of the explosion before we left the ship.

(*By Mr. Wrangham.*) When we went to the boats, it was all hurry, but there was no confusion.

WILLIAM VICKERY.

The above deposition was taken upon oath before
WALTER WRANGHAM.

JAMES ALEXANDER KIDD. I live at No. 3, Fawcett's Terrace, Hessle Road, Hull, Marine Engineer. I was chief engineer on board the "Zeno" in the month of May last. I hold a first-class certificate for competency as marine engineer. The "Zeno" hailed from Hull. I joined the "Zeno" at London in July last. When we left Cardiff on Saturday afternoon, May 10th, we came to anchor, and banked fires. I know that all coals coming from that quarter are of a most gaseous character, but not to the extent there proved to be. We sailed on Sunday morning, and all went well until the Tuesday morning at 9. I had just left the breakfast table. I had got to my cabin, and felt a shock. My cabin is just over the engine, abaft. I listened for a moment, but hearing the regular beat of the engine, I came leisurely out, and saw some of the men running, who told me it was an explosion. I immediately went below to the second engineer in the engine-room to tell him the cause of the shock, and to tell him to stick to his post while I went and communicated with the captain. I went to the captain and spoke to him under the bridge, where he was issuing orders. The captain ordered all pumps to be put on. I mean the steam pumps. The captain had ordered at the moment of the catastrophe almost, by telegraph, that the engines should be eased. That was before I went on deck. When I returned from the captain, according to his orders I stopped the engines. I ordered the doors, smoke-box, and fire-doors to be opened, and blew off steam, and got all the men on deck. I was the last to leave the engine-room. I told the captain I would remain in the engine-room till he called me, and begged of him if he had to go not to leave me. There was no water coming into the engine-room before I left. We had sluice valves on board the ship. All the valves were closed. It is the rule to keep them closed. We never use them. I have another means of drawing the water off from the holds by means of pipes. The sluice valves were under the control of the carpenter. He would not open them without my orders. I am sure they are all water-tight. I have been seven voyages in that ship carrying wheat, and we never damaged a grain. I left the engine-room when it was determined to leave the ship. The captain, chief officer, and myself were the last to leave the ship. I had merely looked down into the hold. I saw the water coming in. The captain wished me to remain at the engines. I saw Bennington; he was much burnt. Three others were burnt. They were all well attended to. It is a general rule at sea no naked lights are to be used. I never saw the rules of Messrs. Wilson on board the "Zeno." Closed lamps and open lamps were used on board this ship. We had common spirit lamps. The use of a naked light on board a ship depends upon the kind of cargo we have. With some cargos, if a common seaman saw a naked light he would sing out himself. We left the ship 40 minutes after the accident. From the time of the occurrence to the ship going down was 50 minutes.

(*By Mr. Darley.*) We had hand pumps to every compartment, and all were shipped when they underwent survey by the Board of Trade. Two bilge pumps attached to the engine-room, communicating with every part of the room, worked by steam. We had a bilge injection we did not use. The engine-room was dry.

Re-examined by Mr. HEARFIELD.

I have no complaint to make against the ship or the master. I am sure he did everything to save the ship. From habit I have got somewhat accustomed to coals. I can pretty well tell their quality, but may still be deceived. I saw the coals put on board the "Zeno." I had no reason specially to believe that these coals were of an especially gaseous nature. I have before been on board a ship laden with coals at Penarth Dock, I think from the same drop. I have on such occasion laid in Penarth Roads when it has been blowing a gale of wind for more than three days with the hatches on. When we get to sea it is sometimes necessary to keep the hatches on for more than a week together. This ship was ventilated as vessels are usually ventilated, and better than a good many I have been in. When the ship first began to make water, if the sluice-valves had been open, I could have told by the manner in which my pumps threw the water out; the ship being down by the head the water ran down that way. Engine was 200-horse power registered. At the time the ship went down the engine was stopped. She was a strong and good ship.

(*By Mr. Wrangham.*) I have never known anything of the rules of Messrs. Wilson; there was not a copy in my cabin. The strictness as to lights depends upon what cargo we are carrying. With some cargoes common sense will tell a man not to use a naked light. The men themselves often call out, "No naked lights there." I am inclined to the opinion of the second mate that a Davy lamp would be of no use. If I had been captain of the ship I should have had the hatches down on the Sunday and Monday; the weather was such I should not have had the hatches off the forehold. I mean that as regards the cargo the ship was better ventilated than many ships I have been in. The hatch being off, No. 3 hold ventilated the whole of the after part of the ship. That was the only means of ventilating the hold where the cargo was; I mean by taking the hatch off. The forehold was not ventilated.

(*By Captain White.*) The ship drew on leaving Cardiff 15 ft. 16 in. forward and 18 ft. 8 in. aft. The ship had about 4 feet freeboard. If I had seen a man going into the forepeak with a naked light, as my business does not lay in that part of the ship, I hardly know what I should have done. If this accident had not happened and a man had been going down into the forepeak with a naked light I should not have thought that there was any danger, as so short a time had elapsed. The coal was dropped into the ship from a spout; the ship had to be shifted several times. I know they put in the coals very leisurely by driblets. The captain was at the ship when the coals were shipped; he was superintending generally. The Board of Trade survey was made of the "Zeno;" I cannot say when. It was in Hull, and since last July. At the time of the casualty we were averaging about eight knots. The coal I used for my fires was the same coal as the cargo. The coals were of good steaming quality. I did not observe it was gaseous; it was a hard, brittle Cardiff coal; it breaks all to pieces if hit by the hammer; it has the reputation of being of very gaseous quality. I have pipes connected with every part of the ship connected with my steam-pump. I did try to pump the water out of the forehold, but it did not draw freely on account of the head of the ship being down. The pumps were in excellent order; they did not pump as much water as I expected, owing, I expect, to the inclination of the ship. The rose of the pipe must have been covered. The pump was put on.

(*By Mr. Wrangham.*) The agent for the ship at Cardiff, Mr. Bovey, never gave me any caution relative to the coals, or stated that they were green coals. He never said a word to me about them.

J. A. KIDD.

The above deposition was taken upon oath before
WALTER WRANGHAM.

Police Court, 13th June 1873.

JAMES ALEXANDER KIDD recalled.

(*By Captain White.*) I had charge of the pump leading into the forehold from the engine-room. I had not seen the rose for a month or two; it would be two months prior to the accident. I am sure the pipe was clear, because I pump her out regularly every hatch. It is possible the pipe may have got damaged in the explosion. I should think it would be liable to be so. The rose was right down by the side of the kelson, right against the bulkhead. I was pumping from the forehold. I don't think the coals had choked it up. It would have taken two or three minutes to have lifted the sluice valve. The ship sank before the water could have run aft even if the sluice-valves had been lifted. The sluice-valves were about four inches square. It is impossible to save the ship by pumping.

J. A. KIDD.

Taken upon oath before
WALTER WRANGHAM.

GEORGE EDWARD COULTAS, of No. 4, Brigham Terrace, New Adelaide Street, Hull, ship's carpenter. I was carpenter on board the "Zeno." I joined her on the 9th day of October 1871, immediately after she was launched, and have been in her ever since. She was a first-class ship, and well found in every respect. We took in a cargo of coals at Cardiff in May last. No. 2 hold was filled up first, then No. 3 hold was partly filled, and then No. 4 hold was partly filled, then the forehold No. 1 was partly filled (she had no more put into No. 1). After that No. 3 was filled up as much as required, and then No. 4 was filled up, that completed her lading. We began on Wednesday and finished on Saturday morning. After we got under weigh and left the roads the hatches of No. 1 and No. 4 were off; that was on Sunday morning between 3 and 4 o'clock. No. 1 hatch was battened down between 7 and 8 on Sunday morning. No. 4 hatch was battened down just before dinner on Sunday morning. There was a nice breeze, and a bit of splash on. When all the hatches were battened down we had no ventilation in the holds. Nos. 2 and 3 hatches were battened down on the Saturday night after leaving the dock. I asked of the mate if there was anything more to go down, and he said "No." It was then my duty to batten them down, and I did so. No. 3 hatch remained battened down till 8 o'clock on Monday morning, the 12th of May. By the captain's direction I took two hatches off No. 3. It was done for the purpose of giving ventilation, and likewise of giving light to the trimmers. Those hatches remained off until the ship went down. On the Tuesday morning I received orders at 8 o'clock from the mate to take one or two hatches off all the other hatchways. After they had finished washing decks down the accident happened before I could carry out the order. I saw one of the trimmers go down one of the bunker holes on the poop deck on the Sunday night. He had a light with him. It was a common spirit lamp. I was never furnished with a copy of the rules furnished by Messrs. Wilson. I have seen them laid in the mate's berth. I have never read them or heard them read. The rules are not read on board the ship by the captain or chief officer. I am not aware of a rule that no naked lights are to be allowed in the hold for any purpose. I have been six or seven years to sea. I am not not aware of any rule on board ships as to the use of naked lights. I did not think it necessary to warn the trimmer when he went down the bunker hole. The bunker holes have lids, and are watertight. The men when they go below in the bunkers light their lamps between decks by striking a match. They generally leave their lamps below. They blow them out. On the Tuesday morning at 9 o'clock I was seated; I had finished my breakfast. I was seated in my berth in the forecastle. I saw Bennington come past. He was perfectly sober. He came on board at Cardiff in a boat after we got out of dock. Sometime after that he jumped overboard. When Andean told Bennington he could get some waste in the forepeak, Bennington asked Andean if he should require a lamp, and he told him he could either take a lamp or go without one, as he himself could get the waste without a lamp. Bennington took a lamp, a common spirit lamp. I was below, near the lamp locker then; when I got there he had got the trap hatch off, and was stood below. His head and shoulder were above, out of the hatchway. The hole is about 2 ft. by 18 in. The lamp was on the forecastle deck. He was drawing the lamp towards him when I got up to him, and when he got the lamp to the hole the explosion took place in the store room, which is part of the forepeak divided from it by a temporary platform. To get down into the forepeak we have bodily to lift up part of the flooring of the store room. The floor is all loose. I was about 3 feet from the edge of the man-hole at the time of the explosion. I was burnt on the right cheek and left arm. I was afterwards taken to the hospital at Liverpool, and remained there four days. At the time of the accident Bennington dropped down below. Shortly after I saw him on the deck; he appeared to be very much burnt. His clothes were partly singed. He could walk and was conscious, but not take care of himself. We had sluice valves on board the vessel. They were under my charge. They were all closed at the time. They were closed since we left Cardiff. As a rule they are always closed. After the accident I got out of the forecastle as soon as possible and went aft to the main deck. The captain gave orders to get the two quarter boats ready. I went aft and assisted at the port quarter boat. The captain came aft and ordered me to go forward and see what amount of damage was done. When I went forward the smoke the explosion had caused had cleared away. I went down into the forehold. I found that the forepeak bulkhead was blown down into the forehold. It was blown down about level with the box stringer. The box stringer is composed of several plates and bars of angle iron, about 18 inches broad, and it runs fore and aft the ship on both sides of the ship, and the one on each side of the ship is made fast to the side of the ship for the purpose of strengthening her. The forebeam was blown away from the port side, and the plates started from the stem. One of the large iron stanchions were blown down from the deck. I saw some rivet holes. Three of the straps from the buts of the plates were blown clean off. The rivets were blown out of some of the plates, and the plates were started on the stem. There had been five iron hatches on No. 1 hatchway; four of them had been entirely blown away. The remaining one was laid on the deck. I observed the topsail and forestaysail were split. The derrick boom was broken in two. The forecastle deck was started up two or three inches. One of the beams was bent up. I reported the injuries to the ship to the captain He ordered No. 2 to be unbattened, and the coals to be thrown out. Six or seven men went into the hold for that purpose. I went to the forehold and began to saw off wooden plugs, and the boatswain and the chief mate and another man or two who were in the forehold, began to fill up the rivet holes. We succeeded in filing up a good many of them. We remained there a quarter of an hour until the water drove us out. It was coming in pretty fast Coming up out of the forehold we saw some men bringing a sail to put over the bow. We got it over. It was not weighted. It had very little effect upon the vessel. I did not take the draft of the ship on leaving Penarth. I succeeded in saving part of my clothes. My berth was the first berth on the starboard side of the forecastle. Water was at that time in the forecastle up to the anchor lid. Shortly after the explosion I sounded the forehold and found 8 or 9 feet of water. I did not sound the main hold on account of not being able to get to the sounding pipe, as it was covered with coal. Before we went to the boats I and the chief mate made an attempt to put on the hatches of No. 2 hold, but did not succeed. We remained on board after the explosion took place 30 or 40 minutes, We were obliged to leave the vessel in consequence of her rapidly sinking. All the crew got in the boats, and independent of the injuries some of them had sustained, none of them were drowned. I saw the vessel go down. That was about an hour after the explosion. She went down head foremost in deep water. The crew was taken to Liverpool. We had the usual signal-lamps, cargo-lamps, and several spirit lamps. When they went into the hold, to the best of my knowledge, they used cargo lamps generally, either at sea or in port. In loading and unloading it is usual to use cargo lamps. Candles were used in loading with these coals. I do not know why. Labourers load the vessel. It was the case in this instance. No one remonstrated with them for using naked lights. I knew the coals taken on board were called steam coals. It was never intimated to me or in my presence that steam coals were dangerous coals. I have sailed in vessels with coals before, but not Welsh coals.

Cross-examined by Mr. Hearfield.

I have no fault to find either with the ship or captain.

George E. Coultas.

The above deposition was taken upon oath before

Walter Wrangham.

Police Court, 13th June 1873.

George E. Coultas recalled.

(*By Mr. Wrangham.*) The sounding pipe only came up to the between decks; the pipe did not come up to the upper deck. There were coals in the between decks and over the top of the sounding pipe which was covered with a brass cap. That was the reason I could not sound. It was only the sounding of the mainhold that I could not get at. I never heard that steam coal was dangerous. I had no information from the authorities of Cardiff about keeping the hatches off, and I never heard of the dangerous nature of this cargo. I know as a fact that the hatches were open all the time until we got out of the sea gate.

(*By Captain White.*) It was not in every case usual to carry coals over this sounding pipe. On taking in a previous cargo I have mentioned to the mate, Mr. Taylor, that I cound not get at the sounding pipes on account of the cargo being over them, but I did not do so on this occasion. As a carpenter, I do not think it to be a proper thing for a ship to proceed to sea with the sounding pipe covered. I saw the hatch put on No. 1 hatchway on Sunday morning, between 7 and 8 o'clock. To my knowledge it was not lifted from that time to the time of the explosion. There was no ventilation into No. 1 hold at all during that time. I suppose the mate's reason for ordering me to take the hatches off on Tuesday morning was for ventilation. No. 1 hold was partly filled forward; the top of the coals would be 12 feet from the deck, aft about 5 or 6 feet. No. 2 hold was full, No. 3 was full, and No. 4 was full. Over No. 3 between deck we had about 20 tons. We had no other open spaces that the coal could be put in. We could have carried 200 tons of coal more if they had been put in the sides of the ship in the between decks. And there would be about 30 tons of coals over the between decks of No. 4 hold. These coals were not placed in the forehold on account of the trim of the ship. I know all the pumps of the ship. There were two pumps in the forehold, one leading to the deck and the other to the engine room, they both drew from the after bulkhead. There were two more pumps in the main hold, one leading to the deck and the other to the engine-room; and there were two more in the after hold, one leading likewise to the deck and one to the engine-room. These leading to the engine-room were steam pumps. We had not a portable pump in the ship. When we were driven out of the hold by the water there would be about 10 or 11 feet of water in the hold. If the pump in connexion with the engine-room was on it ought to have thrown water. If it was on I cannot account for its not throwing water. The hand pump was never put on to the forehold. I suppose there was not sufficient time to do so, every man being otherwise employed to the best advantage. It was my duty to rig the pump, and I was othewise engaged. I did not rig it because I was ordered to do something else. It would have taken me three or four minutes to have rigged it. I saw the rivets drawn out of the side. I suppose that was done by the force of the shock. If the rivets were good they would draw and not break off. The mate ordered me to put the hatches on the No. 2 hold. I suppose he thought there was a chance she might not not go down, and it was to prevent any water that come on the deck getting into the hold; if she did not sink we might have got a ton. I don't think if the sluice valves had been opened and the water in the forehold allowed to run off into the engine-room, and the pumps put on, that it would have done any good, she was making too much water. The first boat, the jolly boat, was out in three minutes. We got the long boat, the cutter, out; we did not get the life boat out. I was not present all the time when they got the cutter out. I remained there about three minutes. There were three or four men assisting me.

(*By Mr. Darley.*) It was my duty to examine the roses of the pumps leading to the engine-room, and the deck pumps. I did not examine them on this occasion previous to going to sea. They are protected from coal underneath the limber boards. I had examined the roses about 10 or 11 days before going on this voyage. I found them then in good condition. There was no accumulation there likely to choke them. I saw some of the rivets that come out. They were on the box stringer. They were drawn, and I infer they were good rivets. I consider it a proof of good work. The but straps were bent, not broken. None of them split across that I noticed.

(*By Mr. Wrangham.*) There would have only been three or four tons of coal to be shifted to enable me to sound down the sounding pipe of the main hold. I cannot tell how long it would have taken them to have shifted them. There was no other means of sounding. I could not have sounded down the pumps.

George E. Coultas.

The above deposition was taken upon oath before

Walter Wrangham.

Arthur William Bennington, of No. 34, Sutton Street, parish of Holy Trinity, in the borough of Kingston-upon-Hull, able seaman. I was an A.B. seaman on board the "Zeno." I joined between the 12th and 15th of last September. The vessel was at Cardiff in May last. I was paid off on the 8th May. I signed again on the 9th, and joined her again on the 10th, at Cardiff. I went off in a small boat to her in the evening. We got under weigh on Sunday morning between 3.30 and 4. I was not sober when I got on board. I jumped overboard. I suppose I wanted to get ashore. I got in again from the pilot boat. The vessel started in her voyage at 4 a.m.; it was foggy; she went slow. On Tuesday morning, the 13th of May last, I came on deck at 8 o'clock. I relieved the second mate's watch. After washing saloon deck I was ordered by the third mate to clean some brass work. I went into the forecastle to ask the lamp trimmer for his keys of the lamp-room to get some waste and oil to clean the brass with. There was no waste in the lamp-room. I told lamp trimmer. He said there is a bag full down in the forepeak. I went to the peak, took the hatch up, looked down, and saw it was all dark. I went into the lamp-room, and found a spirit lamp burning in the lamp-room. I took the lamp out of the lamp-room, and set it down on the deck whilst I got down the man-hole into the peak used as a storeroom. I was stood in the hole. The The carpenter and boatswain asked me what I was doing down there. I told them I was going to get some waste. It was a naked lamp. They never said a word to me at all about the lamp. I took the lamp, and as soon as ever I got it over the man-hole there was an explosion. When I came to my senses I found myself at the bottom of the peak, some 15 or 18 feet deep. The temporary deck on the storeroom was all blown away and laid about me. When I came to myself I found myself badly burnt on both arms and on the legs just above the boot tops, and all my hair but one tuft was burnt off. My face was burnt. My moustache and whiskers were burnt off. My clothes were a mass of ashes. My jacket fell to pieces. I had no trouble to pull it off. I must have remained insensible a few minutes. I got on my feet, and fell to the side of the ship. I managed to climb up to the upper part of the box stringer of the peak; then I felt my way aft to the starboard side of the bulkhead. I found the man-hole blocked up. I sung out for help, but could not make any one hear. I sat down on some of the gear, and by and by the smoke began to go away, and then I saw a light. I then went along the box stringer, and made for this light. I found the rivets blown out, and I got some fresh air by putting my mouth to them, which revived me. The water was also coming in fast. I went back again on the starboard side to see if I could get through the man-hole again. I could not, and I went into the wing of the bulkhead on the starboard side, and at last I found a plate of the bulkhead blown into the forehold on the port side. I got through and went on the box stringer as far as the hatchway, and then I got on the coals. The hatches were all off. There was plenty of light. I got out by the hatchway by myself. The coals were high enough for me to get hold of the combings, and I got out. My injuries were at once attended to. The steward dressed my wounds. I saw nothing more of the damage done to the ship. I had never tasted drink since Saturday. The lamps I used were those used generally in a forecastle. There were cargo lamps on board. We had signal lamps. Side lights. I don't think we had any lanterns. I have loaded twice at Penarth and twice at Cardiff with coals. I have had no orders given to me about the explosive character of coals by agent or anyone else. Last cargo of coals we never had a hatch off. We went to St. Nazaire. We were about five days on the voyage. I had no reason to suppose in going down to the hold with the lamp there would be any danger. I never smelt anything. The accident took place between 8.30 and 9 a.m. I did not see the "Zeno" go down. I was taken to Liverpool in the "Brighton," and then sent to the hospital in Liverpool on the 16th of May. I was discharged from the hospital a week last Wednesday. I remained an out-patient for a day or two, and then I came down to attend this inquiry.

Cross-examined by Mr. J. W. Hearfield.

In the last ship I went down into the forepeak with a light. I never went down into the hold of a ship carrying coals with a naked light; I never had occasion. The hatch would be off the man-hole about three minutes before I got a light. The man-hole was round; it would be about 18 inches in diameter. A man could easily get down it. After I took the hatch off I went to the lamp-room; the lamp I took was constantly used for going down there. The carpenter was down in the same place with this lamp on the Sunday afternoon. I suppose nobody would think there would be danger to go down into the forepeak with a naked light in that short time. No one but the carpenter and boatswain saw me go down. I never gave a thought about the gas. I did not know that gas coming from coals does not smell at all. All the rivets on both sides of the peak appeared blown out from the stem aft. I could see the water teeming in wholesale through the rivet holes.

(*By Mr. Wrangham.*) The forehatch was battened down between 6 and 8 a.m. on Sunday, and the carpenter went into the forepeak in the afternoon.

(*By Mr. Darley.*) I think the rivets were blown out for 6 or 7 feet, up and down on both sides. The but ends were all started; the buts were separated from the stem an inch or three-quarters of an inch. I did not notice whether it was more so on one side than on the other.

Arthur William Bennington.

Taken upon oath before
Walter Wrangham.

John Bovey. I reside at Penarth, and am a shipping agent. I remember the "Zeno" loading at Cardiff; she completed her loading on the morning of the 10th of May last. She was in the Penarth Dock. I attended as the agent of the owners of the ship. The cargo was taken in their vessel on freight. I am Lloyd's agent at Cardiff, and I have issued a policy for my principals for 2,000*l.* on the cargo in this ship. During the time she was loading I was at the ship, on Friday the 9th of May. I was in conversation with the chief mate and engineer. To the chief engineer my conversation was as to the readiness of the ship. The conversation I had with chief mate was on the spout alongside the ship. It was as follows: I called his attention to the necessity for ventilating the cargo by keeping the hatches off. He was to keep them off from that time to as long as practicable. I stated to him my reason for wishing it to be done. I told him that the coal that was being put into the "Zeno" was fresh wrought (that is fresh from the pits), and pointing to some coal in waggons alongside, I remarked, "Now that coal you see there is very recently from the mine, and will generate gas." I stated that in order to support or strengthen the reason for keeping the hatches off. I know the rules of the Penarth Dock. I refer to Rule No. 18; I have read it. I know why that rule is made. It was made because the parties who made it knew that the coal that would be put in ships at Cardiff would generate gas, and that, unless well ventilated, there was the risk of explosion, which happened in the case of the "Zeno." This rule is framed in the protection of local interests so as to prevent an explosion in the dock. I have been about 16 years connected with coal, and know well the character of Welsh coals. I have known an explosion take place in a ship whilst loading with Welsh coals. The accumulation would only take place where there was no ventilation. I should think there would be great risk of an explosion in a ship that had received coals into her in the morning if a light was used in the evening, if there had been no ventilation. Strangely the gas generated by Welsh coals is inodorous. Fresh-wrought coal will give off more gas than coal that has been exposed if both were stowed away. The engineer did not hear this conversation. It is usual at Cardiff for the trimmers to trim the coals in a ship with candles; they would refuse to use a lantern. Candles are not dangerous, because there is good deck ventilation. They only use candles because they give a better light than lamps. The gas from Welsh coals is rather light than heavy. At the time of my conversation with the mate I explained to him the different modes of ventilating cargoes; that I had not any faith in any other mode than deck ventilation, that is by taking the hatches off and leaving them open. The coals from every colliery in Wales will generate gas, but not one more than another. It is notorious with us that explosions from the gas of the coal are more frequent in foggy weather owing to the depression. When I went first on board the "Zeno" I inquired for the captain. The mate said he was on board, and wished to call him for me to see him. I said it was unnecessary to do so. Considering the mate as being the executive, and in charge of the vessel, superintending the coal being put on board, and in shifting the ship, I could have then seen the captain if I had wished. I never saw the master to have any conversation with him on the subject of the coals being dangerous, or of the same tenor as that I had with the mate. The "Zeno" had exceptional despatch in loading; she was loaded in 50 hours with 1,500 tons, and that would tend very materially to cause an accumulation of gas.

Cross-examined by Mr. J. W. Hearfield.

One of the reasons for my going to the ship was to caution him about the coals. I should have an interest in seeing the ship loaded with despatch. Loading 1,500 tons in 50 hours would be a great despatch with us. I had given the freighters twice as much time to load in. The sailors would see the trimmers carrying naked lights, and it would very likely put them off their guard. I had no conversation on the subject with anyone but the mate.

There is no fear of an explosion without a light. The gas does not affect the sense of smell, or the lungs in breathing. I have no recollection of telling the mate that it was usual for the shippers of coal to give notice that the coal was dangerous. There are no painted notices, or notices of any kind posted about on the dock sides giving notice of the dangerous qualities of the coals. I think it would be very advisable if it were so. I had conversation with the shippers as to their not sending the usual notice that masters of vessels are particularly requested to keep the hatches off to avoid any explosion from the gas emitted by the coals. One of the firm stated that to me. They were not in the habit of giving such notice. The firm was Cory Brothers & Co. What he meant to say was they never printed any notices.

Cross-examined by the mate, Joseph Whalley Taylor.

We had the conversation I spoke about 9.30 p.m. We were on the staith. I had about half-an-hour before that seen you on the deck of the vessel. I do not remember you asking me why I would not go down to see the captain. It is very possible. I should explain to you that I was desirous the ship should be loaded as soon as possible, as I wished to carry out the wishes of Messrs. Wilson. We were in conversation the first time on the deck about five minutes. I possibly did ask you if the ship would get off on the morning's tide, and you said, "Yes, as far as the loading was concerned, but the boilermaker had not done with the boilers." I then inquired for the chief engineer, and you directed me to his berth. I was in conversation with the engineer as you left me. I may have been with him 10 minutes, and then I went on shore, and up to the drop head. You came up at my request. After speaking to you, and cautioning you about the coals, which was the purpose for which I wished to to see you, we had a general conversation. It may be that you came up to me for other purposes than what I wanted you for. I always found you attentive to your duties.

(*By Mr. White.*) I do not consider in reality that there is any danger in loading a ship so quickly as the "Zeno" was loaded.

(*By Mr. Darley.*) Our coal is not liable to spontaneous combustion. The coals from Swansea are liable to spontaneous combustion. I had an interview with the captain every day. He used to come up to my office. I always found the captain attentive to his duties. I have the highest respect for him.

John Bovey.

Taken on oath before
Walter Wrangham.

Police Court, Borough of Kingston-upon-Hull,
8th July 1873.

Before Walter Wrangham Esq., Police Magistrate.
Captain White, R.N.
William Darley, Esq., Naval Architect.

Mr. Saxellye for Board of Trade.
Mr. John Hearfield for Captain Owen (Master).

The mate, Joseph Whalley Taylor, appeared in person.

(Master's certificate handed in again.)

Adolphe Pièrre Vassard, of No. 25, Finsbury Place, City, member of the "Polytechnic Society of Paris" and also of the "Chemical Society of Paris," consulting chemist and professor of chemistry in London. I have for five years studied the qualities and descriptions of English coal. I have been in England four years. I now hand into the Court my opinion as to the explosive qualities of coals. I have been requested by the Board of Trade to examine into the quality of coals, and particularly the Welsh coals. I have read the evidence which has been taken on this inquiry which has been furnished to me by the solicitor of the Board of Trade. I there find the explosion took place in consequence of the emission of an explosive gas. I have come to the following conclusions (see exhibit marked "V." annexed). I mean by sulphate of alumina in its crude state, ordinary clay treated by sulphuric acid. The Cardiff coal—hard, brittle coal—contains light carburetted hydrogen. That was the coal on board the "Zeno." The Cardiff coal gives off at 61° Fah. $\frac{3}{5}$ of a cubic foot of carburetted hydrogen gas per ton in half an hour. Cardiff coal exposed to a temperature of 100° Fah. gives off per ton in 36 hours 4 cubic feet and 138 cubic inches of carburetted hydrogen gas after giving off 2 cubic feet of same gas at the ordinary temperature in 12 hours. This gas is inodorous, and at once ignites on the application of a light. A person going into a forepeak where this gas was would not smell it, and it would not affect his breathing—it is not poisonous. He could not, without a light, tell its presence. To prevent explosions of this sort I should adopt a system of ventilation by shafts. I would recommend that coal should be exposed for more than eight days before it is shipped. It would then be not quite so liable to generate so much gas. According to the liabilty of the coals to emit gas they ought to be exposed for several days. The coal ought to be examined before it is put on board to know what quantity of gas it gives off. This could be done by a properly arranged cylinder; the amount of gas in a given quantity of coal could be thus ascertained and the captan of the ship informed how long he could with safety keep the hatches shut. I have long studied the explosive character of coals. I have recommended ventilation as a means of preventing explosions. Coals are a little injured by being exposed to fog. The fog would moisten the coal and render it liable to heat. The fog has no effect upon the coal to generate gas. The reason why more explosions occur in coal mines during foggy weather is because the ventilation is not so good. The effect of fog on coal has a tendency to cause spontaneous combustion and that only after lengthened exposure, and that on small coal. I have examined the drawing produced by Mr. Darley showing how vessels may be ventilated in various ways, and I certainly approve of that mode of ventilation. If this mode of ventilation could be applied to all vessels it would prevent explosions and would be effectual in allowing the gases to escape. The ventilator shown in the drawing carrying air to the bottom of the vessel is of great importance inasmuch as the carburetted hydrogen being lighter than the air, the air admitted into the hold would force the gas upwards. If one of those ventilators had been introduced into the forepeak of the "Zeno" I do not think the accident would have taken place. The plan produced is complete for the purposes intended.

Cross-examined by Mr. Hearfield.

The emission of the gas in Cardiff coals is caused by the breaking up of the larger fragments, and therefore opening the little cells in which the gas is contained. Each cell contains gas. It is the friction or leakage which liberates the gas, and burning also liberates the gas; that gas can be smelled. The gas contained in the Cardiff coal is carburetted hydrogen, or by a simpler name, "marsh gas," and is the same as "fire damp" in mines. Coals newly taken from a pit will emit a very large quantity of gas. About eight days ought to elapse before Cardiff coals should be put on board ship after being taken from the mine. If shipped earlier I should call them green coals. A captain of a ship would not know what were green coals; he ought to have been informed of this, especially as to Cardiff coals. If these coals had been kept eight days they might have been shipped and the hatches kept down for 30 hours with safety. The captain ought to have known more than the mere fact that they were Welsh coals; he ought to have been told they were green Welsh coals. In my opinion it is not proper to ship Cardiff hard, brittle coal at any time, after any amount of exposure. It would not be safe to ship them at all. I think the effect on these coals was caused by the action of the ship. Any kind of coal is liable to break by the motion of the ship. If there was no motion of the ship there would still be an emission of gas. The ordinary motion of a vessel at sea will pulverise coal. If these coals had been in perfect condition when shipped, I should not have advised the captain to take off the hatches during a fog. In case the coals were shipped in good condition on the Saturday, and the hatches were closed on the vessel's sailing on the Sunday, and a fog came on and continued during Monday, and the hatches were opened on the Tuesday morning, I should say they were opened as soon as they ought to have been. I never heard of a dry fog. There is always fog in the atmosphere, but you cannot see it. As soon as you see it we call it fog. If the hatches were left off the fog would saturate the coal; it would affect the coal worse than rain. It would not be proper for the captain of a ship to keep open his hatches during rainy weather; during foggy weather to do so would be much more improper. In my opinion it all comes to this, that these coals were shipped in an improper condition—too green from the colliery. Independent of experiment or notice given, the captain or owner would have no means of knowing the dangerous nature of the coals. If the light had been encased no explosion would have taken place. If the lamp had been supplied with air from the bottom of the lamp an explosion would have taken place. Practically there would be no difference between an ordinary ship lamp (encased) and a naked light. It would require a Davy's lamp to prevent an explosion, just as much as in a coal mine, if proper ventilation was not given. Even if vessels were properly ventilated as shown by Mr. Darley, I should never advise coals to be shipped until they had been several days from the pit.

(*By Mr. Wrangham.*) If a ship is loading the breakage is very great, and if a man were to go into the bunker with a naked light, even if the hatches were off, an explosion might take place, as the gases would be then escaping very freely. A ship supplied with Cardiff hard, brittle coal should use only "Davy" lamps.

(*By Captain White.*) I have never heard of coal being washed before it has been shipped. If the coal is wet when shipped, it will give out gas just as soon as if it was dry. The effect of wet on the coals is to produce spontaneous combustion, but this very rarely happens when the coal is in large lumps. I consider the hard, brittle coal of Cardiff to be more dangerous than other coals, owing to its explosive character. The effect of fog on the coals would not render them more explosive. I should consider it more prudent to keep the hatches off than to close them down. The Cardiff coals are not liable to spontaneous combustion. I consider it would be much safer if the cargo was divided amidships fore and aft the ship by planks placed Venetian-wise, so as to admit of the gases passing out. The space should be 15 or 18 inches wide. I also consider that a draught might be made by letting the pipes from the hold be led to the galley fire. These gases are all light gases. There is only one explosive gas, carburetted hydrogen. It is half as light as air. If the ship was fitted with these ventilating planks, all the gases would rise to the surface. If each hatchway was fitted with a pipe one foot in diameter that would be sufficient to allow the gases to escape. This explosive gas of carburetted hydrogen will explode at a heat of 123° or 124° Fah. There are no means of telling when this gas is present, except by applying a light. The coal upon which I made the experiments I do not know how long it had been brought from the mine. It would be better not to ship Cardiff coal at all, but if shipped, I recommend proper ventilation on board.

(*By Mr. Darley.*) I think the loss of the "Zeno" was not from spontaneous combustion, but by the application of the flame to the gas. The humidity of the atmosphere would not have a tendency to soften the coal. If the coals were small and wet at the top it would make very little difference in the rising of the gas. I am of opinion that the gas that found its way into the forepeak was generated in the forehold, making the forepeak into a receptacle for it. The deck and bows being both air-tight and water-tight, and the bulkhead not being air-tight the tendency of the gas to be pressed into the forepeak from the body of the coals, there being no agent to drive it back again, would cause the air to gather in the forepeak. I think the captain acted with great discretion towards the cargo by keeping the hatches on during a dense fog. My opinion is that any kind of ventilation that carries off the gas must be good. We must endeavour to find the best mode. I think that the Board of Trade should make it imperative that a good system of ventilation should be enforced in ships carrying coal. I think the coal owners should be compelled to give written notice to the captains and officers of ships as to the peculiar properties of the coals they ship, and the quantity of gas they are likely to give off in a given time, and the length of time the coals have been wrought from the pit. I think iron perforated tubes laid amongst the coals would be injurious as the water might come in contact with the iron, and produce hydrogen by its electric affinity, which is highly explosive. If a cowl had been supplied to the forepeak, and the fog had come in, the fog being heavy would have descended to the bottom, and driven the gas out, provided there was an escape for it.

A. Vassard.

Taken upon oath before
Walter Wrangham.

Official Report of the Inquiry.

The "Zeno" was a screw steamer, built of iron, and was of the following dimensions, viz.: length, 272 feet; breadth, 32 feet; depth, 16 and 18 broken; gross tonnage, 1,490 tons; horse power, 200, with two surface-condensing combined inverted engines; draught of water forward, 15·7; ditto aft, 18·7; freeboard, 4 feet. She was the property of Messrs. Wilson, Sons, and Co., of Hull. Her estimated value was 33,000*l.* She was insured for 11,000*l.* She was built in 1871 by Messrs. Earle and Co.'s Shipbuilding Company, Hull, and classed 18 years Liverpool. She was brig-rigged, and manned with 29 hands all told. Was commanded by Captain Edward Owen, who holds a certificate of competency. She was divided into four compartments for hold, and the bulkheads, with one exception, were of iron and watertight, and fitted with suitable sluice valves, and arrangements for pumping from each compartment. The ship was well found in every respect. She commenced loading on Wednesday, the 7th of May, in the dock at Cardiff, the cargo taken in being 1,500 tons fresh wrought Cardiff hard brittle coal from the pits, all being loaded in 50 hours. The shippers were Messrs. Cory Brothers and Co. Her loading was completed about 1 o'clock on Saturday morning, the 10th May. She left the dock the same day (Saturday) at 5 p.m., weather foggy. The hatches were closed as follows: No. 2 on Saturday night, Nos. 1 and 4 on Sunday, and No. 3 on Monday. They were not battened down till out at sea. There were fires used in the forecastle, and lights as usual. On Sunday afternoon the carpenter went into the fore peak with a naked light (the same lamp subsequently used when the explosion took place). On Monday forenoon, the day before the accident, the boatswain went into the forepeak with a naked light. In consequence of the dense fog that prevailed the "Zeno" lay in the Penarth Roads until Sunday morning, the 11th May, between 3 and 4 o'clock, when she got underweigh, and proceeded slowly, the fog continuing until the afternoon of Monday, when it cleared away. On the same evening (Monday) the captain gave orders that the hatches should be removed for ventilation on the following morning, which was partly carried out. All went well until the following morning (Tuesday) about 9 o'clock, in lat. 46° 45′ N., and long. 8° 11′ W., when one of the seamen, Arthur Bennington, requiring some waste, was directed by John Andean, the lamp trimmer, to the fore peak for some. Bennington took a common spirit lamp (a naked light), and removed the wooden hatch leading to the fore peak. He placed the lamp on the deck, close to the hole, and got down, standing on some gear, in which position as he stood his head was above the deck. He had to stoop to get below the deck, and, taking the lamp in his hand, as soon as he got it below the deck, an explosion took place, bursting the platform below him and precipitating Bennington into the lower part of the bow, a distance of 14 or 15 feet. He was much burnt, and rendered for some short time insensible. The fore water-tight bulkhead which divided the forehold from the forepeak was blown into the forehold, the deck above disturbed three or four inches, and the pillar to beam carried away. The butts of the plates of the bottom were separated from the stem on each side for a distance of 6 or 7 feet below the water, being open about 1¼ inch. Some of the butt straps were ripped from the port bow, and the plate started, and a great many rivets drawn out. The explosion found vent through the fore hatchway, blowing up five iron hatches in its passage, which in their flight broke the derrick boom into two pieces, and shivered the mast, also tearing the foretopsail and forestaysail. The casualty arose from gas being generated in the lower part of the coal in the forehold, which found its way through some small aperture in the fore bulkhead into the fore peak, where a natural receptacle was formed for it, the greater part of which must have accumulated in much less than 24 hours, and the explosion of which was due to the dangerous use of the naked light used by Bennington. Captain Owen was on the bridge at the time of the accident, and immediately ordered the removal of the remainder of the hatches. A sail was got over to endeavour to cover the aperture in the port bow, but failed for want of weights. Plugs were made and driven into the rivet holes, until the men were driven out by the water gaining on them. The captain, seeing danger, ordered three boats to be swung out at the davits to within four feet of the water. A signal of distress was hoisted, which was answered by the "Cairo" and "Brighton." Finding the openings on the sides of the stem and on the port bow were so large, it was thought advisable to keep the sluice valves closed, and the steam pumps being used without effect, steam was blown off. On all hopes of saving the vessel being abandoned, the whole took to the boats about 40 minutes from the time of the accident (the captain being the last to leave), and were picked up by the "Cairo," outward-bound, afterwards transferred to the "Brighton," the weather at the time being fine and clear. From the time of the accident to the "Zeno" going down head foremost in deep water in the Bay of Biscay was about 50 minutes. The Court, upon weighing the whole of the evidence produced, and aided by the scientific information from Mons. Vassard, have come to the following judgment: that no blame whatever attached itself to the owners, Messrs. Wilson, Sons, and

Company. From the very high reputation of Messrs. Earle's Shipbuilding Company they have the utmost confidence in the substantial construction of the "Zeno" and of her general efficiency. They exonerate Edward Owen, the master, and return him his certificate, the usual notice on shipment of dangerous Cardiff coal not having been given to him. With regard to Joseph Whalley Taylor, the chief mate, they consider he neglected his duty in not informing the captain of the dangerous condition of the coal after having been informed thereof by the agent at Cardiff. His certificate is therefore suspended for three months from the 11th of June. The Court feel bound, however, to point out to the Board of Trade the very dangerous properties of the Cardiff steam hard brittle coal, such as shipped in the "Zeno," as shown by the scientific evidence of M. Vassard, with the view of stringent instructions being given to prevent vessels going to sea without some efficient ventilation. Various means were suggested, amongst which were the following: a comprehensive system of ventilation from the upper deck by pipes, cowls, &c., as described in drawing accompanying, observing that had the "Zeno" been fitted with a cowl and ventilating pipe to the forepeak, this accident would not have occurred. The use of iron masts, uptakes to funnels of steamers, bilts, &c. By dividing the coal fore and aft by planks placed Venetian way, with a space between them, against the pillars of the hold. Also the funnel of the galley fire being utilised by means of pipes leading to it from the various parts of the hold. That each hatchway be arranged so as to admit of cowls being fitted to allow of ventilation when the weather prevents the hatches being taken off. It may be remarked here from evidence that it is more important with Cardiff hard brittle coal to have ventilation than to keep out water.

Walter Wrangham,
Stipendiary Magistrate.

Police Court, Hull, July 9, 1873.

We approve of this report,
E. A. White,
Captain, R.N.
Wm. Darley,
Naval Architect.

THE "BERWICK."

Greenwich Police Court, 26th September 1873.

Inquiry into the circumstances attending the casualty on board the screw steamship "Berwick," on the 9th of May 1873, while on a voyage from Shields to London; made by direction of the Board of Trade by Daniel Maude, Esquire, stipendiary magistrate, assisted by Admiral Powell and Mr. Darley, acting as Assessors.

Minutes of Evidence.

Charles Almond sworn.

I was first mate on board the steamer "Berwick" in the month of May last. She was loaded with coal in the port of Shields on the 8th of that month. She took in 732 tons gas coal. We had carried that description of coal before, a great many times, to various ports on the Continent. She left Shields on the 8th of May, bound for London; on the following morning we passed the Dudgeon light at 4 o'clock, and at 5 a thick fog set in, and the engines were eased half speed in consequence. I was on deck at the time, and at 6 o'clock there was an explosion in the fore end of the ship. I was on the bridge. I saw a quantity of smoke, wreck, and dirt fly into the air, and a man I saw fall on the deck on his head; that man was John Morrison, one of the firemen. I did not leave the bridge, there being a thick fog on. I stopped the engines. The man was shot up into the air about 14 feet. I saw no flame with the explosion. The captain and one of the men went forward to Morrison. I had not noticed Morrison before the explosion; I conclude he was below in the forecastle. I saw some men, two, come up from the forecastle after the explosion, hurt. When we came to London an inquest was held on Morrison. I cannot account for the explosion; we never had one before on board. The ballast tank was empty at the time, the water having been taken out before shipping the cargo. There is a store room, about 9 feet wide, between that tank and the cargo; that room was empty also, with the exception of a few stores. There are two hatchways in the store room. There were two holes in the tank for ventilation, which came into the forecastle; one hole was to sound the tank with, and the other hole was to allow any water that might get on to the top of the tank to run into it. There is a pipe from the tank to the engine-room. I don't know how far the pipe runs. I don't know that it ran as far as No. 3 compartment. There was a cock on that pipe. I don't know whether that cock was open or shut at the time of the explosion; it was under the care of the engineer; he would be the person to look after it. I did not leave the bridge till 8 o'clock. When she arrived in London on the following day, I went into the forecastle and examined the damage, and found that the tank top had been lifted, and some of the beams of the tank were broken; that was on the port side. The pipe that I have been speaking of was amidships. There was a little damage done to the deck on the starboard side. That was all I saw. There was a wooden deck above the tank; that was injured also. That wooden deck was a lining over the iron deck. The two men that were injured were also firemen. They were in hospital, one a week, and the other a little longer.

(*By Mr. Crossman*, who appeared as solicitor for the master and owners.) I have been three years in this steamer on the 9th of last June, and always engaged in carrying a similar class of coal. We make from 45 to 50 voyages a year; and this was the first explosion. There is a fleet of steamers employed in the same trade. Morrison and one of the men that was injured were off duty at the time of the explosion; the third man had just gone down into the forecastle to call them out of their beds. The cargo was stowed the same as usual, and we had fine weather. The hatches had not been put on. The forecastle is a very large one. The top of the companion of the forecastle had not been put on, and the doors were not shut. There is an iron bulkhead between the store room and the forecastle, which runs down to the bottom of the ship, and that iron bulkhead cuts off the tank from the store room. The store room is 9 feet in width, and extends from the deck to the floor of the ship; then there is a wooden bulkhead which cuts off the storeroom from the forehold. The pipe from the tank that I have been speaking of runs under the ceiling of the forehold and under the store room.

(*By Admiral Powell.*) We have two tanks; one is in the middle of the ship, in that we put cargo, and that tank at the time of the explosion was full of cargo. I have no reason to believe that the empty tank was leaky. All the holds had the hatches off, in order to let the gases off. It was the duty of the second mate to see to the stowage of the cargo. We have Davy's safety lamps for the store room, but in the forecastle there is an ordinary lamp and a fire. There was no indication of an explosion in the store room. There was an iron lid to the empty water tank which was screwed on.

(*By Mr. Darley.*) There was only one man-hole in the top of the empty tank, and that was fastened on. It was a square man-hole, and the lid was of iron, secured by screw bolts, and india-rubber packing round the lid. There was a wooden top on the top of that again, so as to make the deck flush. There was no access to the tank by any other means. The cock for emptying the tank was close to the bottom of the ship; it was shut off or opened from the store room by a lever. I suppose that the explosion took place in that tank. I have no reason to believe that the bulkhead was not air-tight. The hatches were off at the time of the explosion. The forecastle is on the top of the tank. The sounding pipe of the tank was not shut. That pipe came out under the forecastle hatch.

(*By Mr. Maude.*) There was a hole in the top of the tank to allow water that might be shipped to run into the tank.

(*By Admiral Powell.*) We had no paraffin or combustible matter in the forecastle. I did not see myself the hole on the top of the iron tank. I was only only informed there was one.

(*By Mr. Darley.*) The second engineer generally took the soundings in the tank. The wooden bulkhead I don't believe was water-tight; that runs right down to the ceiling of the ship. It is a wooden ceiling. I don't know how that ceiling was fastened to the floor of the ship. There was nothing shifting but the limber boards; the limber boards were only on one side, the starboard side, close to the kelson. By lifting the limber board you could get under the ceiling. There are some ventilating pipes in the fore hold; they were not filled at the time of the explosion. We have Davy's lamps in general use if we want to go below.

C. Almond.

The within deposition of the said Charles Almond was taken upon oath before me at the police court aforesaid this 26th day of September 1873.

D. Maude,
Stipendiary Magistrate.

JOHN BAXTER sworn.

I reside at the Tyne Dock, and am a coal trimmer. I was employed to trim a cargo of coals in the "Berwick" on the 8th of May last; they were gas coals, about 700 tons, all gas coal. We warn all strange vessels as to the danger of these coals. We are cautious about all gas coals—about using a light in the hold of a ship. We use a naked light in loading a ship. The second mate had charge of the ship; he had nothing to do with trimming the ship. I was trimming for the owners of the ship. The second mate said she was to be full.

(*By Mr. Crossman.*) We warn foreign ships. The North-eastern Company have had boards posted for the captains of ships not to cover up the hatches when partly filled till she has got in all her cargo. That caution has only reference to gas coal cargoes; that caution is not given to regular traders, because the coals in those ships do not remain sufficiently long, and because they know the nature of the coals. The caution is not given to the masters of the vessels.

(*By Admiral Powell.*) I should understand that the caution applies to the ship while at sea, or in docks.

(*By Mr. Darley.*) There is no great smell amongst the the coals. The smell affects you more about the head. If the hatches are blocked up, the danger would be explosion. I have not known of any such explosion while I have been employed.

JOHN BAXTER.

The within deposition of the said John Baxter was taken upon oath before me at the police court aforesaid this 26th day of September 1873.

D. MAUDE,
Stipendiary Magistrate.

GEORGE SAMUEL BAYLEY sworn.

I am a surveyor of shipping. I surveyed the "Berwick" steamer on the 15th of May last. I was requested to survey the ship by the coroner who was holding an inquest on the man who had been killed. When I went on board, the wreck of the woodwork of the forecastle had been removed, and a portion of the main-deck. I found that four beams of the main deck had been broken; and three frames, the angle iron frames, of the ship to which the beams had been attached also broken; the beams were on the starboard side. I think the angle irons were on the port side. The pall bit was broken, the iron deck over the water tank in the forepeak was forced down on the starboard side, and upwards on the port side; some of the rivets on the bulkhead were sheered off on the angle iron. One of the angle irons on the bulkhead was broken, and the corner of one of the bulkhead plates was torn. There was a stove in the forecastle for warming; it was not broken; the paint which remained on the pall bit and in the forecastle scuttle was not scorched or blistered. The only appearance of fire that I could see was a piece of newspaper that was blown in between the plate stringer and the deck planks on the port side close by the scuttle. The length of the forecastle was 29 feet; the store room at the afterpart of the forecastle was 9 feet long; the size of the forecastle scuttle was 2 feet 2 inches by 2 feet 5 inches. There was no communication between the store room and forecastle, except the small crevices in the seams of the deck. There was a pipe at the lower part of the bulkhead of the forecastle which communicated with the ballast tank, amidships; there were taps on that pipe, both open when I examined it. The pipe communicated with both tanks; both with the one amidships that was full of cargo, and the tank that is stated to have been empty. The explosion, I am of opinion, was in the forecastle, above the empty ballast tank. With the forecastle scuttle open, I should have hardly thought the gas could have accumulated sufficiently to cause an explosion. Had the gas accumulated in the empty tank, it could have escaped into the forecastle through two holes in the iron plate at the top of the tank. I cannot form an opinion of the cause of the explosion.

(*By Mr. Crossman.*) The pipe connecting the two tanks was below the flooring of the midship tank, which was a double floor. I am not satisfied that the explosion was that of gas.

(*By Mr. Maude.*) The lid of the empty tank was torn from its fastenings.

(*By Mr. Cottingham.*) Gas in a confined space would force itself through any aperture.

(*By Mr. Darley.*) There was a communication between the fore and after tanks by means of the pipe that I have mentioned. I was informed that coals had been stowed in the after tank. I think the pipe was about 3 inches in diameter in the clear, shewing a communication between the after ballast tank and the forecastle through the pipe and holes in the deck of the foremost tank—supposing the taps of the pipe to have been open. There was an iron deck to the midship ballast tank, with a hatch in the middle of it, open. If that hatch had been on, gas might have generated in the tank and forced itself through the pipe, provided the taps were open, into the forecastle. The depth of the after ballast tank was 7 or 8 feet. With the hatch off I could not say that gas would generate at the bottom of the tank and so force its way through the pipe with the pressure of the coals. The diameter of the sounding pipe for the empty tank was 1¼ inch. The lid of the empty tank had been risen 14 or 15 inches. The explosion had disturbed both decks.

(*By Admiral Powell.*) I am of opinion that the explosion was at the top of the tank, and not in the tank.

(*By Mr. Darley.*) The scuttle to the forecastle was rather on the port side, nearly amidships, close to the forecastle bulkhead, 2 feet 2 inches by 2 feet 5 inches. The length of the forecastle was 29 feet.

GEORGE S. BAYLEY.

The within deposition of the said George Samuel Bayley was taken upon oath before me at the police court aforesaid, this 26th day of September 1873.

D. MAUDE,
Stipendiary Magistrate.

WILLIAM FOX sworn.

I was chief engineer of the "Berwick," and was so on the 9th of May last. It was my duty to look to the pipe that leads from the fore tank to the after tank. I know it was all right on the voyage in question; the cock was open. It is the practice to keep the cock open when the ship is loaded. The cock is at the end of the pipe near the fore tank. I have not known gas to accumulate in the bilges of a coal ship; have never seen an accident from such a cause. There was a slight explosion of gas in this ship in 1867, but no damage was done; that was in the fore part of the ship, in a partition between the forecastle and the bulkhead that separates the cargo—the store-room as it is now. I was not on board at the time, although I was the engineer. It occurred in port in the Tyne. The cock would not be open at the time, I feel sure of that; as a general rule we open the cock on going to sea. I feel certain that the explosion was caused by gas. I think the weather has a good deal to do with it. At the time of the explosion the weather was very heavy. I was in my berth at the time. I saw the deck blown up; the lining of the forecastle was all torn, and the tank-top broken; there was a smell of burning. One man was killed and two injured.

(*By Mr. Crossman.*) There was a light and a fire in the forecastle at the time.

(*By Mr. Maude.*) There were marks of burning on the men.

(*By Mr. Darley.*) The pipe is not intended to communicate with the after ballast tank; it ends in the bilge underneath the tank. We have portable limber boards in the after tank; they are short, one is nearly over the end of the pipe. The limber boards are 5 or 6 feet long. There is a strum in the after part of the tank with a cast-iron cover to it. I do not think it possible for gas to have passed up through this strum. The hatches of the after ballast tank were off at the time of the explosion; all the hatches were off. There were coals stowed in the flat above the after ballast tank, pretty nearly up to the upper deck. From the top of the tank to the upper deck is about 6 feet.

WM. FOX.

The within deposition of the said William Fox was taken upon oath before me at the police court aforesaid, this 26th day of September 1873.

D. MAUDE,
Stipendiary Magistrate.

Greenwich Police Court, 27th September 1873.

JOHN HYDE sworn.

I am a seaman and was one of the crew on board the "Berwick" on the morning of the explosion in May last. I was aft on the quarter-deck when the explosion happened. I first heard the report and then I came forward and saw one man lying down dead, and some men were trying to get up out of the hatchway. I did not go into the forecastle then, not till ten hours afterwards. Previously to the explosion, about half an hour before, I lighted a piece of a paper by the fire in the forecastle; the lamp being out, I lighted the paper to make a drop of coffee. Morrison was lying on the port side along the timber heads, about 12 feet from the scuttle hatch. I did not notice any peculiar smell in the forecastle when I lighted the paper. Two other men were severely burnt.

(*By Mr. Crossman.*) When I was below lighting my piece of paper, Morrison was in bed. I then threw the piece of paper into the ashpan; it was nearly out.

(*By Mr. Maude.*) There is a sounding pipe leading from the tank below, which extends 3 or 4 feet above the deck of the forecastle, about a foot from the cupboard and 2 feet from the ladder. Where I threw the piece of burnt paper was 8 feet from the sounding pipe; that was half an hour before the explosion. I did not see anybody smoking in the forecastle. I did not light the lamp, I lighted the piece of paper to look for my pot to make the coffee. Morrison who was killed had a great habit of smoking his pipe of a morning before he came on deck. My impression is that Morrison must have struck his match to light his pipe upon this sounding pipe.

(*By Captain Powell.*) One hatch was off of every hatch, it being such fine weather.

(*By Mr. Darley.*) There are limbers in the fore hold. I have seen them up and have assisted in getting them up; they simply ship and unship; they are 4 or 5 feet long. I did not notice a pipe under these limbers. I have not seen the limbers taken up in the after tank. There was some paints and oils kept in the storeroom and some turpentine in a bottle, a tin bottle. The naphtha was kept there in a bottle also. There are two places in the after tank, one on each side, to let the water out of the tank. In one place it was 2 feet long, perforated with holes. It looked like brass. I know it was not wood; it was about 1 foot long, and the holes were the size of a little finger. On the other side of the tank the holes were about the same size, but the form of the plate was different—one projects above the flat, and the other is in the flat. I never saw that plate up, and cannot say where it goes to. There was an iron bulkhead on the fore side of the after tank; the aft bulkhead was also of iron. The limbers aft are from 2 to 3 feet of the bottom of the ship. I have never been down in those limbers, only to put my arm down to get the dirt out. If the hatches were on and the tarpaulines there would be no means, that I see, of ventilating the vessel whatever. I have assisted to load her on many occasions.

JOHN HYDE.

The within deposition of the said John Hyde was taken upon oath before me at the police court aforesaid, this 27th day of September 1873.

D. MAUDE,
Stipendiary Magistrate.

FREDERICK ROGERS sworn.

I was a fireman in May last on board the "Berwick," and was on board on the morning of the 8th. I was in the forecastle when the explosion occurred. I did not hear the explosion. I was sitting down in the middle of the forecastle. I was burnt suddenly about the neck and arms. I did not smell anything. Morrison was coming out of the forecastle at the time; he was on the forecastle ladder. I did not see him light anything. I did not see him smoking his pipe. The third man who was hurt was in his hammock, 10 or 12 feet from the scuttle on the port side. I know that Morrison often lighted his pipe; he was in the habit of lighting his pipe before he went on deck of a morning; he mostly struck a match. I know where the sounding pipe is in the forecastle; I never saw Morrison strike his match on that pipe. I have seen him strike a match close by that pipe on a match box, as he kept his matches in a locker close alongside this pipe. I have seen him light his pipe at that locker; he would throw his match on the forecastle floor. I did not see him light a match on the morning of the explosion. He might have lighted one without my seeing him on that morning. When I got on deck Morrison, I found, was dead on the deck. I did not go into forecastle any more.

(*By Mr. Crossman.*) I went into the forecastle to call Morrison. I did not smell anything, nor did I see any flame.

(*By Mr. Maude.*) A man going up the ladder would pass by the pipe, which would be on his right hand, and he might easily have rubbed his match upon that pipe while passing up.

(*By Admiral Powell.*) I did not see much smoke in the forecastle.

(*By Mr. Darley.*) I had only been a week in the ship, one voyage. I was never in any of the holds. I never cleaned out the limbers, either aft or forward.

FREDERICK ROGERS.

The within deposition of the said Frederick Rogers was taken upon oath before me at the police court aforesaid, this 27th day of September 1873.

D. MAUDE,
Stipendiary Magistrate.

WILLIAM CLARKE sworn.

I was second mate of the "Berwick" in May last, and was present at her loading with gas coal. There is a warning posted up not to batten the hatches down while the ships are loading. I complied with that notice. The "Berwick" has five water-tight compartments, four holds for cargo; the first forward is a ballast tank, and is always used for that purpose; No. 2 is a store room; No. 3 is the fore hold for cargo; No. 3 is not used as a ballast tank; No. 4 is used as a ballast tank; there is a difference in the ceilings of Nos. 3 and 4. The ceiling of No. 4 is double all over. No. 4 is used for cargo as well as ballast. No. 5 is used for cargo only; the ceiling of No. 5 is the same as No. 3, a single lining, but since the explosion a double lining has been put on, making it the same as No. 4. That was done because the ceiling was bad and allowed the coal dust to get into the bilge. There is a pipe leading from the ballast tank under the forecastle. I do not know how far it leads aft; it leads into the bilge. When the bilges get water in they are pumped out by the engine. I was in the ship in 1867. There was a slight explosion then in the store room, but no injury was done worth speaking of. That occurred in the Tyne Dock. That occurred by a man taking a naked light into the store room. The gas must have got in through the wooden bulkhead. Ever since that time it has been strictly forbidden to go into the store room with a naked light, that is to say, if the ship is loaded. Our hatches were off at the time of the last explosion. I was in my bed at the time and felt the shock.

(*By Mr. Crossman.*) The ceiling of No. 5 was repaired in consequence of injury received in unloading the ship.

(*By Mr. Cottingham.*) No alteration has been made in the ventilation of the store room since 1867. The hatch of that compartment was off at the time of the last explosion.

(*By Mr. Darley.*) I have been seven years in the ship. Before the explosion the only way of ventilating the ship was by taking the hatches off. Since the accident two ventilating pipes have been placed in the fore hold, about 5 inches in diameter. There are four pipes been fitted to No. 4 compartment, the ballast tank, and two in No. 5 compartment; also two in the store room and two in the forecastle, which go down into the tank. There are also two ventilating pipes in the forecastle which do not go into the tank.

WILLIAM CLARKE.

The within deposition of the said William Clarke was taken upon oath before me, at the police court aforesaid, this 27th day of September 1873.

D. MAUDE,
Stipendiary Magistrate.

WILLIAM PARKER sworn.

I am steamship surveyor to the Board of Trade. On the 2nd August last, by direction of the Board of Trade, I surveyed the S.S. "Berwick," which was lying in the Regent's Canal Basin; her cargo was out. I made a report of the survey which I now produce, and it is correct. (Report read.) I am of opinion that the bilge would hold a sufficient quantity of gas to fill the tank and more; a portion might be drawn into the engine-room; from what I saw my opinion is that the explosion took place in the tank, and would rush out through the scuttle of the forecastle. I traced the pipe into the bilge. If gas accumulated in any of the compartments it would flow through the entire bilge.

(*By Captain Powell.*) The sounding pipe when I saw it went up to the upper deck. I would not pass a passenger ship with the sounding pipe coming into the forecastle where the men lived, unless it came to the main deck.

(*By Mr. Crossman.*) In colliers it is the general rule for the sounding pipes to end in the forecastle. We have no jurisdiction over colliers in that respect.

WM. PARKER.

The within deposition of the said William Parker was taken upon oath before me at the police court aforesaid, this 27th day of September 1873.

D. MAUDE,
Stipendiary Magistrate.

ADOLPH VASSARD sworn.

I reside at No. 25, Finsbury Place, London. I am a member of the Chemical Society of Paris, also of the Polytechnic Society, Paris. I have analysed a sample of coal sent to me by Mr. Johnasson, the owner of the "Berwick." I produce a portion of that sample. I have sent in a report of that analysis, and now produce it. (Read.) I have no doubt that the explosion took place at the mouth of the pipe in the forecastle under the ladder. The report of the explosion would be very low.

A. Vassard.

The within deposition of the said Adolph Vassard was taken upon oath before me at the police court aforesaid, this 27th day of September 1873.

D. Maude,
Stipendiary Magistrate.

Report of Adolph Vassard (referred to in his evidence).

I have no doubt that the cause of the explosion that took place on the "Berwick" was due to light carburetted hydrogen gas, otherwise metham, fire damp or marsh gas. This gas is but too often disengaged in coal mines from freshly cut surface or from apertures or blowers where it exists in a state of compression, or from the cells of the coal thrown open by the breaking of the coal. It produces all the accidents resulting from explosions in collieries. It is the result of the decomposition of wood or brom coal into mineral coal and is constantly formed by and disengaged from coal that has not yet attained the highest degree of decomposition represented by anthracite or stone coal. Of course it is so formed and disengaged in more or less quantity according to the actual state of the coal, that is to say, according to a graduate scale beginning with cannel coal and ending with anthracite.

The specific gravity of that gas is 0·559 or little more than half that of air. It is colourless and inodorous, and can be respired to a great extent without danger. When it comes into contact with air and a naked light, it at once explodes and produces carbonic acid gas, with the same effect as gunpowder.

Its illuminating power is very low, and it burns with a pale yellow flame.

It is a mixture of that gas and of carbonic acid that is given off when the bottom of pools in which water plants grow is stirred up.

I have examined the coal furnished to me by the owner as being similar coal to that which was on board the "Berwick" when the explosion took place. It consists of about one-third of highly bituminous coal and two-thirds of fine cannel coal. It well deserves its name of gas coal.

Some pieces of the coal are very curious, and show to actual demonstration that it is actually in course of further decomposition. It must be here remembered that cannel coal is the intermediate state of coal between wood coal and bituminous coal. Its decomposition is actually going on with large emission of light carburetted hydrogen.

The bituminous part of the cargo on board the "Berwick" was brittle and easily broken, and it may have been broken by the attrition of the ship; opening some cells and giving off its share of gas; but the great source of carburetted hydrogen was the cannel coal.

In four days a weighed quantity of that coal, broken up, gave me a quantity of the said gas equal ¾ of a cubic foot per ton.

Upon analysis the mixed coal gave me—

Carbon - - - -	64·72
Hydrogen - - - -	21·56
Oxygen and Nitrogen - -	11·92
Ash - - - -	1·80
	100·00

It gives 13·549 cubic feet of illuminating gas per ton, or nearly 462 lbs.

Its specific gravity is 1·272. The nature of the gas that to my belief produced the explosion having been explained, it can be understood that on a steamer loaded with a large quantity of such a kind of coal so liable to emit it, a rather large amount of carburetted hydrogen will be given off, and if no or inadequate escape is provided for it, it will find its way into any empty part through any leakage or pipe to be found.

Moreover, if, as I understand it to be the case, on board ship carrying coal all available room is used, if the bilge was not actually filled up with coal, at all events some was close by the side of it or immediately over it or part of it, and though the gas is lighter than air it may nevertheless have been forced sideward or downward into the bilge where there, finding the leaden pipe leading into the ballast tank, of course it took that way. Although that pipe is provided with a cock to prevent the escape of water when the ballast tank is filled, it may certainly have been left open, not being actually wanted for the purpose which it was fitted for, because the tank was empty.

Therefore, it can be assumed that that cock was left open; that the carburetted hydrogen gas went through the lead pipe into the ballast tank, and there finding its way through the air pipe it went through it. That pipe, the evidence shows, had its opening immediately under the ladder of the forecastle, therefore a current of gas, carburretted hydrogen, was continually existing under that ladder.

The first man who went down the forecastle may have lighted his newspaper when on the bottom, without thinking, however, that he was not doing the best for his safety. The deceased, very likely, lighted his match, piece of newspaper, or whatever it may have been, while actually going down the ladder, whereby his naked light came into contact or nearly so with the opening of the air pipe, therefore with gas (carburetted hydrogen), and necessarily an explosion took place which was communicated at once to the inner part of pipe and tank, and did all the damage.

In conclusion though, there are anthracite and chemically agglomerated coal dusts that are not liable to give off carburetted hydrogen, it is necessary on board ship carrying coal of any kind to provide for a thorough ventilation of the whole cargo, and to take every precaution against the escape of inflammable gases through pipes or into places where they ought not to be found.

(Signed) A. Vassard.

Exhibited before me at the police court aforesaid, this 27th day of September 1873.

D. Maude,
Stipendiary Magistrate.

Report of Mr. William Parker, Board of Trade Surveyor.

Board of Trade Surveyor's Office,
St. Katherine's Dock House, Tower Hill,
August 5th, 1873.

I have inspected the ss. "Berwick," official No. 6131, and have the honour to report as follows:

The vessel is 183 feet long, divided into six compartments by five iron bulkheads. In the first and third of these compartments iron 'tween decks are laid, and the lower parts used for water ballast.

In the first compartment and directly under the lower forecastle the explosion took place, tearing away from frames the whole of the iron deck from bulkhead to stem on the port side, bending and breaking nearly all the beams, and breaking three of the main deck beams above.

I have carefully examined the bulkhead dividing th tank from the hold and cannot conceive how gas could escape through it; further, I had it filled with water and found it perfectly tight. But I beg to call your attention to the pipe for running the water out of this tank; it is a 2½-inch pipe leading from lower part of tank to bilge in No. 3 compartment, and can be opened or closed by means of a cock attached to the bulkhead. The tank is always empty when the vessel is loaded, and if this cock had been left open, all the gas that accumulated and found its way into the bilge would flow into the tank, and considering it would not be required to be closed until the vessel was discharged and tank ready for running up, I think it likely it was left open.

I have further to observe that the only air pipes in the ship for the escape of gas were the sounding pipes, 2 inches diameter, which as usual were covered over on deck. The one that led from forward tank being alone open to the forecastle, and in such a position that a man going up the forecastle ladder could easily drop a lighted match down.

Since the explosion each compartment has been fitted with two 4½-inch air pipes, and the sounding pipe in forward tank carried above main deck.

This morning I intended examining the inside of forward tank so that I could satisfy myself there had been no other air pipes, and that bulkhead had not been repaired since the explosion, but when I got to the dock found vessel had sailed yesterday.

(Signed) William Parker,
Surveyor.

Exhibited before me at the police court aforesaid, this 27th day of September 1873.

D. Maude,
Stipendiary Magistrate.

The Report.

The "Berwick" was an iron screw steam ship, built at Cartsdyke, in the county of Renfrew, in November 1855. She had two decks, three masts; was schooner rigged, of 365 tons register, and the joint property of Messrs. George Elliott and David Johnessohn, of Usworth Colliery, in the county of Durham, colliery owners.

The "Berwick" was one of a fleet of steam ships solely employed in conveying coal cargoes, and made on an average from 45 to 50 voyages a year from the port of Shields to London and elsewhere.

She left Shields for London on the 8th of May last under the command of Mr. Robert Brown, who holds a certificate of competency as only mate, dated the 4th of July 1868. She had a cargo of 732 tons of gas coal on board. On the following morning (the 9th) at 4 o'clock the Dudgeon light was passed; at 5 a.m. a thick fog set in and the engines were eased to half speed. At 6 a.m. an explosion took place in the forecastle, and one of the stokers, John Morrison, who was at the time coming up the forecastle ladder, was blown some 14 feet into the air and killed, and two other firemen who were in the forecastle were much injured.

From the evidence it appeared that the "Berwick" was 183 feet long, and divided into six compartments by five bulkheads. In the first and fourth of these compartments iron 'tween decks were laid and the lower parts were used for water ballast. The first compartment, which was immediately under the forcastle, was used for water ballast only, the second compartment was used as a store room, the third for cargo, the fourth was a ballast tank and used also for cargo, and the fifth for cargo only. On this voyage the forward tank was empty, as was usual when the ship was laden; from this tank a discharge pipe led to the bilge under the after cargo hold; the cock of this pipe was, when the tank was empty, always left open. There was also a sounding pipe to this tank which terminated in the forecastle about 3 feet from the deck, and by the side of the hatch; this was an open pipe. There was also a rivet hole left open in the deck-flat to allow water to pass from the deck into the tank. The Court thus traced a direct communication between the bilge through the tank into the forecastle, where the explosion took place. It appeared in evidence that the coal shipped emitted a gas, although inodorous and not detrimental to life, and was highly explosive when brought in contact with flame.

Although the evidence is not entirely conclusive on this point, the Court have every reason to believe that the man Morrison, either by a lighted pipe or match, ignited the gas that came up from the sounding pipe, thus blowing him up through the hatchway and causing a lesser injury to the other two men who were at the further side of the forecastle.

The Court, after a careful consideration, exonerated the master of all blame, and returned to him his certificate.

It appeared by the evidence than an explosion took place in the forward store room of the "Berwick" in 1867, and there is every reason to believe that it arose from the ignition of similar gases; no one was then injured, and the damage done was trifling. The owners, however, very properly ordered the Davy lamp to be used in future in the holds and store room.

The Court would suggest that the following precautions should be taken in vessels carrying coal cargoes, viz.:—

That the discharge pipes from the water ballast tanks should not terminate in the compartments where explosive gas is likely to collect, and that all sounding pipes should be carried to the upper deck.

Also that arrangements should be made by pipes or other means to ventilate the lower part of the holds of vessels where gas is likely to accumulate.

The Court also attach the utmost importance to excluding fire damp or gas from the compartments where the crew live. This requires not only great care on the part of those who survey the ship, but the constant supervision of the master.

D. Maude,
Stipendiary Magistrate.

We concur in this report,

R. Ashmore Powell, } Assessors.
Wm. Darley,

The following Memorandum on Gas Explosion, drawn up by Mr. Darley, Nautical Assessor in cases of the "Zeno" and "Berwick," at the request of the Board of Trade, has been forwarded to the Commission by that Department.

To T. H. Farrer, Esq., Secretary of the Board of Trade,
&c. &c.

12, Batsford Road, St. John's Road,
Deptford, S.E.,
14th August 1875.

Sir,

In compliance with your request I have great pleasure in submitting the following memoranda and suggestions with reference to casualties from gas explosions on board colliers, observing that I shall be happy to aid you or the Royal Commission in any way you may desire.

I am, &c.
(Signed) W. Darley,
late Nautical Assessor.

To prevent Gas Explosions.

In a few words, to prevent accumulation of gas in confined spaces, and to command a free current of air to liberate it, has hitherto proved the most successful, and as a general rule explosions have taken place where this has not been attended to.

Great danger arises from the too hasty transfer of *green* coal just taken from the mine to the hold of the vessel; in this condition it is most gaseous, and hence the greater the danger; and although this applies to coal generally, it does particularly so to the Welch coal from Cardiff.

In order, therefore, to reduce the danger, it should be exposed to the atmosphere some seven or eight days previous to being shipped, but kept free from rain.

On being shipped, it will continue to emit gas, and more from heavy motions of the ship than when at rest; the tendency in the former case being to break the coal, and thus open the cells, and allow the escape of gas.

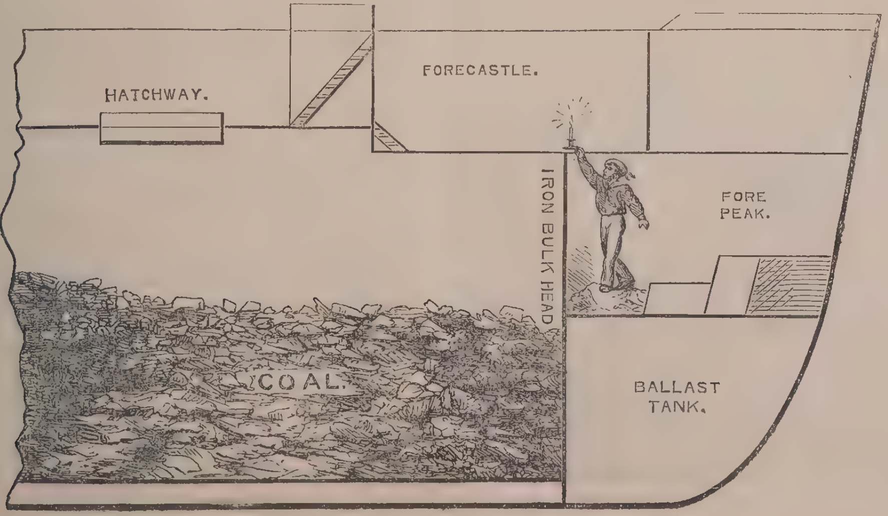
The specific gravity of gas being considerably less than atmospheric air, it naturally rises to the deck, and fills the space between the coals and deck; it also forces its way through any bulkheads to compartments adjacent to these in which coals are stowed, naturally in every case rising to the upper part of the vessel.

This was shown in the case of the "Zeno," where the forepeak, the fore side of the coal-hold, was made a receptacle for the gas, and in which the explosion took place, bursting the deck, the foremost bulkhead, and the bows of the vessel, by which in 50 minutes 33,000*l.* worth of property was destroyed, and 29 men placed in peril in the Bay of Biscay.

The accompanying sketch will give an idea of how it occurred.

The explosion in this case occurred through a man going to the forepeak with a naked light. He removed the hatch and went down and took the light in his hand. As soon as it was brought below the deck the explosion occurred, blowing him into the bows of the vessel.

"Zeno."



I would remark that it appears to me that an action takes place from the point of explosion as a centre. In this case the man was blown down into the bows; in the case of the "Berwick" the man who was the cause of the explosion was blown into the air and killed. This appears to arise from the act of stooping to strike his match to light the pipe, when the explosion took place below him and blew him up.

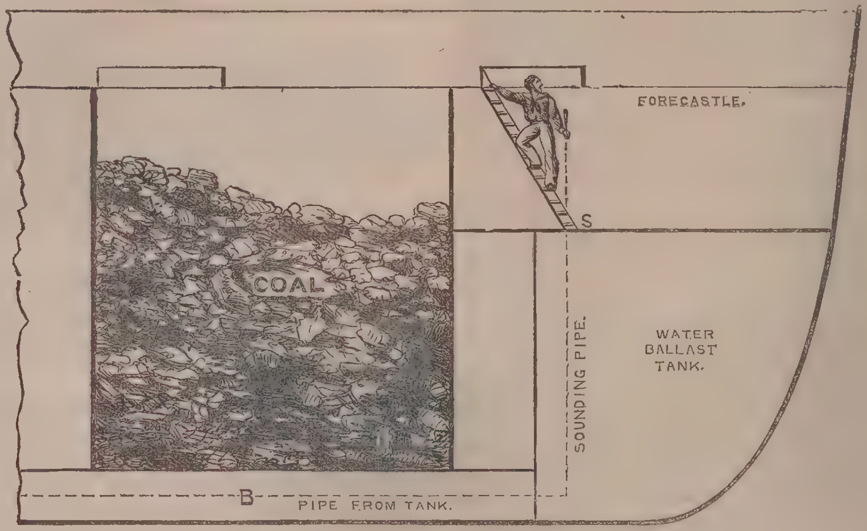
In each of these cases the gas was confined and no ventilation provided.

From the explanation given at the court at Hull on the "Zeno," she was built for a general cargo, and in this exceptional case was used for a cargo of Cardiff hard, brittle coal, shipped very green and under unfavourable circumstances, the weather being very foggy at the time.

The case of the "Berwick" was one in which the fore ballast tank was made the receptacle for the gas, fed by a pipe leading from the bilge in midships. At the upper part of the tank was fixed a sounding pipe, from which the gas as it escaped came into contact with the light and produced the explosion, as the man descended the ladder, of which the following sketch will give an idea, the light being produced from a match with which he was about to light his pipe.

There were two evils connected with this vessel, viz., the dangerous termination of the sounding pipe, S, between decks, instead of being led to the upper deck, and the pipe from the tank to the bridge, B, terminating in midships, instead of being led aft to the bilge of the engine-room, clear of the gases.

"BERWICK."



On the sounding pipe, S, ending between decks it would lead the gas into the forecastle, and make that a receptacle.

The pipe, B, leading into midships brought it in contact with the gas generated from the coal, formed a passage for the gas to the water ballast tank, and hence the fatal consequences.

The fact of the vessel being thus attended with such results suggest that no coal vessel should be allowed to proceed to sea in such an unseaworthy condition as the best means to prevent casualties from a similar cause.

The drawing which I forwarded to the Board of Trade, by request of the court at Hull, contained a comprehensive system of ventilation, which is applied with such success in the Royal Navy that such a thing as gas explosion is unknown in the service, and not only applies for the purpose of dispersing gases to prevent casualties, but also for sanitary purposes, to carry off foul air.

I would remark that it is necessary at least two cowls be fitted to each compartment which it is desired to ventilate, the one as a downtake, the other as an uptake. One drives the cold air down, the other allows the heated air to ascend.

The gas and impure air will thus be incessantly driven out as it is generated.

Whilst these shown in the drawing are the most effective, others less expensive may be fitted to answer the same purpose; but the fatality of so many vessels from this cause renders it imperative, for the safety of life and property, that some such means should be resorted to, which, however expensive, is cheapest in the long run.

In wood vessels the openings between the timbers may be used to great advantage for the purpose of ventilation, and a strake of plank left open or hinged, so as to admit of being opened at pleasure, the fillings between the timbers and chocks being left out in some cases, will afford means also for ventilation.

Perforations or holes cut through the bulkheads at the upper part will allow of a free passage of air from one compartment to another.

The bitts, mast wedges, mast (iron) hatchways, funnel casing, ballard heads, and other fittings present facilities for ventilation, which, if used, provide excellent means for liberating the gases and preventing danger.

I have hitherto referred to the means of escape aloft; I would now direct attention to those which may be resorted to below, in order to prevent the heating of the coals, and to admit of a freedom of the escape of gas from the lower part of the coals.

The cargo may be divided in midships by two planks, one on each side of the pillars, the plank being fixed Venetian way, or perforated, so as to allow the gases to escape between them.

The same course may be taken athwartships, where it is desirable, by placing chocks or quartering between the plank, allowing the gases to escape.

Particular care should be taken to well ventilate those compartments adjacent to the coal-holds, which from the leakage of bulkheads, are likely to mislead into danger by the impression that because there is no coal there is no danger; the cases both of the "Zeno" and "Berwick" showing that the danger lay where there was no coal.

I cannot speak in too high terms, nor do I think too much importance can be attached to the use, of the Davy lamps on board colliers. There is the same gas and the same danger on board ships as in the mine, and therefore I think it would be both wise and humane to make it compulsory to use them.

They were used on board the "Berwick."

I would recommend that testing tubes be fitted leading from the deck to the lower part of the hold, so that periodically, by the aid of a thermometer, the heat of the coals may be ascertained, the lower parts of these being kept a short distance from the bottom will allow of much of the gas escaping; these may also be perforated at the sides, which will further liberate the gas.

There is an objection to use wood pipes, which are commonly fitted, from their tendency to forward spontaneous combustion, from the fact that the wood will take fire at a much less temperature than coal, and being the practice to put them in the main hatchway where the small coal is deposited, the pipes first get dry, then the point of ignition is reached.

They convey air to fan the smouldering wood into a flame, and afford means for the fire to spread.

In the absence of the wood pipe, the coal disposed to heat would take a longer time.

If pipes of iron, perforated, be placed in the coals, they should be fitted vertically, and not at the lower part of the cargo, to come into contact with water.

Earthenware pipes may be used to advantage, laid horizontally at the lower part, and in the centre of the cargo.

The galley funnel, from its heat, would act favourably upon a pipe led up at the back of it, the heat having a tendency to draw the gases up.

Advantage should be taken of fine weather to open the hatches, and wind-sails may be used.

Arrangement should be made to ventilate the limbers and under the flats of the holds, and that good arrangement be made for pumping in the event of a leak. It is a matter of importance, with the view of preventing spontaneous combustion, that the cargo be shipped dry, that is, in dry weather, and that it be kept dry during the voyage.

There is much more risk with small than large coals, and it will be found that fires originate generally in the middle of the cargo under the main hatchway, where the greatest portion of the coal dust lies.

Coal having large quantities of iron and sulphur in their composition, being deposited in large quantities and not kept perfectly dry, are liable to spontaneous combustion, as a chemical action takes place, and ignites the coal, from which many vessels are lost.

(Signed) W. Darley.

"MIRANDA."

Official Inquiry held at the Town Hall, Cardiff, on the 13th September 1875, before R. O. Jones, Esq., Stipendiary Magistrate for the borough of Cardiff, assisted by Captain Castle and Captain Pryce as Nautical Assessors, respecting a casualty which happened on board the steamship "Miranda" off the coast of Cornwall on the 26th August 1875.

The Evidence.

Peter Peterson.

I am chief mate of the "Miranda"; joined her at Waterford in the beginning of June. I went from thence to Cardiff and Malta. Arrived at Newport on Friday, 20th August last, in ballast. Began to load on Saturday, the 21st. It was my duty to see to the loading. When we began the holds were quite clean and all swept out; no damp or wet in them to my knowledge. Her forehold, mainhold, and afterhold were divided by iron bulkheads. Completed loading on Tuesday evening, between 5 and 6. The coal was all supplied by the same merchant, so far as I know. There were the same marks on the waggons. P. D. were the marks on the waggons. While loading we had wet weather; it was raining on Tuesday, and was raining on Tuesday night. The hatches were not on. The three hatches were loaded at different times; the afterhold was loaded first; part of the mainhold was loaded first, then the afterhold was finished, the forehold being loaded last. It was showery all day on Tuesday. We were not altogether engaged on the forehold on Tuesday, but finished loading between 5 and 6 on Tuesday evening, and went out of dock at noon on Wednesday. When we left the dock the hatches were put on, but one or two on each hatchway was left off. The main hatches and fore hatches went right across from coaming to coaming. The after-hatch was divided. The weather when we got out channel was a strong breeze going down channel from the west. At half-past six p.m. we battened down the hatches. I have been for the last five years in coal-carrying vessels, and for some time before. This cargo was properly stowed. There is no ventilation in the vessel in the fore and main hold. The main hold was full, close up to the deck, and the forehold there was a portion left out on account of trim, a space between deck and cargo of, perhaps, 2 feet; it was not trimmed flat. There was no communication between forehold and forepeak; they were divided by collision bulkheads, which I considered water-tight. It extended up to the forecastle floor. There was a hatch in the forecastle to get down into the forepeak—a small hatch, right forward. From 6 p.m. till we got to St. Ives Bay it looked like bad weather, and I thought it prudent to batten down the hatches. There was a strong wind and heavy sea. Spray came over. We removed one of the hatches of the mainhold on Thursday, at 9 o'clock a.m., to let out any gas. None of the crew had complained. The boatswain told me in the morning it was dangerous coal, but did not complain that the hatches were battened down. When we took off the mainhold we did not discover any smell of gas. The other hatches were kept on. On Thursday, 26th, my watch began at 8 a.m. up to 12. Nothing particular occurred. There was a ventilation to the afterhold of iron. I noticed during my watch that the carpenter was repairing the bell. When my watch ended I went on the bridge. There was no light to my knowledge in the forecastle at that time; did not order any down into the forepeak. There was a lot of stores there—rope, oakum, &c. There was nothing but oakum and pitch there for the carpenter. Soon after 12, when on the bridge speaking to the captain, there was an explosion. When I saw the flame and pieces flying I went behind the funnel. The vessel was going at that time about 5 knots, her full speed. After the smoke cleared I saw the whole ship was blown up forwards, and we at once went to get the boats ready; that did not take long. The vessel was on fire. The captain ordered the engines to be stopped at once, that was the first order he gave; then we got out boats and called for the carpenter to mend the pumps. There was no reply. I asked the chief engineer to set on the donkey engine to put out the fire, which was at once done. We were about half an hour extinguishing the fire. After the report the flame went up as high as the topsail yard, and everything went before it. First saw the carpenter on the poop. The foredeck was entirely blown off. I think nine beams were broken, some in two, and the deck blown up past the foremast, and the forecastle blown up. The damage did not extend quite to the mainhold. A small hatch belonging to the mainhold was off—a separate hatch. I saw some pieces of tarpaulin burning aloft. Some of the ratlines blown off the bulwark was blown off, the first plate down. The explosion had opened the ship. The explosion went up and lifted the stronger plate and bulged the ship out. The bulkhead between forehold and mainhold was damaged; was blown aft 4 or 5 inches, bent. The ship is now in the Hill dry dock. After the explosion, first saw the carpenter on the bridge; he was very much burnt. His hair and beard were burnt off; his clothes were in rags. I spoke to him. I said, "Lie yourself down on the poop." I said, "Have you had any light." He said, "No." I asked him where he had been first. He said he had been down forward; whether forecastle or forepeak I do not remember. I afterwards heard the chief engineer ask him where he put the light. He said, "On the seat, and when I took off the hatch it blew him down the forepeak." When we called over the crew Benjamin Davies was missing. The carpenter told us there was one man missing, he did not say whom. Davies was in my watch. There was one more of the crew hurt. I can form no opinion of the cause of this accident. I should think it would be the naked light. I suppose gas got into the forepeak. No notice or instruction about ventilation had been given to us before leaving Newport Dock. There are no regulations there that I know of. I have loaded a cargo of coals at Cardiff. Never observed any notice there about the explosive nature of the coal, or about ventilation. Of my own experience it is always necessary to take off hatches when the weather permits. The ventilator passes through the deck in front of the poop, and goes up about 8 feet. That was the only means of ventilation.

(*By Mr. Vachell.*) It was in my opinion a prudent thing to batten down hatches at 6.30. We shipped water during the night. The look-out was stationed that night on the bridge, not on the forecastle, because of the sea. There was rain, and it was blowing hard during the night. The next morning we took off one hatch. If we had taken one off the fore hatchway we would have shipped water down. At the time of explosion vessel was heading S.W. ½ W., and the wind was about W.S.W., a head wind, a little on the starboard bow. At the time of explosion we were off St. Ives Bay. It would have taken about one hour and a half to get round the land to the open. Having rounded the land the vessel would have headed about S. by E. We should have had a fair wind. Having a fair wind we should have taken our hatches off. The ventilator goes right down to the bilge. It goes to the pump and down. The ventilator is the pump itself. There was a Davy lamp on board the vessel. It was not prudent to take the hatchway to the forepeak off with a naked light close by. There was no light to my knowledge in the forecastle up to 12. When the men go to bed they would have a naked light. I had been on board this ship when she had taken a cargo of coal.

Re-examined by Captain Castle.

We had mooring bits, two forward and two aft, and two on poop, of iron. They were not fitted as ventilators. I have seen them so fitted in new ships; there was a sluice valve in the collision bulkhead, shut when I saw it; carpenter had charge of it. The hatch was left off the night we loaded to let any gas accumulated go off. It was against all orders to take naked lights below; no one goes down without orders. If I had sent anyone down I should have given him orders not to take a naked light. We had no lock to our forehatch. Anyone could, I suppose, go down at any time they pleased. I had not given them any orders then. The hatch in forecastle was flush with the deck. There was nothing to stop it going up if there was any pressure.

(*By Captain Pryce.*) Our engines were amidships, and our foremast was immediately before the bulkhead separating the fore from the main hold, the end was parted off under the hatchway, probably trimmed into the wings, but at the fore and after ends there was a space. The seat on which the carpenter stood the light was 20 inches above the deck and about 2 feet from the after coaming of the fore scuttle. The forecastle did not require a lamp in the day time; at night it hung nearly amidships in the sailors compartment of the forecastle; but a little abaft the forecastle. The deck over collision bulkhead was of wood. The carpenter kept his nails &c. aft.

Edward C. Downing.

I am a coal merchant and shipbroker at Cardiff. I have had upwards of 30 years' experience of the nature of steam coal, and give attention to the stowing of steam coal and its dangerous qualities. Coal of the Lower Duffryn, Middle Duffryn, Abergavawr, Fontaman, Cwm Rheol, Aberuman collieries are of the same quality. Coal recently taken from the colliery contains more gas than that longer exposed to the air, and coal recently taken would require more care in shipment and ventilation. Coal stowed in a vessel in a wet state would not be liable to give out more gas than coal in a dry state. In coal liable to spontaneous combustion the damp would produce it, but such a combustion has never taken place in coal of the kind. In a vessel loaded as this was it would be most dangerous to put to sea without proper precautions as to ventilation in the case of coal battened down.

[Mr. Downing's evidence was interrupted in order that the witness Dunn might be called to speak as to the collieries from which coal had been raised.—(Signed) D. Rees, Justices' clerk.]

John Dunn.

I am foreman at Newport of the Powell Duffryn Company. I know what coal was shipped in August last in the steamship "Miranda."

	Tons.
Fontaman - - -	136·6
Lower Duffryn - -	395
Abergwawn - -	121·13
Middle Duffryn - -	405·1
Aberaman - - -	228·4
Cwm Rheol - - -	414

Altogether, 1,694 tons 4 cwts. 115 tons of screening were extracted. The nett quantity put on board was 1,579 tons 4 cwts. I saw part of the coal put on board. I believe the coal was very dry when put on board. From the invoices I have got, I can say that the coal had been about 24 hours out of the colliery, a little of it might have been longer.

(*By Mr. Vachell.*) I do not know what seam the coal came from like this, the air would in a very few hours be in a most dangerous state. It is usual to ventilate the holds of vessels loaded with coals of the description. The precautions are necessary in every hold. I should not think that gas would accumulate more readily where there is a space left in loading above the coal. The usual means for carrying off gas is to put the hatches open and pipes passing through the deck so as to create a current of air over the coals. I should think it most incautious in a master to batten down his hatches in a few hours after going to sea.

(*By Mr. Vachell.*) I know what kind of ventilators are put in vessels whose loading I superintend. I recommend the captains not to put wooden pipes. I might say the majority have iron ventilators of some kind. The ships I superintend generally take long voyages. A ship going to Bridgewater would equally require a ventilator with those going long voyages. I have known many explosions in dock in my experience. It is not usual to give notice to captains whether coal is recent or not from the collieries.

(*By Captain Castle.*) The tubes to take off the gas would be small 9-inch. I am not aware that mooring bollards are used as ventilators; iron masts are often used.

(*By Captain Pryce.*) Shown the plan. I should think it imprudent to have the hatches battened on before 12 hours, the coal being stowed as pointed out.

Thomas Dunn.

I am A.B., living at Newport, and shipped in the "Miranda" on the Monday before she left Newport. I shipped as fireman. She was loaded in the Alexandra Dock. There was one bit of a shower while loading. The forehold was the last loaded. The after-hatch was loaded first. I did not join till Wednesday about half-past 11. When she was in the basin the loading of the forehold had been completed, and was chock full up to the deck. All the hatches were battened down except one hatch on the forehold. Before we got outside the mouth of the river the forehold was battened down. That was done by order of the second mate. After that was done, order was given to wash decks. At that time all the hatches were fastened down. The carpenter secured them by order of the second mate. They were all battened down just as we got outside of the river. While I was on deck not one hatchway was opened, not even the little hatchway forward. I heard the boatswain grumbling about the hatches being battened down; we all grumbled. On the day after we left Newport my watch was from 8 to 12. During the watch I saw the carpenter about 10 o'clock; he was going to fix my bunker boards. At 12 o'clock I came up on deck, and just as I got to the forepart of the bridge away she went like the shot out of a gun. I was going forward. When the explosion took place we went to the boats, every man for himself; no one gave orders; all were cutting away the boats. I first saw the carpenter on the poop; the captain was putting oil over him and Jim James. After the smoke cleared, the captain gave order to put the hose on to dout the fire. After that I saw the captain putting oil on the men. Seven of the crew were English, the rest were Swedes. Benjamin Davies was killed by the explosion. Jim James was hurt, and the carpenter. We did not get our boats into the water.

(*By Mr. Vachell.*) The coal in the forehatch was shipped between 4 and 5 in the morning. We were there about 6, and then were told that the ship was not going out, so we went away. It was not raining at all. I was on deck when the ship went out of the basin. I have had no row with the chief engineer. After we got outside the Newport light there was no hatch off at all till it was it was blowed away. I did not complain to the captain about the hatch, it was not my place. I cheeked the boatswain about it.

(*By Mr. Waldron.*) I was sitting on the forehatch while we were going down the river. It was all down then. We got from the forecastle to the forepeak by a trap hatch; it was open two or three times. A man named John went down to the forepeak to look after his knife.

William Smith.

I was boatswain of the "Miranda." I signed articles on the 23rd August, Monday. I went on board on the Wednesday about half-past 10 in the morning. The vessel had completed loading, and was in the lock. She left Newport about half-past 11. We went down the river, it was blowing rather fresh. All the hatches were on except one hatch of the forehatch which was left off. That was fastened down about half-past 7 that evening. We were then below the Nash. When we got out of the river orders were given to clean the decks. I assisted. We began at the fore part of the vessel; we coiled the ropes away first. The middle hatch was entirely closed; the forehatch was open then, and I went down to the forehold to get some lines. That forehatch was not fastened down till we got below the Nash. The hatch was put on about 4; it was not battened down till half-past 7. From that time none of the hatches were opened. On the Thursday my watch was from 8 to 12 in the forenoon. I did on that day sound the bell at 12 o'clock by order of chief mate. The carpenter was working at it; the bell was lying on the middle hatch, and the carpenter said to himself, "I'll get a bit of wire to fasten the bell." He went to the forepart of the vessel. I went to my berth amidships, and was there about a minute when I heard a report, and went out and saw pieces of wood falling about. I was struck. I and all hands getting the boats, and went up and assisted. The forepart of the ship was blown up, and the hatch, and started the winch and blew the beams away, and the main deck as far as the foremast was started. There was a leak on the port side, and I shoved a sail in. I saw the carpenter come on the bridge holding his hands out and singing out. He went on the poop, and they put an awning over him. I had seen Davies that morning, the last time about two minutes before I went to my berth. He went to the foremast of the ship. After the explosion I picked up pieces of his cap on the poop. I heard the captain ask the carpenter if he had a light, and he said "No." Thomas James also was injured, and another, Gillmore, had his arm burnt and his hair singed. We landed those men at St. Ives. I have been in a great many ships laden with coal. The gas accumulated in the hold was cause of the explosion Never heard the sailors complain of the hatches being battened down; I did not complain to the mate. The carpenter told me he was going to batten all down for the night, and I told him not to be foolish. Thomas Dunn never spoke to me about it.

(*By Mr. Vachell.*) Going down the river the middle hatch was battened down. The main hold has two hatchways, a small one and a big one; both were battened down. I cannot say whether the after hatch was battened down. On the morning of the explosion the hatchway of the forehold was battened down. The night before the explosion it was blowing a fresh breeze at 12, but it calmed away before morning. We had shipped a great deal of water in the after-part of the ship during the night. When shipping water it is usual to batten down the hatches. I do not consider there was much sea on; there was pretty heavy roll, but the forehatch could have been opened very well.

(*By Captain Castle.*) The height of the covering of the forehatch was about a foot or a foot and a half, and the deck would have to be half full of water before it ran down the hatch. The night before the explosion the sea would open where they put out ashes. When I went below the day before I observed no smell of gas.

(*By Captain Pryce.*) I came on deck on Thursday morning at 8. She would have borne her fore hatches off at that time.

The "Miranda" adjourned Inquiry.
Town Hall, Cardiff, 14th September 1875.

JULIUS SCHALYE.

I am second mate of the "Miranda." I joined her two years ago in London. I have been six or seven voyages in her. She had coal on board every voyage. We arrived in Newport in August. I was on board while she was loaded. The holds were all swept and clean before she began taking in cargo. She was three or four days taking in cargo. During the time there were some showers. I was on board when the coals were put in forehold; they were not wet. There were some showers. Finished loading the day before we sailed (Tuesday). On the 25th we got out of the dock about 12. We were about a couple of hours going down the river. The after hatch was open when we left dock. It was battened before dark; the middle hatch was battened down about the same time. The fore hatch was closed about 7 o'clock. I was on the bridge at that time. The decks were cleaned up during the afternoon, about 2 o'clock. I did not notice the boatswain coiling up rope on the middle hatch. We had a strong breeze on getting into the channel and it continued during the night. During my watch, from 4 to 8, there was less wind, but the same sea. I came on deck at 12 at noon on the Thursday; as I came down the explosion took place, but I had time to notice that the small hatch of the main hold was open. I did not notice whether the after hatch was open. At 6 o'clock on the morning of Thursday I gave orders to one of the A.B., John Hansen, to go down the forepeak and take out some paint scrubbers. I told him, "Don't take any light with you." The forepeak is a dark place. I watched him from the bridge. I could see into the forecastle. He did not take a light with him. There was no light in the forecastle. I saw none during my watch. When the explosion took place I had just come down the foredeck to my berth. When the explosion took place I saw a lot of flame and smoke come out of the forehold. We went to get the lifeboats ready, and then put water down the forehold, because the coal was on fire. There was a lamp in the forecastle, hanging up. It was lit at 8 in the evening, when the sailors turned in. I do not know whether there was a Davy lamp on board. While going down channel I never heard any complaint from the crew about the hatches being battened down. I think the accident was the consequence of naked lights.

Cross-examined.

It was prudent to batten down the hatches on that night, because we shipped any amount of water over the bows. The crew could not keep a watch on the forecastle. On the morning of the explosion I went below at 8. It would not have been prudent at that time to take the hatch off, because there was a heavy head sea. I know the scuttle into the forepeak. It was similar to those I have seen in other vessels. I have never seen a padlock to any such hatchway. The mode of ventilation on this voyage was similar to that adopted on previous voyages. The carpenter had been two voyages in the vessel before this. I have been on board two or three steamers before. None of them had been ventilated otherwise than by the hatches. It would have been possible to have coiled rope on the main hatch if one or two of the hatches had been open. I am sure the main hatch was open while we were going down the river.

(*By Captain Castle.*) There was any amount of water over the bow after daylight. The forecastle was lighted during the day from the companion and bulls' eyes in the sides. I have never seen ships fitted with iron bits ventilators.

(*By Captain Pryce.*) The chain cables were bent to the anchor. The pipe to the locker was covered.

EDMUND SQUIRE ROBERTS.

I am agent at Cardiff for the Peninsular and Oriental Company, and have been here since 1870. We ship about 100,000 tons a year. Always endeavour to get the best description of coal, what is called the Cardiff steam coal. We ship a good deal of Powell's Duffryn steam coal. In shipping the best Cardiff steam coal only the usual precautions are necessary, that is, to keep a free current of air through the ship. There are other modes used, but I think them prejudicial. A great many vessels have large wooden ventilators coming through the deck. They are to prevent combustion. If coals are shipped dry we do not expect combustion at all. The coals from the pits named are likely to generate gas quickly. Gas would be generated in the hold of a vessel from such coal in a very few hours, particularly if shipped in wet weather. Coming fresh from the colliery, and put at once on board, it would be more liable to generate gas more quickly. Having on board such a cargo a master should then have his hatches open as long as weather would permit; he certainly should not batten them down for 24 or 36 hours after taking in the cargo, if it be possible.

(*By Mr. Vachell.*) There are times when the hatches must be battened down. It is very important to keep the coal dry. I have seen a great many steamers here loading with coal; none that I have seen have had ventilators; nothing but the hatches, and cowls at either end of the vessel. I am speaking from what I have seen and from what I have to do with. I have heard of explosions in the dock.

Re-examined.

It is absolutely necessary that a ship should be fitted with the cowls I speak of. If I did not see them in the vessel I have to do with, I should certainly speak about it.

(*By Captain Castle.*) It is necessary to have a free current of air in a ship built in compartments, I should think it necessary to have ventilation in each compartment.

(*By Captain Pryce.*) I should think it imprudent to fill each compartment with this kind of coal, and to cover up the hatches for 24 hours without some means of ventilation. And it would be madness to take a naked light after the hatches had been down for 17 or 18 hours near any orifice by which the gas might escape. I do not approve of loading the coal right up to the deck. The diameter of the pipe of the ventilation of the ship I have had to do with would be 14 inches, but smaller pipes would do. A gas pipe of 3 inches would carry away a great deal of gas. I have seen a chain pipe used as a ventilator. I have seen bits used as ventilators.

MOSES SHORES.

I am chief engineer of the "Miranda." I have been over three years in her, and during that time she has been engaged in carrying coal. On Wednesday, 25th August last, we were in Newport. I was very busy with the machinery below. I did not notice when they finished putting in the cargo. We passed Cardiff about 4. I came on deck while they were sweeping the deck. I did not notice the hatches; they were open while we were in dock. On Thursday my watch below commenced at 8. We were going about six knots full speed. We had head winds and sea which began the night before I went off watch at 12 at night. It was blowing and raining then. It got a little finer towards the morning. At 12 on Thursday, when the explosion took place, I was in the engine-room. I was on deck shortly before. I felt a terrific shock, and in a few seconds I had the order to stop her. I did stop her. I went on deck. I saw the captain after the explosion. I saw the carpenter and dressed his wounds. The captain was standing by. I said, "Carpenter, where did you place the light." He said, "I placed it on the seat locker till I lifted the hatch, and the moment I lifted the hatch, the explosion took place and blew me up;" that was all he said. He said to me, I afterwards found the bottom and lid of the lamp. It was the lamp used in the forecastle. I found it under the forecastle amongst the wreck; it was a common oil lamp.

(*By Mr. Vachell.*) There is a safety lamp on board. It was the carpenter's third voyage. I do not know whether he was warned about carrying a naked light. But he asked me on another voyage why he had to take the hatches off, and I explained to him about the gas, and he seemed quite satisfied.

(*By Mr. Castle.*) When I went forward I found the ship damaged; the beams, nine of them, were broke away, the forecastle blown up, the berth all blown to pieces, the forecastle bulkheads blown out, the main deck blown up right away to the foremast, and the sheer plate bulged out.

The bulkheads blown in so far as the mainhold, the mainsail split from the rigging right on the forecastle; the front of the deck and the poop is broke; the deck ends on the poop are broken; the stringer plates were started. I missed Davies about half an hour after the explosion. The second mate was, I believe, sent down the forepeak to look for him. I do not know whether a boat was lowered, or whether anyone was sent aloft to look out for the body.

JOHN HANSEN.

I am A.B., lately of the "Marinda." On Wednesday, 25th of August, she completed loading. I was then on board. We left dock about 12; the hatches were all open. They were fastened down at 8 o'clock that night. There was a head wind and strong breeze, and we shipped a deal of water that night. On the Thursday morning I relieved the wheel at 12 o'clock. At 6 o'clock that morning I went, by order of the second mate down the forepeak, for paint scrubbers. He said "You don't want a light." I said I did not want a light because I had put the scrubbers there myself. I did not notice any smell of gas. When I came up I put down the hatch. There was no light when I put it down. I put out the light myself at 4 o'clock; it was an oil lamp, and kept just by the forecastle door. It was a tin plant with a spout. At 12 I went to the wheel, and had been there from 5 to 10 minutes before the explosion took place. I saw smoke and flame and pieces of wood blown about in all directions. Davies was in or near the forecastle. I found a piece of his cap on the deck. When I took the wheel I saw the carpenter working at the bell on the middle hatch.

(*By Mr. Vachell.*) A dinner time it was fine, but a heavy swell from the N.W. At 8 o'clock, I could not say whether it would have been prudent to open the hatches. At 8 o'clock there was a deal of spray to windward. There was a safety lamp on board kept in the store room. I never used it, but I have seen it used. I do not know of an order that it should be used by anyone that went below.

(*By Captain Castle.*) The wheel was right aft on the poop after the explosion. I ran to the bridge to the boats. I expected to go down directly. I saw nothing floating on the water.

THOMAS FOSTER BROWN.

I am a mining and civil engineer at Cardiff. I am acquainted with the coal raised by the Powell Duffryn Coal Company. Freshly worked coal from their colleries put into the hold of a vessel would, if barometrical pressure were lowered, have a tendency to give off carburetted hydrogen gas. It would only be a reasonable precaution to ventilate the hold of a vessel in which such coal is stowed. The hold of a vessel in which a vacuum was left would be more liable to combustion than where the coal is filled up to the deck.

EVIDENCE given on behalf of the OWNERS and MASTER.

JAMES STYLES.

I was for a long time a master mariner and am now a ship agent. I have commanded three steamers carrying coal cargoes, and since I have been agent at Cardiff. I have seen many more. The holds are usually ventilated by the hatchways being left off. In some cases assisted by small ventilators. I do not know of a number of vessels coming to Cardiff that have no ventilators. I have commanded one that had none. There are times in this channel when it is necessary to close the hatches shortly after leaving port.

(*By Mr. Waldron.*) I should think it negligent if I did not see to the proper ventilation of my cargo. It would be partly my duty as master.

(*By Captain Castle.*) The two vessels I commanded had for ventilators upright tubes in iron about 6 inches bore. Plain tubes, without cowls, and about 4 feet from the deck. I recollect, however, having some with cowls and some without. We had one only in each compartment. It was put there to liberate something rather than to create a current. But I agree that there ought to be one at each end. If there had been one at each end we should have kept the cowls on. I imagine the tubes would be better larger than 3 inches. The ship that had no ventilators I had no trouble with, but I felt uneasy sometimes.

(*By Mr. Jones.*) If I had left port, say, at 12 o'clock today, and the hatches remained closed from 6 or 7 this evening until 12 the next day, I should have felt uneasy; but I should have gone on as the captain in this case seems to have done.

HENRY CLOAKE.

I am agent for Messrs. Spire, steamship owners, and was formerly a master mariner, and I have had considerable experience as to vessels coming to Cardiff. I have known many ships coming here for coals which have not been fitted with ventilators. There is a steamer now in dock recently built which is not fitted with ventilators. I have never put a steamer about when she was going against a hard wind because of gas, or heard of its having been done.

(*By Mr. Waldron.*) It is decidedly necessary to have some means of ventilation over the cargo, and I should think wise to take such precautions. I should think I was, to some extent, responsible for the safety of my crew. If a ship is going head to wind gas would get to the fore part of the ship.

(*By the Court.*) If I had had coal battened down for 17 hours I should have endeavoured to prevent lights being used.

Report of the Court.

The "Miranda" was an iron screw steamer belonging to Hull, official number 60,140. She was built at Stockton-on-Tees in 1868, her registered tonnage 865·73 tons, and she was owned by E. Leetham and others, at Hull.

She left Newport about noon on the 25th August, with a full cargo of 1,579 tons of smokeless steam coals, bound to Kiel, and had a crew of 23 hands, all told, including the master, Mr. Wilhelm S. A. Van Deurs, who holds a certificate of competency as master, No. 18,491.

After clearing the Newport River she met with strong south-westerly winds and a considerable sea, which caused her to ship some water, but not sufficient to necessitate the hatches being put on.

All proceeded well until about 6.30 p.m., when, as the wind was increasing and night coming on, the whole of the hatches were put on and battened down that time, until after daylight the following morning, the wind continued fresh, with a high sea, and the vessel shipped such large quantities of water that the look-out man on the forecastle had to be removed to the bridge.

After 6 a.m. the weather moderated, but the sea still continued so high that it prevented the hatches being taken off, without the risk of wetting the cargo. Nothing further of importance occurred until shortly after 12 p.m. The forenoon watch had just been relieved, and the first officer and the master were on the bridge, when about 12.15 a terrible explosion took place in the fore-part of the vessel, which was instantly enveloped in smoke and flame. The engines were at once stopped and boats got ready for lowering; meanwhile it was noticed that the whole of the fore-part of the vessel, from the foremost forward, had been blown up by the explosion. As some fire was seen, the donkey engine with hose was at once set to work, and in about twenty minutes the fire was extinguished.

The extent of damage is described as follows:

Nine beams broken.
Forecastle deck and all the butts blown to pieces.
Main-deck blown up as far aft as the foremast.
Iron bulkhead to main-hold bent aft some four or five inches.
Stringer plates on both sides lifted.
Main-rail split, and sheer-strake, and bulwarks much disturbed.

The well was sounded, but the vessel made no water.

On mustering the crew it was found that Benjamin Davies, one of the crew, was missing, and is supposed to have been blown overboard, as portions of his clothing were found in the rigging.

The carpenter was most seriously burnt, and Thomas James, seaman, was also hurt. These two men were landed at St. Ives to receive medical help, about two hours after the accident, and were left in the infirmary there.

The "Miranda" then bore up for Cardiff.

The Court, on the evidence given before them, attached no blame whatever to the master, and they therefore returned him his certificate.

They find that this casualty is clearly to be attributed to an explosion of gas, caused by the use of a naked light near the scuttle of the forepeak by the carpenter, previous to and when he opened the scuttle, the gas having found its way from the hold through the collision bulkhead.

The gas had accumulated in the fore-hold from the time the hatches were battened down on the evening of the 25th until the explosion took place, and had no means of exit.

It was stated in evidence that the whole of the cargo consisted of freshly wrought coal, none, with perhaps the exception of a few waggons, having been above ground more than twenty-four hours. In this state it was more dangerous than it would have been if exposed longer to the atmosphere.

After the loading was completed on the evening of the 24th August, the hatches were left off all that night until 6.30 p.m. on Wednesday evening, when they were battened down. From that time till the explosion, a period of 17 hours, the gas had been accumulating in the holds, which had no ventilation whatever.

After hearing competent and experienced mining engineers and other experts on the subject, the Court feel it their duty to offer some suggestions for future guidance with regard to these dangerous cargoes, and therefore respectfully ask the attention of the Board of Trade to the following points :

1. That all vessels about to carry cargoes of gaseous coal should be fitted with ventilating pipes or shafts at each end of either compartment or hold, that is, that there should be two ventilators in each hold or compartment, so fitted as to be constantly kept open.

2. That it is advisable in carrying this description of coal to have a small space between the deck and cargo, so as to insure a free circulation of air between the ventilators.

3. That the master should be instructed to have the hatches off whenever practicable during the voyage.

4. That naked lights be strictly prohibited.

Dated this 15th day of September 1875.
(Signed) R. O. Jones,
Stipendiary Magistrate.

We concur in the above Report,
(Signed) John S. Castle, } Nautical Assessors.
Chas. E. Pryce, }

In addition to these, the following Cases of Explosion of Gas in Coal-laden Vessels, in which no Statutory Inquiry was held by the Board of Trade, have also been reported by that Department to the Commissioners :—

"THOMAS PARKER," of Sunderland, an iron steamship of 739 tons register, four years old, and classed A1 Lloyds.

Was lying in South Dock, Sunderland, and bound for Cronstadt with 1,350 tons of gas coals; the hatches were left off, and also a hatch in store room, for ventilation.

On the 9th September 1875, about 9 a.m., four coal trimmers went into the after hold, each taking an unlighted candle, when one of them struck a match to light the candles and an explosion immediately followed. The flames reached nearly up to the mixed cross trees, but the fire went out shortly after the explosion. One of the crew was slightly burnt, and four coal trimmers burnt, one very seriously. The damage done altogether to ship and cargo amounted to about 85*l.*

"LOUISA THERESA," of Vannes, France, a wooden ship of 200 tons register, 20 years old, and classed 3/3–1–1, French Veritas.

Sailed from Cardiff for Mataro with a cargo of coals on the 16th January 1876, and on the same date, when in the Penarth Roads, an explosion of gas took place on board, owing, it is believed, by the gas coming up through the hatch in the Lazarette and igniting by the fire in the master's cabin.

"ATALANTA," of Greenock, O.N. 67914.

The Board of Trade forwarded to the Commission the following report, with its enclosure, from one of the Board of Trade's surveyors at Cardiff, relative to the explosion of coal gas on board the "Atalanta :"—

Board of Trade.
Cardiff, June 22nd 1876.

Explosion of Coal Gas on board ship "Atalanta" of Greenock, O.N. 67914.

In forwarding the account of above-mentioned catastrophe, I respectfully beg to suggest for the consideration of the Board the advisability of making it compulsory for *all* vessels to have a ventilator forward and aft, as it is at the *ends* of the vessel that gas always accumulates. There have been six or seven explosions of coal gas on board vessels here since I have been stationed at this port, and in every instance the explosion has been either at the forward or after end of vessel.

More elaborate means of ventilation may be suggested, but the use of an ordinary iron cowl ventilator at each end of vessel would, I think, be both efficient and simple, and would keep the space at ends of vessels clear even if the hatches should be accidentally closed, thus preventing much loss of life and property by such explosions as this.

Of course this plan is for sailing vessels only. Steamers would require a ventilator in each compartment.

(Signed) W. H. Neate,
Prin. Off. S. Wales.

The Asst. Secretary,
Marine Department,
Board of Trade.

Extract from "Western Mail" of the 20th of June 1876.

Terrible explosion at Penarth. A ship shattered. Four seamen killed and many injured. Marvellous escape of a rigger.

The most disastrous explosion that ever occurred on board a ship at Cardiff took place at 9 o'clock on Monday morning. The inhabitants of Penarth and the Bute Docks were thrown into the utmost consternation at the intense force and report made by the explosion. So great was the shock that many believed an earthquake had shaken the foundations of their dwellings. Persons, however, about the dock at Penarth and on Cardiff pier-head observed the flames and smoke issuing from on board a large ship lying in Penarth Dock, to the height of at least 200 feet, and on hastening to the scene found that a frightful explosion caused by an accumulation of gas from the cargo of coal had taken place on board the barque "Atalanta" of Greenock. The decks were blown up fore and aft from stem to stern, the rigging, sails, and spars broken and enveloped in a black and dense smoke. Immediate efforts were made to get on shore the injured members of the crew.

The "Atalanta," being outward bound and ready for sea, had most of her crew on board.

She completed loading on Friday last, having shipped 1,600 tons of the Glamorgan Coal Company's large steam coal.

The ship was so much damaged that fears were felt lest any of the crew could survive the accident, but the exploring party nobly pursued their labours, descending into the ship's hold, cabins, and forecastle, in search of the dead and dying. Men were found shockingly burnt about the head, arms, and body. These were speedily landed, and placed in the store of Mr. Clode, butcher, who kindly lent his premises on Penarth Wharf for the use of the wounded. Dr. Nell was soon in attendance, and ordered some of the cases to be removed without delay to the "Hamadryad," hospital ship. Three cases, however, he retained, viz., that of Matteo, an Austrian seaman, Donald McKerrel the carpenter, and Captain William Brown. The Austrian succumbed to the injuries he had received at 10.30 a.m., his body being removed to the Penarth mortuary. The carpenter was subsequently forwarded to the hospital ship very badly hurt, and Captain Brown, who also was much burnt about the arms and head, was conveyed to a private residence at Penarth.

While the wounded were being thus attended to, and that in a most efficient manner by Dr. Nell, it was discovered that Mr. Whitworth, chief officer of the "Atalanta," had been killed; also an ordinary seaman, named John Hamett. Both bodies were carried to the mortuary.

At a short distance from Mr. Clode's store another crowd was assembled around one of the dock lodges, wherein was found the mate of another ship, the "Killochan," of Greenock, most dangerously wounded. He was in the act of shaking hands with Mr. Whitworth, of the "Atalanta," on that ship's deck when the explosion occurred. Mr. Whitworth was killed, and Mr. Alexander Muir, mate of the "Killochan," was thrown about 40 feet into the air. In alighting, his head came in contact with a spar, contusing the skull. His right leg was at the same time broken. He lies, as stated, in a hopless condition.

As to the cause of this direful event, it has been clearly ascertained to have arisen from the accumulated gas from the cargo being ignited by a match lit by one of the seamen, named Antonio Pedro. He accompanied H. Ross, second officer of the "Atalanta," into the after hold. Mr. Ross carried a naked candle, and no sooner had Pedro struck the match to light the candle, than the explosion took place. Both of these men, who are badly burnt, are lying at the hospital ship.

The "Atalanta" is a ship of 1,116 tons register; built at Richmond, United States, in the year 1857. She is the property of Mr. C. S. Caird, of Greenock, and was bound from Cardiff to Hong Kong. Strange to state, the ship that was alongside of the "Atalanta" at the time, viz., the "Killochan," likewise belonged to Greenock.

APPENDIX III.

ADMIRALTY CASES.

THE following Papers have been received from the ADMIRALTY relating to cases of SPONTANEOUS COMBUSTION or of EXPLOSION in the COAL BUNKERS of HER MAJESTY'S SHIPS, and in certain of the GOVERNMENT COAL STORES.

H.M.S. "EUPHRATES."

(Spontaneous combustion in starboard coal-box.)

The following is an extract from the report of the captain of the "Euphrates," of the spontaneous combustion which occurred in the coal-box of that ship on the 9th April 1868.

H.M.S. "Euphrates,"
Bombay, 10th April 1868.

SIR,

I HAVE to report for your information that an occurrence happened last night on board H.M. Ship under my command which might have been attended with very serious results, but for the watchfulness of the engineers on duty in the engine room at the time, and the measures which were adopted on my being informed of it.

The circumstances are as follows:—We had sighted Kolarba and Kautari Lights about 9 p.m., and had stopped the engines so as to wait till daylight this morning for coming into harbour to our moorings. Shortly before midnight the chief engineer (Mr. Eyers), reported to me that smoke was observed to be issuing from the starboard coal boxes, and he had no doubt that spontaneous combustion had taken place:—Fortunately there were only about 20 tons of coal in that particular portion of the bunkers. A hose from the donkey engine, and also from the foremost pump on starboard side of main deck, were immediately led into the coal box in question, and very shortly the place was flooded; and whatever combustion there was about the coals were completely put out. * * * *

In conclusion I beg to inform you of the cause of the combustion, viz., that Spencer's patent cement round the boilers is not properly secured, in fact is not secured at all; and from the great heat has got so dried up that it has fallen off, consequently leaving nothing between the great heat of the boilers and the coals behind them. I would therefore suggest that some means (iron bands or otherwise) may be adopted for boilers coated with the same composition for the purpose of keeping it from falling off.

I have, &c.,
MONTAGU B. DUNN.

H.M.S. "MINOTAUR."

The following is an extract of the Report received at the Admiralty of an explosion of gas which took place in the coal bunkers of H.M.S. "Minotaur" on the 25th June 1869:—

"On the 25th instant, while taking in shell, an alarm of fire was reported in the compartment in which the shell are stowed.

"The ship's company proceeded to their stations, and it was immediately ascertained that a slight explosion of gas had taken place at the starboard after coal bunker, opening into that compartment. The bunker has two manholes in the compartment, and three shoots from the maindeck.

"The temperature had been taken at midnight and showed 78° at the foremost and 68° at the after end, which were the same as on arrival at Spithead after steaming.

"A leading stoker had been sent to examine the boxes and had opened a manhole in the compartment. As he lowered his light it was extinguished by a rush of gas, and he, as well as the gunner's mate at the shell-room hatch, believe that they saw a slight explosion. An A.B., who was sitting on the lid of a shoot on the main deck, felt the lid move under him. He got off and it was lifted six inches, and he also believes that he saw flame.

"The rush of gas brought with it a good deal of coal dust, and there was for a moment an impression amongst the men working at the shell whips, that a fuse had ignited.

"The bunker was cleared and the coal transferred to other places, but no trace of fire could be discovered among them, or anything which would appear to give rise to fire damp. They appeared dry and in good order."

The Inspector of Machinery on being called on for his opinion as to the cause of the explosion, reported as follows:—

I have the honour to report that in my opinion the explosion alluded to as having occurred on board H.M.S. "Minotaur" on the 25th inst. was caused by an accumulation of gas (carburetted hydrogen) being pent up in the coal bunkers, and having no means of escape by which, on being released by the stoker with the light, on his removing the cover caused it probably to ignite. This gas is constantly being generated and evolved more or less with all kinds of coal, but accidents are usually guarded against by having the bunker covers removed daily for a few hours, when the gas passes off and mixes with the atmosphere in such small quantities as to be imperceptibly felt; but as the covers are mostly in the cable tier in this ship, it would not be safe to remove them daily to allow the gas to escape; therefore means should be adopted to carry it at once into the atmosphere.

I would suggest in vessels of this class, where large quantities of coal are stowed (remaining as it does a long time in the ship), to have a ventilating pipe fitted from the coal bunkers leading to an outlet on the upper deck where the gas might freely escape; this, together with removing the coal bunker covers daily when in harbour, would prevent a recurrence of such an accident (when at sea under steam, the furnaces will keep the coal bunkers clear of gas).

I beg most respectfully to bring to your notice the evil of allowing water to pass into the bunkers, whilst washing decks before time has been given to replace the covers after coaling ship. This practice is very dangerous, more especially with Newcastle coal, as moisture causes heat and gas to be evolved very rapidly, and in this kind of coal, where iron pyrites are present in considerable quantities, the danger is all the greater (it does not however always follow that the temperature is increased when the gas is given off).

The Admiralty then issued the following circular to the Fleet, inclosing the extract quoted above from the report of the explosion on board the "Minotaur."

(Precautions against accumulation of gas in coal bunkers.)

Circular No. 44. Admiralty,
July 29th, 1869.

The accompanying report having been received from the "Minotaur" of an explosion of gas having taken place in the starboard after coal bunker of that ship, on a light being lowered through one of the man holes, the attention of all officers commanding Her Majesty's ships is called to the necessity of opening the lids of coal bunkers occasionally so as to allow of the escape of foul air, and prevent the accumulation of gas, which is constantly being evolved, more or less, as regards all descriptions of coal.

Care should be taken to prevent water passing into the bunkers whilst washing decks, before time has been given to replace the covers after coaling, such practice being very dangerous, especially with Newcastle coal, as moisture sometimes causes the rapid generation of heat and gas.

By command of the Lordships,
VERNON LUSHINGTON.

To all Commanders-in-Chief, Captains,
Commanders, and Commanding Officers
of Her Majesty's ships and vessels.

H.M.S. "MEGÆRA."

(Heating of coal in the bunkers.)

The following is an extract from a letter dated 7th January 1870, reporting the proceedings of H.M.S. "Megæra":—

On December 26th the coal in the starboard wing bunker was found to be heated, temperature 130°, which I ordered to be used at once; but the temperature still increasing to 145°, I deemed it advisable for the safety of the ship to clear the bunker, which was done by getting up and starting the coal on the main deck, and also by increasing the revolutions of the engines and the expenditure of coal. A moderate breeze from the southward having sprung up on the 27th December, the ship had been placed under sail and the fires burned down, but as the coal in the port bunker also began to heat temperature 130° to 132°, I gave directions for the steam to be got up again, so that the coal might be used and the heated place arrived at, as from the quantity of cargo stowed on the main deck as well as the coal already got up, there was no more space for stowage there.

The wing bunkers are now quite clear of coal, and the temperature of all the bunkers has assumed its normal condition.

Commodore Dowell, with a view to ascertain the cause of the high temperature of the bunkers, ordered an inquiry, of which the following is the report:

H.M.S. "Megæra," Ascension,
January 11th, 1870.

SIR,

IN compliance to your memo. of this date we came on board this ship to inspect the bunkers and endeavour to ascertain the cause of their dangerously high temperature, and have now the honour to inform you that we are of opinion that the temperature 145° while steaming and that immediately behind the boilers is not a dangerous one, but it being a sudden rise from that of the usual temperature, viz., 90° had been we are of opinion that the removal of the coal from that part was advisable.

Every proper precaution to prevent undue heating by opening the lids, &c., appears to have been taken.

The bunkers appear to have sufficient ventilation, and we do not see that any alteration or improvement can be made.

We cannot attribute the increased and sudden rise in the temperature of the coal to any other cause than its nature (Hirwain's Diamond Coal) which is of a softer texture and appears to emit gases more freely than the other, viz., North Country, as the different temperature in similar heated parts of the bunkers where these coals were stowed were Hirwains 146° and North Country 90°.

We have, &c.
(Signed) J. BURGESS,
Commander H.M.S. "Pandora."
A. MILLS,
Chief Engineer H.M.S. "Rattlesnake."
J. DALTON,
Engineer H.M.S. "Pandora."
H. M. SMALL,
Engineer H.M.S. "Rattlesnake."

The Commodore forwarded these reports to the Admiralty with the following letter.

"Rattlesnake" at Cape Palmas,
February 18th, 1870.

SIR,

THE officer commanding the "Megæra" having represented to me that on his passage from England to Ascension, the coal in the bunkers became excessively heated, and that he had deemed it necessary for the safety of the ship to clear the two wing bunkers, I ordered an inquiry into the particulars of the circumstances with a view to ascertain the cause of the high temperature of the bunkers, and whether anything could be done to prevent it again happening.

The report of the inquiring officers is forwarded herewith, and it would appear that although the rise in the temperature of the bunkers was sudden, and sufficient to create some anxiety, it never reached a dangerous pitch. The bunkers are reported to be well ventilated, and precautions were taken to prevent any undue heating.

If the statement made to the inquiring officers in reference to the excessive heat generated in the bunkers from Hirwain diamond coal is correct, it would appear that that description of coal is not fit for the service; but their Lordships are doubtless in possession of information from other sources which will enable them to form a correct opinion as to the qualities of the kind of coal supplied to the "Megæra."

I have, &c.
W. M. DOWELL, Commodore.

On receipt of these reports the Admiralty called for a report from Sheerness of the particulars of the coal supplied to the "Megæra," from whom they were received, &c.

The following are copies of this report and its inclosures:

Sheerness Yard,
April 4th, 1870.

SIR,

WITH reference to your minute on Superintendent of Stores, Order N.S. $\frac{2108}{2769}$, of the 1st instant, directing us to report the particulars of the Hirwain Welsh coals supplied to the "Megæra" on the 12th October last, from whom they were received, &c., we have the honour to report that these coals were received from the Hirwain Coal Company under agreement of 5th, and Superintendent of Contract's letter of 15th May last, observing the coals are not called Diamond, that being the name of the ship from which they were delivered.

The cargo was carefully inspected prior to breaking bulk in accordance with Admiralty Order S.T. of the 28th April last, and the following report inserted on invoice of receipt, viz.:—

28th July 1869. The coals, Welsh S.V. have been surveyed in accordance with the instructions, and there is nothing in their appearance to prevent immediate delivery.

In addition to which, the cargo was examined during delivery and found to consist of the same quality of coals as seen on first inspection.

During the delivery of the coals a trial of their evaporative power was made on board the steam-tug "Otter" attached to this port, and the result reported in officer's letter of the 4th August 1869, a copy of which is forwarded herewith.

Subsequent trials of this coal mixed with North country coals were made at the coal testing boiler in this yard in accordance with Mr. McCulloch's wishes. See officer's letter of the 12th August 1869, copy herewith.

Their condition when issued to the "Megæra" was the same as at the time of their receipt.

We have, &c.
R. COBBETT, Storekeeper.
A, B. STURDEE, Master Shipwright.

Sheerness Yard,
August 4th, 1869.

SIR,

WITH reference to your memorandum on Superintendent of Contracts, Order 1591, of the 19th ultimo, directing the officers to make a very detailed and particular report as to the quality of the Hirwain coals lately delivered at this yard, under purchases made by Mr. McCulloch. We have the honour to report that a cargo of the Hirwain coals has arrived at this yard, and upon making the usual trial at the coal-testing boiler in the course of its delivery, it was found that the rate of evaporation in cubic feet per hour was very much below the average, and the quantity of refuse produced excessive, it was therefore deemed expedient to make a further trial in the boiler of one of the harbour vessels attached to this port, and in conformity with your directions this trial has been made on board the "Otter."

We find under these circumstances the rate of evaporation extremely low, the fires burning very sluggishly, requiring the constant use of the pricker to produce even the rate of evaporation obtained, and the quantity of cinder and refuse proportionately large.

A trial with Nixon's Navigation coals in the same boiler has been made for special comparison, and the results show the Hirwain coals to be of very inferior quality, unfit for the service, and subject to the rejection provided for by the letter of 6th May last, from the Hirwain Coal and Iron Company to the Admiralty.

The coal per "Diamond" has been rejected accordingly on the invoice.

A tabular statement of the result of the trials of the Hirwain and Nixon's Navigation coals for comparison is forwarded herewith.

(Signed) A. B. STURDEE, Master Shipwright.
J. BANNISTER, Engineer.

(Copy.)

SHEERNESS YARD, 4th August 1869.

Description of Coal.	Name of Vessel.	Date of Trial.	Pounds of water evaporated per lb. of coal consumed.		Cubic feet of water evaporated per hour.		Percentage of			Smoke.	Remarks.
			Calculated at the temperature of the feed.	Calculated at 100° constant temperature of the feed.	Calculated at the temperature of the feed.	Calculated at 100° constant temperature of the feed.	Ashes.	Clinkers.	Both ashes and clinkers.		
Hirwain coals -	"Diamond"	1869 2nd Aug.	6·273	6·432	34·40	35·27	34·87	·73	35·60	Very light.	Fires burnt very sluggishly, although every effort was made to facilitate the combustion of the fuel. The number of cubic feet of water evaporated per hour per foot of fire grate was only 1·07.
Nixon's navigation coals.	From store	3rd Aug.	8·295	8·513	81·66	83·81	8·00	1·02	9·02	Very light.	Fires burnt briskly, ordinary firing. The number of cubic feet of water evaporated per foot of fire grate per hour, 2·15.

Note.—These trials were made in an ordinary marine boiler; area of fire-grate 33·3 feet.

(Signed) A. B. STURDEE, Master Shipwright.
J. BANNISTER, Engineer.

The Captain Superintendent.

Sheerness Yard,
August 12th, 1869.

SIR,

WITH reference to our letter and report of the 4th instant on the quality of the Hirwain coal, lately delivered at this yard under purchases by Mr. McCulloch in which we stated that the rate of evaporation was extremely low and the amount of refuse excessive.

We have the honour to report that in obedience to your directions of Monday last, when Mr. McCulloch visited the yard with reference to the above report, we have made further trials in the boiler used for testing coals at this yard of the Hirwain coal mixed with North Country, the result, as will be seen by the annexed report, shows a much greater rate of evaporation and a reduced amount of refuse.

We are of opinion that this coal may be used mixed with bituminous coal, although it is not adapted for burning in ordinary furnaces (without blast) in its unmixed state.

(Signed) A. B. STURDEE, Master Shipwright.
J. BANNISTER, Engineer.

The Captain Superintendent.

Subsequently the Admiralty wrote the following letter, directing the Superintendent of H.M. Dockyard at Malta to call upon the commanding officer of the "Megæra" to state whether any steam pipe passed through the bunkers in question:—

Admiralty, S. 88.
June 18th, 1870.

SIR,

I AM commanded by my Lords Commissioners of the Admiralty to request you to call upon the commanding officer of H.M.S. "Megæra," to state with reference to the report of the excessive heating of Hirwain coals in the bunkers on board that vessel, contained in his letter of proceeding of the 21st March last, whether a steam pipe passed through the bunkers in question.

I am, &c.
(Signed) T. WOLLEY.

The Admiral Superintendent,
H.M. Dockyard, Malta.

To this letter the Admiral Superintendent at Malta forwarded the following reply from the officer in command of H.M.S. "Megæra," from which it is clear that no steam pipe passed through the bunkers of that ship.

H.M.S. "Megæra," Malta,
July 4th, 1870.

SIR,

IN compliance with directions from my Lords Commissioners of the Admiralty contained in your memo. of this day's date, relative to the excessive heating of Hirwain coal, as reported in my letter of proceedings of 21st of March last, I beg to inform you that no steam pipes pass through the bunkers of this ship.

I have, &c.
H. D. SARRATT,
Staff Commander in Command.

Rear-Admiral A. C. Key, C.B.,
Admiral Superintendent.

H.M.S. "MALABAR."

(Spontaneons combustion in coal bunkers.)

The following is the report of the captain of H.M.S. "Malabar," of the fire which occurred in her coal bunkers on 24th February 1872.

H.M.S. "Malabar,"
Bombay, 2nd March 1872.

SIR,

I BEG to report that on the morning of the 24th February the coal in the bunkers was discovered to be on fire.

At 4 a.m., a strong smell of sulphur was observed by the men working in the bunkers behind the boilers, on both sides about the same time. These bunkers were immediately closed, and also the watertight doors and all ventilation stopped.

The doors in after end of the stoke-hole were opened, and the coal got out as fast as possible; much of it was found to be smouldering and heated and only requiring a little air to burst into a flame.

When the coal was sufficiently cleared away, a hose was got into the bunkers and water played on the coals: the fire on port side was soon got under, but on the starboard side the fire seemed to have got more hold of the coals, and it was found necessary to flood this box entirely.

I am unable to give any cause for this occurrence; the coal was received at Malta from under cover only 16 days before (on the 8th February), and was perfectly dry and apparently well mixed, half Welsh and half North country.

The test tubes did not show any sign before the discovery and afterwards they never showed more than 111°, which is very little above the usual temperature when in the Red Sea.

Coals were described as—

Cowpen Hartley, received at Malta	-	April '71
And Fothergill's, Aberdare ,,	-	Sept. '71

It is fortunate the state of the coals was discovered so soon as it was, or the consequences might have been serious.

Those engaged worked well and quietly. I did not deem it necessary to stop the ship, and I believe at the present moment most of the officers and troops are unaware of the occurrence. No damage has accrued to the ship.

I have, &c.,
SHOLTO DOUGLAS.

H.M.S. "RATTLESNAKE."

(Spontaneous combustion in coal bunkers.)

The following is the report made by the chief engineer of H.M.S. "Rattlesnake" of the case of spontaneous combustion which occurred in her coal bunkers in February 1872.

H.M.S. "Rattlesnake," at Elmina,
7th April 1872.

SIR,

I HAVE the honour to make the following report on the Cowpen Hartley Coal (142 tons) received on board this ship from the Naval Depôt at Sierra Leone.

At 6 a.m., on the 20th February, smoke was discovered to be issuing from the coal boxes at the back of the starboard boilers.

The coals were removed into the stoke hole until the origin of the fire was discovered on the removal of about 20 tons.

The origin of the fire was to be attributed to spontaneous combustion, as shown by the discoloured appearance of the coal.

Every precaution was taken to ensure its being stowed quite dry in the boxes, and as it was observed to possess a large quantity of sulphur and iron pyrites special care was taken.

There being very little coal on the station, it became necessary to complete from the quantity in store at Sierra Leone, and care was taken that this coal was first consumed.

The coal was also indifferent for generating steam, and on being put into the furnaces, it burnt bright and brisk, but soon become dull and dead, causing extra work to the men from continued firing and pricking, thus showing it to be not only dangerous, but totally unfit for tropical climates.

I have, &c.,
H. W. ELGAR.

This Report was forwarded to the Admiralty by Commodore Commerell with the following memorandum:—

Forwarded for the information of the Lords Commissioners of the Admiralty, observing that I quite concur in the remarks of the Chief Engineer, that this coal was quite unfit for use in a tropical climate.

Fortunately the combustion in the bunkers was discovered in time to prevent any serious disaster and no damage was done.

As a preventitive against a similar occurrence, I have forwarded the particulars of this spontaneous combustion to the Naval Agent at Sierra Leone, for the information of the Officers Commanding H.M. ships coaling there, pointing out that this coal is by no means fit to supply to H.M. ships, and that every precaution is to be taken to prevent danger.

H.M.S. "GLASGOW."

(Spontaneous combustion in coal bunkers.)

The following is a copy of the report of the captain of H.M.S. "Glasgow," of this case of spontaneous combustion, which occurred on 22nd June 1872:—

H.M.S. "Glasgow," at Sea,
25th June 1872.

SIR,

I HAVE the honour to inform you that an alarm of fire was reported to me about 4.15 p.m. of the 22nd instant in the starboard after coal bunker, of H.M. ship, under my command under the following circumstances:—

On Mr. Pearson, the engineer of the 4 to 6 watch passing the bunker door in the stoke hole, he perceived a strong smell of smoke, and on entering the bunker found the smell stronger and smoke arising in considerable quantities, he immediately acquainted the chief engineer, and on its being reported to me the ship's company were assembled at their fire stations, and after a personal inspection of the bunker, where I found much smoke and heat, a considerable quantity of water was pumped into the bunker.

Immediate steps were taken to remove the coal, which was done as fast as possible, the pumps being kept going at the same time.

On removing the coals to the depth of about six feet, the greatest heat appears to have been reached, extending for a space of about four feet athwartships, the temperature shown by thermometer being about 135°, this great heat extending to a considerable depth.

By 11 p.m. the heated coals had all been cleared out, and the bunkers became cool, and on further examination no damage appears to have been done to the wood-work (sheathed with copper) which was in immediate contact with it.

The temperature of the bunkers, tested every four hours during the day, showed 98° the maximum.

I beg to enclose a list of the quantities and description of the coals received on board the ship since arrival at Suez, when the bunkers were empty, and, as far as I can ascertain, the heated coal in the bunker was a mixture of that supplied at Aden, Bombay, and Trincomalee, that of Bombay being the smallest and worse quality; but I am unable to say in what proportions, the total quantity in this compartment being about 82 tons.

The coals were received on board in a perfectly dry state, in tight lighters, the weather very fine and the sea perfectly smooth.

The bunker lids fit close, and no water has ever been discovered to pass through from the deck into the coals.

The door of this bunker in the stoke hole had been open since the last coals were received on board, and there being a run of coals in it for charging fires and culinary purposes, a large space had been consequently for some time free for the escape of gas and heated air.

I am unable to assign any cause for this overheating of the coals other than the result of spontaneous combustion.

I have, &c.,
T. MORTON JONES.

The Admiral Commanding-in-Chief forwarded this report to the Admiralty with the following remarks:—

"I do not believe that the fact of the coal being Welsh had anything to do with this occurrence. The 'Glasgow' called at Bombay immediately after the squadron, then under my command did, and I think it will be found that a large proportion of what she received there was North Country."

HER MAJESTY'S COAL STORES AT JAMAICA.

(Cases of spontaneous combustion.)

The following is a copy of the Report of Survey, dated 29th August 1872, on certain coal stored in H.M.S. Yard at Jamaica, from which it appears that two lots of North country coals (180 tons and 240 tons respectively), shipped to Jamaica in the colliers "Sophia and Jane," and "Mary Ann Johnson," (which arrived there 8th May and 9th July respectively,) were condemned as unserviceable in consequence of spontaneous combustion.

H.M.S. "RACOON," 29th August 1872.

A REPORT of SURVEY held on the following STORES, in HER MAJESTY'S YARD at JAMAICA, in pursuance of an ORDER, dated the 28th August 1872.

—	Species.	Estimated quantity tons.	Condition.	Cause of decay or unserviceableness.	Convertible or not, if the former, to what purpose.	Whether they should be sent to England, or sold in the country.	Remarks.
Lot 1.	Coal - - North Country. Ex "Sophia and Jane." (In store.)	270	Good and serviceable.	—	—	—	It is desirable that ships taking this coal should be informed that spontaneous combustion has occurred in portions of the same cargoes, and that it should be mixed in stowage with two thirds Welsh, as usual.
Lot 3.	Ditto - - Ex "Mary Ann Johnson." (In store.)	261					Ditto.
Lot 2.	Coal - - North Country. Ex "Sophia and Jane." (In the open.)	180	Unserviceable.	Combustion and heat and admixture with sand, &c., which last will inevitably be much increased by removal from its present position.	Not convertible.	Sold in the country.	This coal is of a highly bituminous nature. It has been stored in considerable quantities rather close under a roof of corrugated iron only, the temperature there having been as high as 97° in the day-time, while in the centre part of the store, the roof of which is additionally protected with boarding, it is seldom over 84°. From the quantity of coal in store there was but little ventilation. It may have become heated by getting damp at some time, but there is no evidence of such being the case.
Lot 4.	Ditto - - Ex "Mary Ann Johnson." (In the open.)	240		Ditto.			

The following is a report from the Commodore at Jamaica, of a further case of spontaneous combustion which occurred in the same stores.

"Aboukir," at Jamaica,
September 5th, 1872.

I HAVE the honour to report for the information of the Lords Commissioners of the Admiralty, that a portion of the North country coal contained in No. 1 store was again found to be spontaneously heated on the morning of Sunday the 25th instant, this time on the north side of the store.

2. The coal which heated this time is part of a cargo of "Cowpen Hartley, North Country Steam Coal," which was landed ex "Sophia and Jane," in April of this year.

3. The heated coal was fortunately not in the central store, and could therefore be removed, but for this purpose it was requisite to take down a portion of the wall.

4. It was found necessary to remove about 240 tons of coal which, with the amount which caught fire on the previous occasion, as reported in my letter No. 63 of the 24th ultimo, being reported unfit for issue to Her Majesty's ships will be sold by auction.

5. In case of erecting coal stores in this or similar climates in future, it would be in my opinion desirable to have wood or some non-conducting material underneath the roof sheathing, whatever it may be. The officers who surveyed the heated coal report that whilst the temperature in the upper part of the store roofed with zinc sheets over wood was 84°, in the stores roofed with corrugated zinc without wood underneath it was 97°, and it was in the latter store that in both cases the coal caught fire.

6. I am inclined to think that the last-named cause, together with the inflammable nature of the coal, (for it appears to contain a considerable quantity of sulphur and iron) and the want of ventilation are sufficient to account for the spontaneous combustion.

7. The better ventilation of the coal stores has been in progress since the first fire occurred.

I have, &c.,
A. F. R. DE HORSEY.

On the 7th November 1872 another case of spontaneous combustion in the Jamaica coal stores was reported to the Admiralty. The following is a copy of the report:—

H.M.S. "Aboukir," at Jamaica,
7th November 1872.

SIR,

I HAVE the honour to report that a portion of the coal contained in No. 2 Store was on the 31st ult. found to be in a state of spontaneous combustion.

2. The coal which took fire this time (the third time in three months) is part of a cargo of Cowpen Hartley's North Country Steam Coal which was landed ex "William" in April of this year.

3. It was found necessary to remove about 74 tons, most of which will probably be serviceable.

4. The vicinity of one of the large doorways (which I had lately caused to be made in the walls of the depôt), enabled the heated coal to be removed without difficulty.

5. It will be observed that the coal which heated this time, as on former occasions is North country, the supply of which, received in the spring of this year, appears to have been of an inflammatory description.

I have, &c.,
A. F. R. DE HORSEY.

The following is a memorandum dated 2nd November 1872, drawn up by Mr. Rowsell, Director of Contracts, with special reference to the foregoing cases of spontaneous combustion in H.M. ships and coal stores:—

Several cases of spontaneous combustion having been reported within the last few months, noteably in the "Glasgow" "Rattlesnake" and in the coal store at Jamaica, and varying opinions having been expressed as to the cause, and as to whether Welsh or North Country coal is more liable to spontaneous combustion, it seemed right to ascertain the opinion and experience of the trade upon the subject.

As far as could be done during a hurried visit lately to South Wales and to the North, this has been done, The results are as indicated in the following extracts from notes of conversations at Cardiff and Swansea :—

"No. 1. No spontaneous combustion with best Cardiff coal; there is with some of the Swansea coal, especially with that class of coal which is shipped to South America for copper smelting. Damp promotes combustion.

"No. 2. None in best Welsh coal; no sulphur in it, sulphur necessary to spontaneous combustion; damp no doubt assists. All coals get damp in coming from mine to vessel in open trucks, or they get damp on board; some Welsh coals are certainly sulphury *e.g.*, Dynevor; but never knew a case of spontaneous combustion with best steam coal. Firedamp attaches to even the best coals, which should not therefore be hurried on board ship. Open question as to ventilation of coals after shipment, but hatches should not be closed sooner than absolutely necessary.

"No. 3. There is spontaneous combustion as well as firedamp with some coals; 20 tons of some coals will defile a whole cargo; some coals having much sulphur are bound to ignite though sent no farther than Barcelona. Own (Resolven) coal would not, nor would any of the best steam coal; never knew of it. Has known of explosion with the best coal. That is quite a different matter, and preventable.

" At Newcastle, Sunderland, and Seaham.

" No. 4. Never knew of one case of spontaneous combustion with Cowpen Hartley coal. That was the case of a large cargo for Bombay, which got wet."

" No. 5. Never had a case of spontaneous combustion, combustion does happen when damp gets in.

" No. 6. Has not heard of spontaneous combustion with Wear river coal. Gas coal has sometimes given rise to explosions in contact with flame.

" No. 7. Lord Durham's agent never knew a case with their coal. 'Fiery heap,' and 'duff heap,' has been known to take fire of itself.

" No. 8. Never knew of spontaneous combustion of North Country coal, except with gas coal on long voyages."

The small coal seems to be more liable than lumps.

2. From these notes it would appear that danger from firedamp or the gas which clings to all coal whatever, is serious and certain to manifest itself where the coal freshly wrought has been hurried on board and quickly confined and flame has been allowed to come in contact with the escaping firedamp. This seems however to be a preventable danger. It has not shown itself in any of H.M. ships or depôts. It is, moreover, quite distinct from spontaneous combustion.

That occurs with coal. Welsh or north country, in which any large quantity of sulphur may be contained, is attested by much experience. It seems to be unknown in connexion with the best Welsh steam coal, and nearly so in connexion with best North Country, though Mr. Fothergill, the fitter of the Cowpen Hartley Colliery, furnished the only instance given in these notes of combustion which took place in some of their coal accounted the best in the North. Liability to spontaneous combustion seems to turn upon the greater or less amount of sulphur contained in a coal. Sulphur in some degree and in some shape exists in all coal. Its presence in a large degree is indicated by yellow patches of sulphide of iron, commonly called "brasses," whereof 3,500 tons were stated in a recent letter from Mr. Hunt, of the School of Mines, to have been picked out of coal in the northern district in one year. These "brasses" exist also in Welsh coal, and it is reasonable to attribute their absence in cargoes shipped on Government account, as much to the vigilance of the inspection by the Government Inspector there (now Mr. Traill), as to any original purity of coal, or of intention on the part of coal owners. The elimination of "brasses" from north country coal shipped on Government account, and prevention of shipment of sulphur-bearing coal, would be one of the most useful and desirable functions of a coal inspector in the North.

Damp or wet seems to be indispensable to the process of chemical change, whereof one effect is spontaneous combustion. With every care it is impossible to guarantee absence of wet on board ship, or in transit of coal to ship. Even in depôts, especially abroad, it is practicably impossible to ensure perfectly dry storage.

5. It would appear, therefore, that too much care cannot be taken to secure coal for store abroad, and for use in ships, which shall contain a minimum quantity of sulphur.

6. Would it not be as well to ask Mr. Hunt if he can state what is the maximum amount of sulphur permissible in coal, so as to render it safe from spontaneous combustion?

7. Endeavours should perhaps also be made to secure analysis of all the coals used by the Admiralty.

The analyses have doubtless been made, if so, all that will be needed will be to collect the results.

F. W. Rowsell.

H.M.S. "DEVASTATION."

(Explosion of gas in coal bunkers.)

The following is a copy of the report received by the Admiralty of an explosion of gas which took place in the coal bunkers of H.M.S. "Devastation," on 1st June 1874:—

H.M.S. "Devastation," Portland,
1st June 1874.

Sir,

I have to report that this morning an explosion of gas took place on board Her Majesty's ship under my command in the starboard centre upper coal box, under the following circumstances.

At a quarter before 5 a.m., the two cook's assistants named in the margin surreptitiously removed the lid of the escape man-hole of the coal-box, which is immediately abreast of the officers' galley, in the breastwork deck. Hill carried a naked light, and was seated on the deck with his feet in the bunker resting on the coal, and was, it appears, stooping with his light to pick out lumps, when there was an explosion which severely burnt him about the face and neck, rendering his removal to sick quarters necessary.

Frederick C. Captain's Cook's Assistant, and Joseph Curtis, Ward Room Cook's Assistant.

The coal in the bunker was a mixture of two thirds Welsh to one third of North country; it was shipped here on Tuesday last.

The bunker was nearly full, and the explosion was confined to the aperture.

The temperature was 66° Fahrenheit, and there was no indication of heat or damp when the box was searched immediately afterwards.

I have, &c.

Frederick W. Richards, Captain.

The captain of the "Devastation," on being called on to state what precautions were taken to prevent accumulation of gas in the bunkers with reference to Circular No. 44 of 29th July 1869, issued after the case of the "Minotaur," reported as follows:

H.M.S. "Devastation," Portland,
3rd June 1874.

Sir,

The system pursued in the coal boxes in the "Devastation" is as follows:—

Every morning after the decks are finished, the escapes are opened and a Clanny's safety lamp lowered into every lower box; the boxes remain open during the day, and are closed after evening quarters.

For keeping the lids watertight, a soft gasket, soaked in oil and coated with tallow, is fitted to each manhole; these gaskets are removed when coaling, and afterwards the grooves are cleaned, and they are carefully replaced; these precautions were taken after coaling on 26th May before any water was used on the deck, and there was no indication whatever of water having got into the box in which this accident occurred, the coals were and are perfectly dry.

The chief engineer, accompanied by an engine-room artificer, had thoroughly examined the box and gauged the coal for quantity on Friday the 29th, when there appeared to be no indication of gas being evolved.

The "Devastation" has two tiers of coal boxes, the lower are all fitted with water-tight escapes, which are open daily, as I have stated, for about 12 hours.

The upper boxes are fitted with the usual circular manholes, only these run the length of the breastwork decks, and, as a rule, these boxes are not opened on Saturday or Sunday, nor have they been on this occasion since they were closed on Friday evening.

Having in view the rapidity with which the gas must have been generated on this occasion, it would be well if escape valves were fitted to these boxes when opportunity offers, as it is manifest that the lids of coal bunkers cannot always be off on a ship's deck,

Frederick W. Richards, Captain.

The papers were then referred to the officers of the yard at Portsmouth.

The master shipwright's and engineer's department reported as follows:

In compliance with the directions contained in your memo. of the 11th on Comptroller's letter of the 10th inst., S $\frac{5225}{5839}$, and accompanying reports of the officers of H.M.S. "Devastation," respecting an explosion of gas in the upper coal bunkers of that vessel.

We have the honour to report that we are of opinion that had the gratings been used frequently in the deck-plates instead of hermetically sealed covers, as stated, (by putting gaskets soaked in oil and coated with tallow,) the explosion would not have taken place.

In order to prevent a like occurrence, and to avoid the inconvenience of having the covers removed, in the deck within the breastwork, we would suggest that ventilators may be fitted between the beams, as shown in red on the accompanying sketch.

The captain of the steam reserve made the following report:—

In compliance with your minute of the 11th instant on Comptroller's letter, dated 10th June 1874, S. $\frac{5225}{5839}$, desiring me to report my opinion upon the accumulation of gas in the bunkers of the "Devastation," I have the honour to report that it appears from Captain Richards' letter that the bunker lids were left on from Friday to Monday, during which time the gas accumulated.

2. I am of opinion that all bunkers should be fitted with means for the escape of gas, independent of the bunker lids, which should be taken from the crown or highest part of each bunker into the uptake, mast, or ship's side, as might be most convenient in each case, the principle being that each bunker should be fitted with independant means of relieving itself from gas; and I would submit that such means should be fitted to the "Devastation" as soon as possible, and be provided for in the drawings of all ships in future.

The Admiralty then issued the following order dated 27th June 1874.

The Superintendents at Chatham, Sheerness, Devonport, and Pembroke, are informed with reference to the enclosed papers respecting the explosion of gas in the coal bunkers of the "Devastation" that provision is to be made in the ventilating system in all ships in future for carrying off any gases generated in the coal bunkers.

H.M.S. "DAPHNE."

(Explosion of gas in coal bunkers.)

The following is the Report of the commander of the "Daphne" of an explosion of gas which occurred in her coal bunkers on the 11th August 1874:—

H.M.S. "Daphne," Trincomalee,
13th August 1874.

SIR,

I HAVE the honour to inform you that about 6.50 a.m. on the 11th instant, one lid of port after and one of starboard after bunker were blown off, and a flash of flame was observed. Smoke was then seen ascending.

The officers and crew at once assembled at fire stations, the hoses being ready in a very short space of time; but it was not deemed advisable at first to wet the coal.

Parties of men were organised to clear out the coal into a lighter, the smoke continuing to increase, accompanied by heat, and a stoker in shovelling out the coal to the stoke hole, came upon a small portion of burning coal. I then ordered the pumps to be hove round, and in ten minutes the men were able to resume work, occasionally assisted by the pumps.

The temperature of the bunkers reported during the first and middle watches, and also at 6 a.m. was, port bunker, 95°; starboard, 92°; this was close to the seat of fire, and was not considered beyond the usual average, as the main steam pipe runs through the port bunker causing an increased temperature of several degrees to that of the starboard side.

The port bunker is always highest.

The coal (Nixon's Steam Navigation and Davidson's West Hartley two thirds to one third), was got in at Aden in a perfectly dry state, and appeared so on the 11th.

This combustion appears to me to have been caused by some peculiarity of the mineral, and may possibly have been acted on by the temperature of the steam pipe.

I decided to land the greater portion of this coal, viz. 130 tons, and shall give the bunkers a thorough ventilation, embarking only a portion of it for present use in the foremost bunker when I again complete.

I have, &c.
C. E. FOOTE, Commander.

A report having been called for by the Admiral Commanding-in-Chief on the station as to "when the bunker "lids were last taken off" previous to the accident, it appeared that through inadvertence, the bunker lids previous to the accident, had not been lifted off since the 31st July, although it had been the custom to do so every Friday.

The explosion was thus accounted for.

APPENDIX IV.

INFORMATION collected by CIRCULARS issued by the COMMISSION.

A. SHIPOWNERS.

About 250 of the following PAPERS of QUESTIONS were issued to SHIPOWNERS connected with the COAL TRADE.

QUESTIONS TO SHIPOWNERS.

1. Has spontaneous combustion or explosion ever occurred in any of your coal-laden ships?

2. If so, state all the circumstances of each case as fully as you can, on one of the inclosed forms.

3. What system, if any, of ventilation do you adopt for the holds of your coal-laden ships generally?

4. What proportion does the tonnage of your coal cargo usually bear to the N. R. tonnage of the vessel?

5. What kinds of coal have been shipped in your vessels? State the names of the collieries, with seams, and whether double or single screened.

6. How long has the coal generally been taken from the pit before shipment?

7. What precautionary measures, generally, do you adopt in your ships against spontaneous combustion or explosion, and what provision do you make for dealing with fire from these causes should it occur?

8. Have you any remarks to make, or suggestions to offer to the Commission on the subject of their inquiry?

Please write "Confidential" against any of your answers which you desire to be so treated.

The following are some of the REPLIES received to these QUESTIONS.

From Mr. THOMAS HENDERSON, South Shields.

"Columbia." (*See* p. 85.)

1. Only on one occasion, and the report by the commander accompanies this.

3. Never put any ventilators (except on the occasion above referred to, Article No. 1) in our ships' holds, but instruct the captains to keep the fore and after hatches off when at sea whenever the weather allows, so that any gas which may be evolved may escape.

4. From one fourth to one third over and above the net register tonnage.

5. We have shipped all kinds and descriptions from the best Hartley steam coals (from nearly all the north country collieries) down to the smallest smithy coals. Cannot give

the name of any particular seam, as when the ship goes to the spout only know that the coals are coming from a certain colliery, and do not know what shaft they are worked from.

6. Cannot answer this positively; but of late years should say that very few hours elapse between the time of the coals being brought to bank and being shipped in the vessel.

7. Never take any further precautions than named in Article No. 3. With regard to dealing with fire, we are so satisfied that without ventilation it will not occur that we have not given it particular attention, except to point out to any young captains the measures taken by Captain Ramsey, whose report accompanies this.

8. None further than I think ventilation is unnecessary and dangerous, as by bringing the atmosphere in contact with the gases given out of the coals, the agent that is required for combustion is being introduced.

From Messrs. T. Beynon & Co., Newport (Mon.).

"Usk." (*See* p. 86.)

1. Yes, on board the barque "Usk" in 1861. I think this vessel loaded a cargo of smelting coal at Swansea in the usual way, and took fire when at sea, 98 days from loading port.

3. My own opinion is that ventilation in ships laden with smelting coal is of very little use; the above-named ship was ventilated with shafts from each hatchway.

4. About seventy per cent. of the register tonnage over the register tonnage would be about the ship's cargo; thus a ship of 400 tons N.N.R. would carry 680 tons of coal.

5. Both smelting and steam; steam coal generally is double screened on shipment, smelting coal not at all.

6. My experience goes to show that the coal is shipped as soon as possible after being taken from the pit.

7. In steam coal-laden ships I ventilate them; in ships loading smelting coal I endeavour to get the cargo shipped dry and in dry weather.

8. To prevent the spontaneous combustion of coal I would recommend that the cargoes should be shipped in casks or barrels, which would in my opinion be a sure preventative.

From Messrs. T. Beynon & Co., Newport.

"Usk." (*See* p. 86.)

1. Yes.

3. The plan that has been in use at Liverpool.

4. About 60 per cent. over the net register tonnage.

5. Small coal or smelting coal; no well authenticated case has come to my knowledge of ships having taken fire through spontaneous combustion of large double-screened steam coal.

6. Shipped almost immediately it can be sent down from the pit.

7. In ships of mine loading coals liable to explosion from gases, I have always given orders that the hatches are not to be put on until 24 hours after the ship has been completely loaded, and never put on during loading. I never had an accident with this description of coal in any of my ships.

8. I had a barque called the "Usk," 338 tons register, which loaded a cargo of smelting coal at Swansea and sailed from that port for Valparaiso. In July 1863 she took fire when she was out from Swansea 94 days, and at the time distant from Valparaiso about 200 miles. I attributed the fact at the time to the coal being shipped in wet weather, but I forget now the exact circumstances of the case; the captain, however, stated that the first intimation the crew had of the ship being on fire was the great heat that was felt in the forecastle one morning, and upon opening the forehatch to ascertain the cause, the flames burst up as high as the fore top, and the crew had to abandon the ship at once, taking to the boats, not having time to save their effects; they were picked up and taken into Valparaiso; the ship was fitted in the usual manner with wooden ventilators, as was usual then at Swansea.

Since the "Usk" was lost I have sat as magistrate to investigate two cases of ships that were destroyed by spontaneous combustion of their coal cargoes. Both ships were loaded in this port with house or smelting coal; it was shown during the investigation that the weather had been wet when the coals were shipped, and samples of coal similar to their cargoes produced in court were proved to contain a large quantity of iron pyrites; about the same time I had a ship of my own that I loaded here myself with a cargo of smelting coal, made the passage to Coquimbo in 98 days, and in perfect safety, and the captain wrote me that the coal was quite cool during the whole time the ship was discharging. The reason my ship did not take fire, I think, was that I loaded a superior kind of coal that contained very little, if any, pyrites of iron. The two ships that were burnt caught fire when they were out from their loading port between 90 and 100 days. In the course of the investigation alluded to above, the chemist that was sent down by the Board of Trade stated that sulphurous acid gas (I think it was), if introduced into the hold of a ship that was on fire (from spontaneous combustion of a coal cargo), under certain conditions, would extinguish the fire; he described the method, which to my mind appeared cumbrous and expensive; the chemist undertook to demonstrate in a practical manner the value of his recommendation by putting the fire out in the court house, but this he failed to do.

I have thought over this subject of spontaneous combustion of coal cargoes very carefully, and I believe that although ventilation is of great value in cargoes of coal liable to emit gases that are explosive, it is of very little use in cargoes of coal that are liable to take fire from spontaneous combustion; my plan to prevent the latter (and I think it is worthy of consideration) is this:—Stow the coal in ships' holds in barrels, old flour barrels would do; one of the causes of spontaneous combustion in my opinion is that the coal is stowed in a mass, it lies close, and no system of ventilation could be of use; but in the plan I propose of stowing the coals in barrels it would be stowed in small parcels, each parcel isolated, while the air that would circulate between the interstices of the casks would tend to keep all cool; but the very fact of stowing the coal in small parcels, each distinct and protected from each other, would in my opinion be a sure preventative against ignition. I have mentioned my plan to several of my friends who are deeply interested in this question, and they agree with me that the method I propose is an effectual one to prevent spontaneous combustion; they demur, however, as shipowners to the expense that would be incurred in finding the barrels, and the loss that would be sustained by the ship taking a smaller cargo of coal in barrels than she would in bulk. My answer to this is that the loss of one ship (to say nothing of the consequent risk to life) would go a long way to providing barrels, and if merchants are desirous of shipping a dangerous class of goods such as coal, liable in its nature to spontaneous combustion, they should pay a higher freight for its carriage in proportion to more harmless goods, so as to enable the shipowners to take similar precaution to those I have pointed out in order to enable him to carry the coal without risk to life or property, and without entailing a serious loss to himself.

From Mr. William Thomson, Craig Binning, Uphall.

"Joanna," "Wanderer," "Annie Laurie," "May Queen," "Palmyra." (*See* p. 87.)

1. Yes; in five cases.

3. When the quantity of coal is a mere ballasting no ventilation; when a full cargo is taken the ships are carefully ventilated with wood, up and down each hatch.

4. When ballasted under register tonnage a full cargo about 25 per cent. above the register tonnage.

5. Duke of Buccleuch's Midlothian coal, all screened; Cowpen, Hartley, and Lancashire screened.

6. Unknown.

From Messrs. Charles Hill & Sons, Bristol.

1. No case of explosion; a cargo of smelting coals heated very much, but did not ignite.

3. All our ships intended to carry coals are fitted with a platform, 18 inches or more off the bottom, and 2 to 3 feet at bildges, and have ventilators as follows, viz., one large galvanized iron, one through the top gallant forecastle down to lower hold with bell-mouth at top, and one, sometimes two, smaller ones as far aft as they can be placed. Wood ventilators through each hatch with lapping battens (similar to venetian blinds) so that they cannot get choked.

4. 35 to 45 per cent. over net register tonnage.

5. All the different kinds of steam coal loaded at Cardiff and Newport, also some cargoes of smelting coals, and a few cargoes from the North of England.

6. Coals are generally shipped shortly after leaving the pits, and it frequently happens that that the loading is interrupted waiting for coals to come down from the pits.

7. Each ship supplied with a Davy's patent safety lamp (same as used in coal mines,) and instructions given that no other light is to be used in the ship's hold or store-rooms under the main deck; a portable fire engine and plenty buckets supplied each ship. The captains are instructed

to go below frequently and examine the cargo and test the heat of same with thermometer.

8. I attach much importance to the keeping the *bottom* of a coal cargo *dry* and *cool*, and hence consider a platform most essential. Cargoes of coal are looked upon as not liable to damage, and are generally loaded right on the bare ceiling as no other cargoes are, and the bottom of the cargo is often wet before leaving the docks, strict attention to the pumps not being considered necessary with a coal cargo; ventilators, too, are much neglected, an impression prevailing amongst shipmasters that they are of no use, and they are often fitted in a carelessly and inefficient manner just to comply with the charter, frequently only a few feet in length so as to show at the hatchway. They should be fitted from the bottom and to project above the hatchway, and be piled round with knobs of coal as the loading progresses, to keep them from being choked with small coal. I may be permitted to mention that during the last 10 years we have carried 75,000 tons of coals south of the Equator, mostly round the capes, in ships 400 to 1,700 tons register, and the before-mentioned is the only approach to an accident connected with the cargoes. Last year one of four vessels took a cargo of 1,750 tons Merthyr steam coals from Cardiff, called with it at the Cape and Point de Galle (for a market,) and finally it was discharged at Singapore after being six months on board the vessel.

From Mr. E. S. HILL, Cardiff.

"Her Royal Highness." (*See* p. 87.)

1. Only one case of inconvenience by heating ever occurred with all the cargoes our ships have carried.

3. The cargo is stowed on a platform from 18 to 24 inches from the skin. We place a wooden shaft in each hatchway, and an iron ventilator in each end going down into the main hold. The captain is instructed to keep the hatches open as much as possible.

4. Something over a tonnage and a third.

5. Mostly steam coal double-screened from Nixon's Navigation, Powell's Duffryn, and others of the principal steam collieries, with a few cargoes of smelting coal, and some from the north.

6. It is not possible to answer this question as a matter of knowledge; but I believe, as a rule, large coal is shipped within 36 hours from its being taken from the pits, sometimes much quicker; small coal would usually be longer.

7. Vide reply to No. 3. In addition, the ships are all provided with Davy's safety-lamps and portable fire engines. The captains are told to carefully notice the temperature of the cargoes.

8. I think that the losses by reason of fire in coal-laden ships have been very much exaggerated, and in support of this opinion I have the honour to enclose for the information of the Royal Commissioners a paper which I compiled bearing upon this subject, and which was adopted, printed, and circulated by the Cardiff Chamber of Commerce.

It is an established fact that the Welsh steam coal is not liable to spontaneous combustion. No case has ever been known, but it is very liable to generate gas of a highly explosive character. To prevent accidents it is only necessary to observe the precautions already described.

I have known of several cases of explosion, but I believe in each instance a naked light has been incautiously used.

In the case of small coal and smelting coal I do not consider ventilation desirable. It may be desirable to stow the cargo on a platform for the sake of keeping it dry, but I attach more importance to preventing it getting wet whilst shipping, and of taking care to keep it dry afterwards. The practice of throwing greasy slops on top of the cargo is very much to be deprecated.

From Mr. WILLIAM BUCHANAN, Greenock.

"Royal Family." (*See* p. 87.)

1. In one ship.

3. No particular system. Generally when ventilated in the shafts down each hatch, and sometimes with a trunk along the keelson; never had any heating when no ventilation used.

4. Fully register tonnage and third.

5. Do not know the names of the collieries, but have carried coals to India from Newcastle, Cardiff, Birkenhead, Glasgow, and Greenock, both single and double screened.

6. Don't know.

7. None excepting carrying a fire engine.

From Mr. J. H. WATT, Glasgow.

"Persia." (*See* p. 88.)

1. I may have owned about 30 ships at different periods which have frequently loaded coals, and have had only one case of combustion.

3. Wood ventilators.

4. About 140 p.c.

5. Chiefly from Lanarkshire, also Ayrshire and Wales.

6. Immediate shipment.

7. As a rule my ships were not insured. I have studied the subject carefully, and though the ships were ventilated I rather objected to it, and cannot give any suggestion to prevent such accidents.

From Messrs. J. BRYMNER & CO., Greenock.

"Glaramara." (*See* p. 89.)

1. Only in one about five years ago.

2. See form.

3. Ventilators in each hatch.

4. Varies say about register and third.

5. All kinds, Welsh, English, and Scotch.

6. Generally fresh.

7. As thorough ventilation as possible, and supply fire engines.

8. Except that great care should be taken in loading and proper ventilating.

From Messrs. STODDART, BROTHERS, Liverpool.

"Vanda," "Mondora. (*See* pp. 8 95.)

1. Yes.

2. "Vanda" and "Mindora" herewith.

3. Wood trunk along lower hold, and connected by upright trunks to the hatches.

4. Various. About one third to one half over the registered tonnage.

5. See paper herewith.

6. Cannot say.

7. Fire engines.

8. Cannot give any reason for fire breaking out. Do not think present system of ventilation is right. Water gets down the shafts. Becomes heated and the draught carries smoke up the shafts and feeds the fire.

From Messrs. HINE, BROTHERS, Maryport.

"Cereal." (*See* p. 90.)

1. Yes.

3. Very shallow ships, none. Deeper ships, on each side keelson with shaft communication through each of the three hatches.

4. In steam ships it depends upon the quantity of bunker coals shipped, and this depends upon the length of the voyage; including bunkers about double net register. In sailing ships 40 to 60 per cent. above net register.

5. Various kinds, in nearly all cases double screened.

7. Fire engines.

8. Coals (South Wales) have been shipped in my vessels under the same circumstances of weather, &c., as in the case of the "Cereal," but no symptom of fire showed itself, although the voyage was 40 days longer. I am therefore inclined to think that you must look to the nature of the coals themselves for the cause of so much spontaneous combustion. I am disposed to think there are some kinds that will take fire however dry they may be shipped, and however well ventilated. I never heard of a case of spontaneous combustion of coal shipped from this district (West Cumberland), and such a thing as a colliery explosion is rarely if ever heard of here. I merely name this to substantiate the opinion I have given.

I do not approve of the present mode of ventilation as I think the ventilators in the case of fiery coals act more as flues or draughts for the flames. In my judgment the most effective mode would be to divide the cargo into lots or sections entirely separate from each other by means of bulkheads extending from the bottom of the hold to the upper deck or to the top of the coal, such bulkheads to be double, say a foot apart, with sufficient cross pieces to prevent their being crushed together by the weight of the coal.

The objections to this plan would be its great costliness and the difficulty in carrying it out in ships with 'tween decks laid. The great advantage would be instead of having a large cargo lying in one mass in a ship's hold there would practically be two, three, or it might be four distinct lots with an open space of one foot between each.

I think the next best plan is to lay the fore-and-aft ventilators not in the very bottom of the ship on each side the keelson, but about halfway to the deck, say under the 'tween deck beams, thereby carrying them right through the centre of the mass of coal, where the heat always generates.

I also think it unwise to ship the coal as is now frequently done straight from the mines.

From Mr. William Laing.

ivouac.”
e p. 90.)

1. Yes. One instance of explosion, and one of spontaneous combustion.

2. See enclosure.

3. Permanent galvanized iron ventilators are fitted into each hold or compartment, one at each end of it.

4. Variable, about 11 to 7, exclusive of bunkers.

5. Nearly every kind shipped either at Newcastle or Cardiff has been carried.

6. Generally fresh from the pit.

7. The complete system of ventilation as above mentioned, and my ships all being steamers, are fitted with the usual engine pumps and ample length of fire hose.

8. I consider no coal-carrying ships safe, unless permanent iron ventilators with cowled tops are fitted into each hold or compartment, one at each end of it, forming down and upcast channels; further that naked lights should not be used in the holds on the voyage, as the gas has a tendency to accumulate in any empty or half-filled hold, especially at the fore end of the ship.

From the Secretary of the Swansea Merchant Shipowners' Company, Limited.

Alpha,”
Henry
ath.”
See p. 90.)

1. Yes, in the barque “Alpha.”

2. She was laden with smelting coals for Valparaiso and orders. The coals fired when she was near Cape Horn. The ship was taken with difficulty to Stanley and partially discharged. An agent was sent from England who repaired the ship, and she proceeded to her destination.

3. To fill in between the keelsons or platform risers and level a little below them, lay the platform and place boards (trunk boards) fore and aft on either side of the midships stanchions, allowing of ventilation in both cases.

4. Generally the full cargo of coals, about register and half gross tons.

5. Smelting and steam.

6. Shipowners as a rule do not know.

7. The above-named for ventilation to comply with conditions of charter, relying not on that, but on the subdivisions of the cargo by same means. Steam coals are explosive, and should be ventilated, or at least the hatches should not be closed for, say, 48 hours. After that there is little escape of gas to be feared. Ventilation will not arrest the tendency to spontaneous combustion, but it will aid it when once set in. In that case the ship is closed up generally as a first attempt to smother the fire, but water has to be resorted to almost invariably.

8. Not more than is embodied in the above replies to questions.

From Messrs. R. & J. Craig, Glasgow.

“County of
Nairn,”
“County of
Perth.”
(*See* p. 90.)

1. In two spontaneous combustion, the “County of Nairn” and “County of Perth.”

2. Fully stated as requested.

3. Ventilation through the main deck and one to bottom of hold.

4. Never more than N. R. tonnage of the vessel.

5. Roughrigg and Hamilton coal is always double-screened.

6. Direct from the pits.

7. Ventilation only. Leather fire hose in connexion with two rocking centre fire-engine pumps.

8. The only suggestion we can offer with a view to prevent spontaneous combustion is to build the ships in compartments of such size as to carry not more than 300 or 400 tons in each.

“Prince
Alfred.”
(*See* p. 91.)

1. Two vessels, one total loss, the other put into Monte Video and took out cargo.

3. None heretofore, but would certainly prefer trunks at certain places.

4. About 75 per cent.

5. Both Welsh and North country, but have never known but one case of my own of North country, a cargo for Hull.

6. Shipped immediately.

7. Have not previously adopted any, but should do so if loading these coals again.

7. I shall be glad if my evidence would in any way assist to prevent such destruction of property, but would suggest that the captains of these vessels should be examined. I believe their evidence of much more importance than mine.

From Messrs. J. Kerr & Co., Greenock.

“Isabella
Kerr.”
(*See* p. 92.)

1. Yes, in ship “Isabella Kerr.”

3. A wooden ventilator up each hatch, and one along keelson.

4. About 1·40 per cen

5. Main ell and splint coal.

7. Ventilation as above, and captains have instructions to open hatches in fine weather, and try heat by thermometers twice every day.

From Mr. Charles Beades, Lancaster.

“Channel
Light.”
(*See* p. 91.)

1. Yes; “Channel Light,” at Rio, October 1873.

3. Trunks fore and aft. Ventilation through deck and hatches.

4. 553 N. R., cargo 700 to 750.

5. Welsh or North country coal.

6. A short time only.

7. Ventilation. Force pump, hose, &c.

8. Allow no coal to be shipped until sufficient time has elapsed to allow of the gases to escape.

From Mr. J. S. Greive.

“Walter
Baine.”
(*See* p. 92.)

1. Yes, on board ship “Walter Baine,” lately destroyed by spontaneous combustion. Crew saved.

2. See Rundell's book, page 46.

3. Ventilators in each hatch running along keelson by a tunnel, but I do not approve of it.

4. Generally 100 to 200 tons less than tonnage and half of net register.

5. Wishaw and Sunderland.

6. Cannot speak as to this.

7. Ventilators in each hatch; have not employed any other means.

8. Doubt very much whether the ventilators are not positively injurious. I have a strong opinion coal should be shipped dry. High-valued ships are practically shut out from taking coal charters on long voyages, because of the high rate of insurance on the ship; as a rule low-classed wooden ships must be employed, probably lengthening the passage, and consequently the risk of spontaneous combustion will be increased.

From Mr. George Duncan.

“Persia.”
“Indian
Empire,”
“Khersonese,”
(*See* pp. 91, 92, and 97.)

1. Yes, in three cases.

3. Longitudinal shaft on each side of keelson and upshafts connected therewith coming out of each hatchway.

4. About 30 per cent.

5. Have carried all principal Hartley steam coal from Tyne and Wear, and from the chief collieries in Cardiff.

6. Cannot say, but believe much less time than formerly.

7. Cargoes ventilated, and ships provided with fire engine and head pump.

8. Being member of Commission can do so orally.

From Messrs. W. & R. Wright.

“Mooresfoot.”
(*See* p. 93.)

1. Yes.

3. In all our wooden ships we have a wooden platform under the coal, and venetianed upright shafts which extend from under platform to top of each hatch.

4. This depends upon the model and age of the vessel and the voyage. Our last built wooden vessels are built with a view to carry large dead weight cargoes, and as a rule carry fully tonnage and half. Iron ships usually carry about tonnage and one third.

5. Wishaw coals from Dundee, West Hartley, from Shields, Lancashire, from Liverpool, North and South Wales, from Birkenhead.

6. We believe three or four days.

7. None but the above system of ventilation, which we have adopted for a long time now; it has acted well, and is in favour with underwriters. Engine hose, and buckets.

8. Merely this, that if our plan of platforming and ventilating was universally adopted the number of cases of spontaneous combustion would undoubtedly be diminished.

From Mr. W. R. Price, London.

“Oliver
Cromwell,”
“Calcutta.”
(*See* p. 94.)

1. Have had two cases of spontaneous combustion and total loss, say, ships “Oliver Cromwell” and “Calcutta.”

2. Both ships sailed from Shields for Aden. The “Oliver Cromwell” on the 18th June, and the “Calcutta” on 2nd July 1874. The “Oliver Cromwell” was burnt on 6th September 1874, in latitude 37° S., longitude 14° E. The “Calcutta” was burnt on 17th September 1874, in latitude 35° S., longitude 7° E., being respectively 80 and 77 days out. In both cases the fire was discovered in the main hatch ventilator.

The captain of the “Calcutta” was lost, so no protest giving exact particulars has been obtained; but from some of the men saved, I learn that there was no indication of fire till immediately before it broke out.

In the case of the “Oliver Cromwell,” I have been told that there was no smell of gas prior to the fire, but that a peculiar vapour was noticed from time to time coming up he ventilator some days previous to the fire, which, however, was considered as simply indicating the ordinary sweating of the cargo.

3. Both ships were well ventilated by 4-feet ventilator from the top of keelson to the ceiling, and two horizontal ventilators of wood on top of beams a foot square midway between 'tween deck stanchions and the side of ship. These were connected with three 18-inch upright shafts going through each hatch, the sides of which were arranged like a venetian blind when two thirds open. This is the same system I have adopted successfully for 17 years with coal shipped from Birkenhead to the East.

4. The "Calcutta" was 1,372 tons net register, and had on board 1,802 tons coal. The "Oliver Cromwell" 1,112 tons register, 1,616 tons.

5. The coal in these two cases was, I believe, Howard's West Hartley, shipped on account of the Peninsular and Oriental Company. I cannot say whether it was screened or not, but should think it was shipped as screened, although I noticed a considerable amount of small coal in the main hatchway in the lower hold of the "Oliver Cromwell."

6. I believe the coal to have been taken recently from the pit, but I have no exact evidence on the point.

7. My captains have always been instructed to keep the hatches off whenever the weather permitted, and have always been supplied with plenty of good hose and a force-pump for working same.

8. Having carried coal largely during a period of 17 years from Birkenhead to the East without even a heated cargo, and having shipped it by tips as well as by barrows, I am led to the conclusion that in the losses above referred to there must have been some speciality in the coal rendering it more liable to spontaneous combustion than the North Wales coal, and this view is strengthened by the fact that at the same time two other vessels loaded in the same dock, I believe with the same coal, one of which, the "Euxine" was also burnt, making three out of four ships. The matter is specially referred to in a report from one of the officials of the Peninsular and Oriental Company to the directors (copy of which I enclose*), and I commend to your notice the fact that the fourth ship the "Cora" was not ventilated through the coal, and arrived at her port, although a portion of this cargo got wet with rain and hail during loading, and was therefore more liable to heat.

I have been told by the members of the crews of the "Oliver Cromwell" and "Calcutta" that the seat of the fire in each case was well down in the lower hold under the main hatchway, and as the bulk of the cargo is shipped in this hatchway, there is necessarily a greater density in the mass and a larger accumulation of small coal.

The height of the tips from which it was shipped in the Tyne has a tendency to break the coal, and make the mass less impervious to ventilation in that region. The captain of the "Oliver Cromwell" told me that his ventilators were perfect in their action, as he frequently examined them and found that a current of air passed through them up the shaft.

I entertain a decided preference for the mode adopted at Birkenhead of loading largely by barrows instead of by tips, as the coal is more carefully handled and it is stowed more gradually over the hold, besides which the labourers employed have the opportunity when shovelling it into the barrows of picking out all objectionable looking pieces, which I believe they do. I have shipped it from Birkenhead at all seasons of the year, and when it has been saturated with rain in the railway trucks, without any detriment except loss of weight on delivery.

I have had no previous experience of coal from the Tyne, never having had ships loaded there before.

I would pointedly call your attention to the close approximation in the number of days from sailing to when the fires occurred, say, "Oliver Cromwell" 80 days and "Calcutta" 77 days.

From Messrs. W. & J. Smith, London.

"Eeta," "Enthusiaste," "Try," "Crystal." (*See* pp. 94-97.)

1. Yes, in two partly owned by ourselves, and two chartered vessels. Our ships were "Crystal" and "Eeta" chartered were "Try" and "Enthusiaste."

3. Our vessels being employed in the sugar trade, have ventilators fore and aft. We know of nothing better for coals, but we do not generally carry full cargoes of coal.

4. Never take full cargo except purchases and charters not under our management; by this we mean in our own ships.

5. Given on separate papers.

6. Six to ten days.

From Messrs. Agacio & Co., Liverpool.

"Alexandre." (*See* p. 94.)

1. Spontaneous combustion has occurred.

3. See enclosed form.

From Mr. J. E. Burgess, Swansea.

"Admiral Fitzroy." (*See* p. 95.)

1. Yes.

3. When loading smelting coals I generally have the main body of the cargo, say from abaft the mainmast to the foremast, divided by running up deals on either side of hold stanchions from keelson to main deck, leaving it open at the top.

4. About 45 per cent. over N. R. tonnage.

5. Smelting coals through and through as worked from the collieries.

7. Nothing more than as given at No. 3.

From Mr. Thomas Law.

"Dumbartonshire." (*See* p. 95.)

1. No, only in "Dumbartonshire" with 540 tons balance of cargo, general.

3. 'Tween deck beams longitudinal; also keelson ditto; and the three hatches perpendicularly.

4. 50 per cent more.

5. All kinds from Cardiff, Birkenhead, and Clyde.

6. Don't know.

7. We take no precautions except ventilating.

8. No.

From Messrs. Hughes & Co., Menai Bridge.

"Glen Tilt. (*See* p. 96.)

1. Yes, combustion by one ship.

3. Our wooden ships invariably carry platforms open at both ends, and the opening kept clear to main deck ventilators, and our iron vessels are so constructed that they afford ample ventilation.

4. Once and a fourth of the register tonnage.

5. Mostly steam coals.

6. Cannot reply.

7. Ventilation as described above. Answered in the enclosure.

From Messrs. Seed, Armstrong, & Co., Liverpool.

"New Lampedo." (*See* p. 97.)

1. Yes, in one.

3. Platform and deck ventilators.

4. Register and third. Sometimes a little over; varied according to ship I am loading.

6. Cannot say.

7. Caution master to leave hatches off at all times when practicable. Have had nothing but fire engine and hose.

From Mr. D. Stuart.

"Staffordshire," "Monmouthshire." (*See* p. 96.)

1. Spontaneous combustion has occurred twice.

3. The ordinary system wooden ventilators.

4. In the first case the quantity of coals was two thirds of the registered tonnage.

In the second case it was the entire cargo.

5. Lancashire steam coals. The White Moss Colliery single screened.

6. I do not know, but I fancy immediately.

7. This I have left to the management of the captains.

8. None.

From Messrs. Balfour, Williamson & Co., Liverpool.

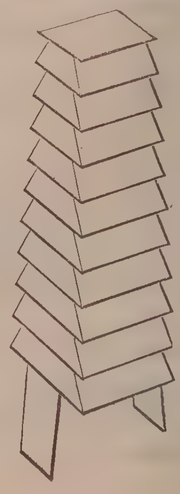
"La Escocesa." (*See* p. 97.)

1. Yes.

2. Once in ship "La Escocesa."

3. Fore and aft along keelson, and three vertical ventilators so constructed as to prevent admission of small coals, and at same time grant free exit to gas.

Vertical ventilators constructed as per sketch:—



---

* This report of Captain Steinson's was read by Mr. Price before the Commission, and will be found in his evidence, Q. 1202.

4. About 45 per cent. over register tonnage.

5. Lancashire, North and South Wales coals.

“La Escocesa” was loaded in Cardiff with South Wales coals fresh from the pit, and raining heavily while she was loading.

6. Of late years only a very short time before shipment.

7. Hatches off during fine weather at all times. Fire-engine, hose, and buckets always on board.

8. Coal-laden ships should either be ventilated properly or not at all. If only partially ventilated, and heating should take place, the partial ventilation causes them to burn rapidly. If not ventilated at all, they may occasionally be kept smouldering for weeks, and thus give the ship an opportunity of reaching some port.

From Mr. E. Bates.

“Euxine,” “The Foundling.” (*See* pp. 93 and 98.)

1. “Euxine” and “The Foundling.”

3. Generally a ventilator run fore and aft through the coals, of wood connected with a perpendicular shaft in each hatchway.

4. Varies according to the vessels, “Euxine” 5 to 4. Usually about one third more than the register tonnage.

5. Almost all kinds exported at various times.

6. Unknown.

7. Have never had a case of explosion. Ventilation prevents this; and have never had a case of combustion until last year, 1874, when besides the above known cases we have lost two other coal-laden ships which have not been heard of, and are “missing.”

From Mr. D. Kennedy, Liverpool.

“City of Richmond.” (*See* p. 98.)

1. Yes.

3. Platformed.

4. 25 per cent. to 30 per cent. more than the register tonnage.

5. Different collieries “said” to be double-screened.

6. A few days if loaded in the Mersey, a shorter time if in the Tyne.

7. Ventilators up each hatchway, and orders to have hatches off in fine weather.

8. Quite at a loss what to suggest. For I say (20 at least) found platform of 3-inch deals from mizen mast foremast with ventilators up each hatch sufficient, but lately have had two ships on fire from coal cargo. Think the quality and character of coal changed.

From Messrs. Elliott, Lowrey, and Dunford, Newcastle-on-Tyne.

“Broomhaugh.” (*See* p. 99.)

1. Yes, in the case of the S.S. “Broomhaugh.”

3. Since the accident above steamer has been fitted with ventilators in the holds, but generally our masters are instructed to uncover the hatches whenever the weather will permit.

4. Our cargoes average ·87 over the N.R. (this of course includes fire coal).

5. Our steamers have carried nearly all kinds of Welsh and North country steam and gas coals.

6. Our impression generally is that coals are shipped within, say, 12 to 24 hours of being worked.

7. As explained above our captains are instructed to remove hatches in fine weather.

Our ships are furnished with rivetted leather hose of sufficient length to reach all parts, of the ship, besides being provided with a proper complement of water buckets.

8. Apart from explosion on board a coal-laden ship from extraneous causes, as in our case, we are inclined to the idea that too little attention is paid to the shipment of coals in vessels going long voyages.

With reference to ventilation, provided coals are shipped and kept in a dry state we would certainly look upon it as a preventive against spontaneous ignition; but on the other hand, should they be shipped after being exposed to rain, or from wet workings, we fancy ventilation would rather assist combustion than otherwise.

From Messrs. Livingston, Briggs, & Co., 31 Great St. Helen’s, London.

1. As owners none. As charterers for the Peninsular and Oriental Company, we believe several have been burnt, but whether by spontaneous combustion or otherwise we are unable to say.

2. These can be better answered by the owners or masters of the vessels.

3. Ventilation is adopted and stipulated for in our charters, but we are unable to state the exact means. This is left to the owners and the Peninsular and Oriental Company’s inspectors at the loading ports.

4. About 40 per cent. to 50 per cent. over.

5. All descriptions, namely, Powell’s Duffryn, Ocean Merthyr, Letty Shenks, North Wales Main Scotts Brymbo, West Hartley Main Carrs, Davidson’s, Howard’s, Bower’s and Bebside’s Hartley.

6. Sometimes the same day, but generally a few days before.

7. This is left entirely to the masters of vessels.

8. Nothing especial, we believe. It is more a question for chemists.

From Mr. C. Thompson Wigram, Blackwall Yard.

1. In one case.

2. The coal was taken direct from the pits into the ship’s hold in wet weather at Cardiff, and subsequent bad weather prevented the hatches being kept open at sea.

3. We do not take any special precautions to ventilate the coal bunkers of the steamships in which coal is stowed in bulk to the extent of three or four hundred tons. The coal is never taken direct from the collieries to the ship’s hold.

5. Nixon’s Navigation, and Hartley’s.

6. Ten to fourteen days.

7. No special precautions are taken beyond those adopted for the general protection of the ships from fire.

From Messers H. Fernie & Co., Liverpool.

1. No.

3. System of ventilation explained in accompanying letter.

4. From one fourth to nearly one half in excess of the N.R. tonnage according to the build of the different ships.

5. From Birkenhead and Cardiff the usual diversities of North and South Wales steam coal. From the Tyne, principally the West Hartley.

6. When shipped from Birkenhead we should say from two to three days. From the other parts we believe considerably less time.

7. Having taken such thorough precaution to prevent any fire by ventilation, we have hitherto left the masters to divise any special means of dealing with fire if it did after all arise.

8. We believe that if all coal could be exposed to the influence of the air for two days before shipment the risk of spontaneous combustion would be decreased.

Sir, Liverpool, 27th May 1875.

In reply to your letter of 24th instant we beg to state that in the interval from 1866 to end of 1874 we had despatched 49 large ships fully laden with coals to various ports of India and South America, and that every one of these ships carried their cargoes safely although some of them had the coal on board for fully six months.

During all that period we have followed out the one principle of ventilation, though a little varied, in the wooden and iron ships respectively; and, as our system has been so successful, we have thought it best to send you pen and ink sketches of same, marked No. 1 for iron ships and No. 2 for wooden ships, for your further information.

Besides this ventilation, however, we invariably lay a platform of deals secured by spike nails to bearers laid across the bottom of the ship, and extending from the keelson to the lower part of the bilge in breadth, and extending nearly the whole length of the ship. This platform stands about 16 inches above the ceiling beside the keelson, and runs off to nothing at the bilge, and the lower ends of the upright louvre or venetian ventilators rest on the keelson and platform, through which sufficient air holes are bored in the proper places to allow a continual current of air passing along the ship’s bottom all the way from the fore hatch to the after hatch.

We may mention three cases in which we think the value of our mode of ventilation was specially tested.

First, in the case of the ship “Iron Cross,” which sailed from Shields to Bombay on 30th November 1872, and having encountered one of the furious gales of that season off Scilly had her decks swept, and put back to Portland with 9 feet of water in her hold, which had come in through the decks and stanchions being injured, and which had passed through the body of coals, thereby rendering them more dangerous for fire. The ship being refitted reached Bombay on the 2th May, which was 5½ months after sailing.

Second, in the case of the “Royal Alexandra,” which sailed from Shields for Bombay on the 11th September 1874. This ship by inadvertance was laden 5 inches deeper than usual. Her cargo was West Hartley coal (and several ships whose cargoes consisted of that description of coal and sailing very nearly about the same date were burnt), and she made a long passage of 161 days, but her cargo remained perfectly cool and safe until discharged.

Third, in the case of the "Grampian," which sailed from Birkenhead with a cargo of North Wales steam coal on 1st October 1874, and also, as usual at that season of the year, made a very prolonged passage of 158 days, and her cargo was quite cool and safe till discharged.

We may mention that our orders to the captains are very strict, that all the hatches should be off in good weather, so that for a great portion of the voyage in most cases a further and large current of air is brought on the surface of the cargo.

Should it be thought necessary we could have a wooden model made at very little cost showing this plan of ventilation more effectually than by the sketches which accompany this letter.

We are, &c.,
J. M. Carmichael, Esq. HENRY FERNIE & SON.

MEMORANDUM of COAL-LADEN VESSELS.

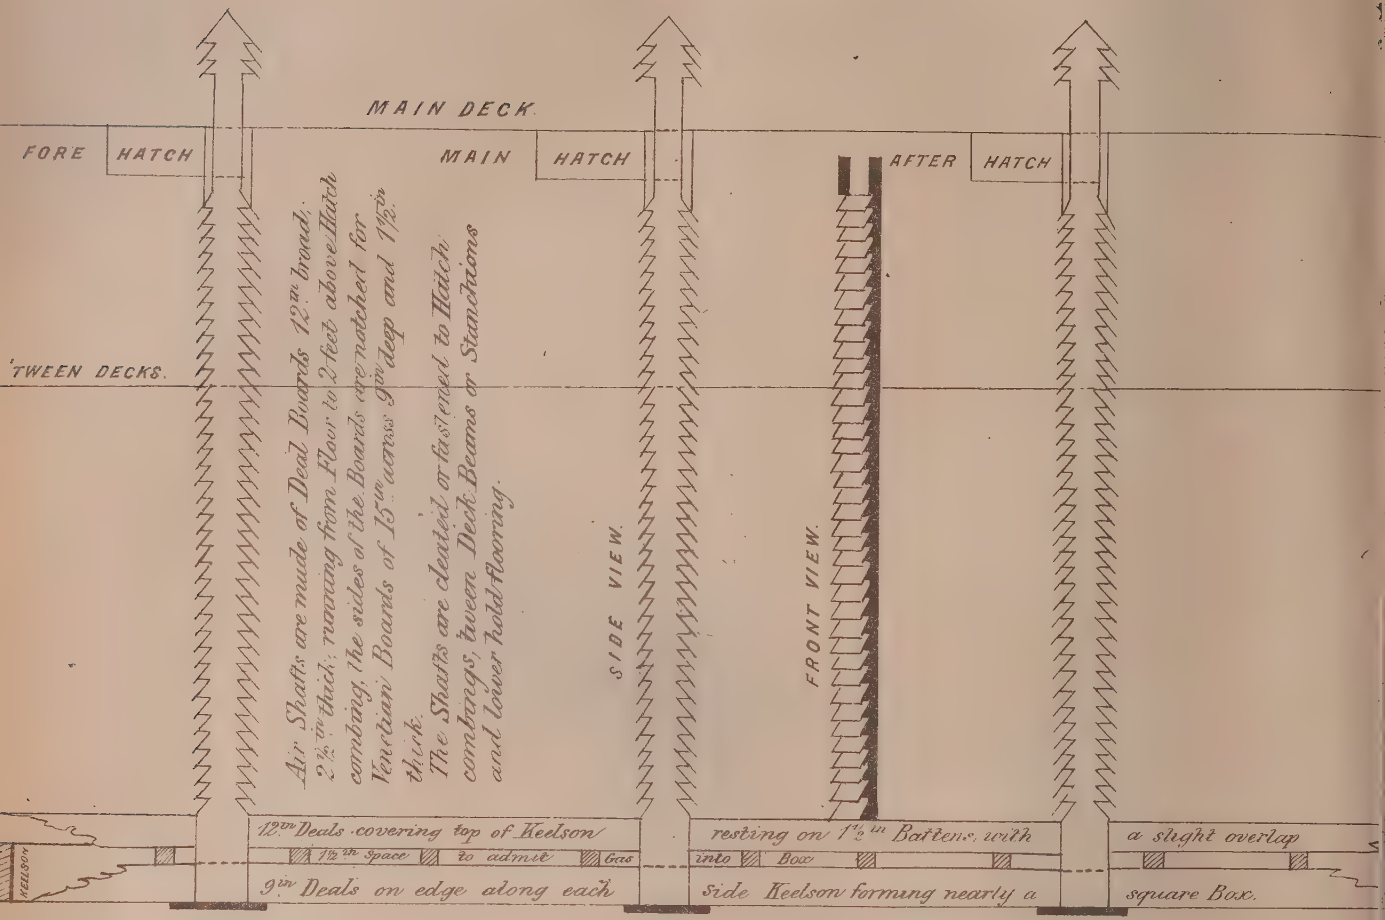
Nº 1.

VENTILATION FOR IRON SHIPS.



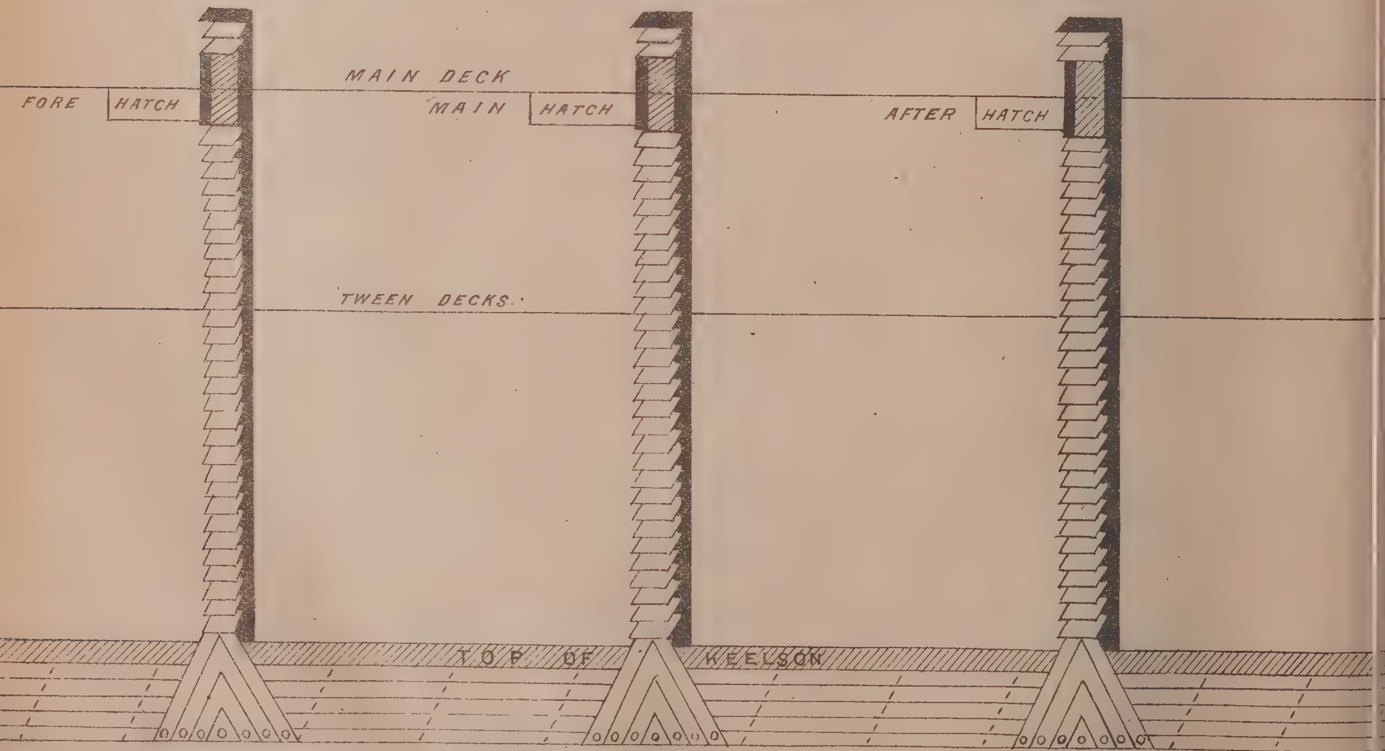
MAIN DECK
FORE HATCH
MAIN HATCH
AFTER HATCH
'TWEEN DECKS.
SIDE VIEW.
FRONT VIEW.
KEELSON
12in Deals covering top of Keelson resting on 1½ in Battens, with a slight overlap
1½ in Space to admit Gas into Box
9in Deals on edge along each side Keelson forming nearly a square Box.

Air Shafts are made of Deal Boards 12in broad; 2½ in thick; running from Floor to 2 feet above Hatch combing, the sides of the Boards are notched for Venetian Boards of 15in across 9in deep and 1½in thick.

The Shafts are cleated or fastened to Hatch combings, 'tween Deck Beams or Stanchions and lower hold flooring.

Nº 2.

VENTILATION FOR WOOD SHIPS, *WITH HIGH KEELSONS.*



Fore and aft Battens laid sloping, with small overlap from 2 feet off bottom of Keelson up edge of Keelson, on pieces Deals notched and forming venetian work, as in above Air Shafts, also large auger holes bored through Timbers & Platform, if any, for escapement of foul air into air shafts.

49	Total number of coal-laden ships.

From Mr. E. T. Gourley.

1. None.

3. Wooden longitudinal spouts with upright shafts.

4. This varies in accordance with the voyage.

5. Every description.

6. This depends upon the coal demand. When the demand is slack colliery owners pile their heaps, and ship them off when trade is brisk.

7. Board of Trade fire engine and hose regulations.

8. That all coal-laden ships for long voyages be fitted with bildge fore and aft, and upright air shafts of wood or metal.

From Mr. H. E. P. Adamson, North Shields.

1. No.

3. The steamers are ventilated in each hold. The 'tween deck ventilators being venetians, with the usual cowls on the upper deck.

4. It depends on the quantity of bunker coals we take on board of our steamers.

5. All descriptions of Northumberland and Durham coals, and some descriptions of Welsh coals.

6. From 12 to 24 hours.

7. The sailing ships we have are engaged in the Mediterranean trades, and are ventilated daily from or through the hatches. The steamers go to India, America, the Mediterranean, and the Baltic.

8, No.

From Mr. John S. De Wolfe, Liverpool.

1 No.

3. Venetian wood ventilators in each hatch, let into fore-and-aft ventilators on each side of the keelson; also in lower hold ventilators from side of ship into up-and-down ventilators; iron masts, pump well, and chain lockers also constructed to act as ventilators,

4. Depends upon the model, &c. of the vessel. Refer to list attached of vessels loaded. Don't take register tonnage into account.

5. Names of collieries unknown. Believe coals generally double screened. Always so when purchased on our own account.

6. Unknown, but we believe generally shipped immediately.

7. Instruct captains to keep off their hatches in fine weather. Supply the vessels with fire engines.

From Mr. J. R. Hawley, Liverpool.

1. No.

3. Wooden passages with upright shoots.

4. Tonnage and third.

5. North Wales and Lancashire steam coals single screened, and cargoes from Newcastle, N. S. Wales, to India, and China.

6. A week to ten days.

7. I have arranged ventilators or passages made and composed of substantial timber planking, open at corners placed and running on each side of the keelsons, similar passages placed 6 to 8 feet up in the body of the coals or fuel along the bildges. All my ships have 'tween decks laid, and I cause similar passages to be carried on each side thereof in the body of the fuel.

The passages all communicate with upright shafts through each and every hatchway, and made of sufficient size to admit a big lad to go down these shafts for inspection. These are kept open in all weathers, but in case of its being very bad have venetian caps to lift on and off.

The cargo is trimmed well up to the decks in the centre of the vessel, keeping a clear space at both ends the which having grating communications also act as ventilators through lower forecastle and lazarettes. Masts when of iron are bored, and are air conductors of great merit. Should fire occur each vessel carries two very powerful force pumps. Fire engines kept ready for use at all times. I carry lightning conductors to each masthead; these have saved the vessels very frequently when struck.

8. No vessel should go to sea without sufficient lightning conductors.

My vessels being high-classed wooden and composite ships engaged in the Indian and China trades, and carrying large and very valuable cargoes, both on my own and general account, ventilation has at all times had my most particular attention, and is essential to safety both to ship and cargo, and is too little attended to.

I never allowed coals to be shipped in wet weather, and I think this is a point that should call for strict attention, particularly so in large and bulky cargoes.

Having run very many times uninsured on my ships and cargoes I was naturally very careful on all their equipment. I consider ships are too lightly manned, and the class of seamen are very deteriorated of late years. I should mention that in 1872 I lost a ship, the "Sea Pink," classed at Lloyd's, just out of graving dock after caulking and re-coppering. She took on board a cargo of coals at Shields for my own account and sailed for Calcutta. Ventilated as noted. She passed the Downs after bad weather, from where I had letters from Captain McKenzie, an old tried servant, stating everything satisfactory, cargo perfectly cool, and little or no difference in the atmosphere of the hold. I have never since heard of him or any of her crew.

I do not attribute her loss in my own mind to fire. My impression is that she was lost in very bad weather off the Cape of Good Hope, in which being afloat she would likely be caught, and Lloyd's list reported a vessel sighted after apparent collision or accident in great distress, the description answering to the paint and of the said vessel. I tried perforated iron ventilators on two or three occasions (Meacock's patent), found the weight of material too great for them to bear, and the iron pipes collapsing practically it was useless.

From Messrs. Adamson and Ronaldson, London.

1. No.

3. If platformed, shafts to same with venetian sides; otherwise dunnage laid each side keelson fore and aft, with shafts as above through each hatchway, besides the ventilation arrangements on the upper deck. Instructions given to officers to keep the hatches off at all times as long as possible, but not to allow the cargo to get wet.

4. About one third over, sometimes a little more, sometimes a little less, according to the dead weight capacity of the ships, which of course vary.

5. Steam coal, gas coal, and patent fuel. We can hardly specify the collieries, but should say from most of the leading ones of Tyne, Cardiff, and Birkenhead. Almost always double-screened, but from what "seam" never comes under our notice.

6. This we cannot say. Shippers only could give this information.

7. Replied to under No. 3. All our ships are supplied with good fire engines, hose, and buckets.

8. We consider if the above precautions are adopted, and the cargo not put into the ship for 24 hours after being in the trucks, there should be little danger. Also that small coal or dust should not be allowed to accumulate in large quantities in the hatchways under the cargo. It stops ventilation, and, if damp, is liable to heat by pressure of the coal above.

From Messrs. H. N. Hughes and Stephen, London.

1. None to our knowledge over a period of say 25 years, during this time having been very heavy shippers.

2. See above.

3. We ventilate our ships as recommended by the Salvage Association Surveyors in slip 221.

4. Large spruce ships carry from 40 to 50 per cent. in excess of registered tonnage on draughts approved of by surveyors. Other wooden ships about 30 to 40 per cent. more than their register tonnage. Iron ships vary very much in their carrying. The best carriers take nearly the same proportion as spruce ships.

5. We ship only North Wales main seam coal from collieries on the list of the Great Indian Peninsular Railway Company, which has been inspected and tested by the consulting engineer of that company. All the coal according to agreement is double-screened, and pyrites are carefully picked out at the collieries.

6. We believe 24 hours is the shortest interval between raising coal from the pits in North Wales and shipment of same at Birkenhead.

7. We consider careful ventilation, as explained in the Salvage Association slip 221, also care in picking out pyrites, both at the collieries and again alongside ships on shipment, and the loading of ships by handbarrows instead of tips, to be the best precautionary measures against spontaneous combustion.

From Mr. James de Wolf, Liverpool.

1. No.

3. A ventilator alongside of the keelson fore and aft each side, and a ventilator from the keelson to main deck in the fore, main, and after hatches.

4. About 50 per cent. above register tonnage; sometimes more, according to the build of the ship, voyage, and season.

5. All kinds of coal double-screened as far as I know.

6. I do not know.

7. I take no other measures than those mentioned herein. I have never had an accident during 30 years' experience.

8. I consider coal taken directly from the pit and put on board ship more likely to ignite than coal remaining on the bank some time before shipment. I disapprove of too much ventilation.

From Messrs. Leitch and Muir, Greenock.

1. No.

3. Wooden ventilators along both sides of keelson and below 'tween deck beams connecting with upright wooden sparred ventilators in each hatchway. Hatches kept open at all times when state of weather admits of this being done.

4. Very nearly tonnage and half.

5. Lancashire Welsh, and Scotch steam. Cannot give the names of collieries. Coal is usually double-screened for shipment to India. The shipments have been made at Birkenhead, Cardiff, and Clyde.

6. Cannot say, but believe in most of the cases it came direct from the pits to the ships.

7. Beyond keeping the hatches open and watching the temperature of the hold, as shown in the state of the air in the ventilators, do nothing else; fire engine and head pumps, with hose for throwing water on the cargo.

8. Suggest fitting shifting boards fore and aft along both sides of hold, stanchions carried up to close beneath the deck, or piling stowwood alongside of the hold stanchions at various parts of the ship.

From Mr. W. O. Taylor, Dundee.

1. Out of nearly 40 cargoes British, and some half-score Australian coal shipped for the East and West Indies, and East and West Coast, South America, I have not had one case of spontaneous combustion or explosion.

N.B. All vessels carrying the above have been under 1,000 tons register.

3. Simply keeping the hatches open when practicable, being of opinion that all other methods have a tendency the opposite of that desired.

4. In most cases say full deadweight capacity.

5. Chiefly steam coal from various collieries, shipped in Wales, the rivers Tyne, Mersey, Clyde, Forth, &c.

6. Different periods, according to the demand and convenience of the sellers, but prefer coals to have been worked some time previous to shipment.

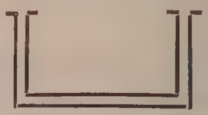
7. None beyond seeing that the coals are shipped in as dry a state as possible, and having proper attention given to the ventilation as above.

8. I am decidedly of opinion that ventilation by wooden ventilators tends to spontaneous combustion, and I believe the first coal-laden vessel that caught fire in this way (the "Humayoon") sailing from Dundee, was the first to adopt the new method of ventilation, say by introducing wooden ventilators amongst the coals.

From Messrs. Edward Shotton & Co., North Shields.

1. Nothing to speak of. In one case many years ago a vessel's keelson was partially burnt. I think she was loaded at Birkenhead. Water was pumped into the vessel and the fire extinguished. This occurred at Point-de-Galle. This is the only case happened to any of our vessels.

3. Ordinary ventilating shaft communicating with each hatch, thus—



4. About one half more; in summer time a little more.

5. Generally steam, but sometimes gas.

6. Generally about two days.

7. A current of air is passed from the fore to the aft hatch by means of shafts. Fire hoses.

8. No hatches should be battened down for some hours after the vessel is laden. Length of time depending on description of coals shipped. Fore-and-aft hatches we have built 2½ to 3 feet high, so that at almost all times excepting when the sea is very heavy they can be open,

This we have practised for from 20 to 30 years, and to this we mainly attribute our escape from the risks above alluded to, for the gas has no means of collecting in sufficient quantity to do damage.

From Messrs. Stuart and Douglas, Liverpool.

1. No.

3. A ventilating shaft, 24 in. by 16 in., constructed of boards with a sufficient space between the boards on each side of the shaft to allow of any gas that may be thrown off by the coal to pass through these gaps into the ventilating shaft, and so be conveyed at once to the outer air, also a chamber of boards enclosing the keelson of the ship from end to end. The shafts above described are fixed into this chamber; one shaft is placed in each hatchway, and the shafts project 4 feet above the top of hatch.

4. Generally about 1⅓. The average of 25 coal cargoes gives 1·225.

5. We have shipped Bower's West Hartley coal from the Tyne, Wigan coal under charter from Liverpool, and North Wales steam coal from Birkenhead. We cannot give the names of the collieries. We believe the coal has in all cases been well screened.

6. The last cargo from the Tyne (and which has arrived safely at its destination) was shipped in about an hour after leaving the pit. The coal shipped at Birkenhead has, we believe, been not less than two days out of the pit before being shipped.

7. Copious ventilation as above shown and having the hatches opened during the voyage as often as practicable, and regular attention to the ship's permanent moveable headed ventilators. For extinguishing fire the ship is provided with fire engine and hose, and set of fire buckets; but we rely mainly upon preventive measures.

8. We have to remark that we attach great importance to the way in which the ventilators are fitted in the ship. We always employ our own carpenters, and spare no expense to have the work done substantially. From the careless way we have seen this kind of work done, we are quite sure it would give way with the pressure of the cargo, thus effectually breaking the current of ventilation, and probably ending in the ignition of the pent-up gas.

From Messrs. Abram Lyle and Sons, Greenock.

1. None.

3. Vertical wooden ventilators in each hatch, and fore-and-aft ditto along keelson.

4. About tonnage and third, varying a little according to circumstances.

5. Principally Wishaw coal, say Watson's, Hartley, and Spencer's splint, double-screened; seams unknown to us.

6. Latterly we understand a very short time, perhaps about a week.

7. We rely chiefly on our strict injunctions to the captains to have the hatches off on every possible opportunity; but if fire should take place, the instructions are to flood the ship by means of a fire engine, and at the same time to keep throwing overboard the coal until the fire is overcome.

8. We think if large stringly-sparred ventilators (vertical), sufficient to let a man easily down, were put in each hatch, they should both give better ventilation than the small ones now in use, and would also, in the event of fire, let a man down to the very bottom of the coal with a hose. A more systematic style of stowing might also do good.

From Mr. G. A. Caws, Northumberland.

1. No.

3. No regular system, only hatchway and deck ventilators.

4. Nearly double.

5. Newcastle, Cardiff, and coals of all descriptions, both double and single screened, and unscreened.

6. A day or two.

7. For long voyages, ventilation through deck and hatches, taking care that the squares of the hatchway are kept clear of coal, and not filled up so as to prevent the escape of gases.

8. For long voyages the coal should be shipped dry and as clear of brasses as possible. Lower deck hatches should be kept off, and the upper deck hatchways kept clear of coal, with ventilators through the decks and hatches to allow a current of air to pass over the top only and prevent the accumulation of gas; cocks to admit water in case of need. Coal ships are seldom properly dunnaged, and the same care is not taken (as with perishable cargoes) to keep the vessel always pumped dry, the water being thus sometimes allowed to get above the ceiling; this would be dangerous with small coal, which would be apt to heat.

From Messrs. Smith, Bilbrough, & Co., London.

1. No.

2. We build a wooden platform rising from 12 to 18 inches above the skin of the ship at the keelson, and 18 to 24 inches above the skin at the bilges, opening at the ends with two small compartments free of cargo, and communicating with two ventilators through the deck. We also have ventilating ladder shafts through each hatch.

4. From one third to one half above, according to the ship's carrying powers.

5. Principally steam coal from South Wales, Newcastle, and Liverpool; also from Newcastle, N.S.W.

We cannot name the collieries as we do not know them; the coals were sometimes double and sometimes single screened.

6. We have no means of telling.

7. We keep the hatches open whenever possible, and we provide all our ships with two fire-engines, one fixed, the other portable. Some of our larger ships have steam engines with which the fire hose can be connected.

8. We consider the principal causes of fire in coal-laden ships are—

1. The coal is frequently shipped in a wet state. The small coal, which retains the moisture longest, accumulates at the loading hatch. In then gets heated in time, and finally ignites.
2. The same thing happens unless the coal is raised by a platform well out of the reach of the bilge water.

We find that our wooden ships have taken about 45,000 tons of coals in the last four years. We have not carried any in our iron ships.

From Mr. George Adam, Greenock.

1. None.

3. Along the keelson and in the three hatches; and some of the iron ships have six ventilating mooring bitts on each side,

4. About one third more than the registered tonnage of the ship.

5. Principally Brymbo Welsh, Hartley steam coal shipped at Birkenhead, and a few cargoes Glasgow steam coal, but I do not know the name of the collieries.

6. Cannot say as the coals are shipped by the charterers

7. Keep the hatches off in fine weather during the voyage, and in carrying to India upwards of 40 cargoes never had any case of fire on board of any of our ships.

8. No suggestion to make further than we have been fortunate with our system of ventilation, which some parties now repudiate; at the same time would recommend that coals should not be shipped without being exposed to the air for a reasonable time after being dug from the pit.

From Messrs. Eyre, Evans, & Co., Liverpool.

1. No.

3. Two shafts fore and aft communicating with shafts up each hatchway, and hatches taken off in fine weather.

4. Generally one third over registered tonnage.

5. All kinds, Glasgow, Dundee, Tyne, Cardiff, Newport, Birkenhead, and Leith, Wishaw, Powell Duffryn, &c.

6. Latterly, say for two or three years, coals have come direct from pit to port of shipment, and have been more liable to heat.

7. Positive orders to masters to examine ventilation closely, seeing there is no heating in the hold, and that temperature in hold is not greater than on deck. We have fire engines and hose always on board, but never required to use them.

8. We believe if masters were particular and coals shipped in a fair dry condition, there would be little risk of fire from spontaneous combustion.

From Mr. W. Turner, Greenock.

1. Never.

3. Trunks in the hatchway to the keelson.

4. About tonnage and third.

5. Shipped coals at Newcastle, Greenock, Birkenhead, and Cardiff.

6. Cannot tell.

7. See No. 3, with this exception, if the masts are iron they also act as ventilators.

8. The last cargo shipped here on board new iron ship "Rossdhu" for Calcutta *were very wet*, and yet no spontaneous combustion or explosion occurred.

From Mr. Joseph Robinson, North Shields.

1. No.

3. None, excepting keeping the fore-and-aft hatches open until the ship gets to sea, and in fine weather when at sea, which allows the gas to pass off.

4. Register tonnage and three fifths.

5. Both gas and steam (see general remarks).

6. I think two or three days.

7. None, excepting as referred to in question 3 (as above). No provision against fire made in the sailing ships, steamers have the usual fire hose.

8. Yes; I would strongly recommend that all coals intended for long voyages, should be covered with tarpaulins in transit from the collieries to the ship, and should only be shipped in dry weather, and as a further precaution ships might be dunnaged. My ship "Gladiolus" has been three voyages to the River Plate, and in each case the cargo was on board about four months. Two of the voyages she had Nixon's steam navigation coal, Cardiff double screened, and on the other she had Scotch coal from Glasgow (no particulars of colliery).

The "Eleanor Grace" has just made a voyage out to River Plate, and has had her cargo in four months, and nothing wrong. It was Nixon's steam navigation and double-screened. She had very bad weather going out Our steamers are principally employed in Mediterranean, and sometimes to India. All the ventilation they have is, from the top of the cargo, the ventilators being fitted on the upper deck only.

From Messrs. J. and A. Roxburgh, Glasgow.

1. No.

3. In North American trade, and from Newcastle, New South Wales, to California or India, have ventilated the cargo only from the hatches. From Britain on long voyages have used moderately-sized ventilating trunks placed longitudinally, and vertically constructed, so as to admit the vapour arising from the coal. Sometimes vertical trunks only,

4. From 20 per cent. under to 50 per cent. over the net register tonnage, according to the build of the ship, the voyage, the season, and the prospect of a profitable return for carrying the coal.

5. From Clydesdale pits; Davison's West Hartley steam coal.

6. Generally fresh from the pit.

7. Ventilation as above, and instructions to captain to keep the hatches off in fine weather.

8. Ventilation as far as it provides for the escape of foul air is good, but we think it has been overdone in some instances, and that the current of air introduced into the hold may have been the immediate cause of ignition.

From Messrs. William and Alfred Brown & Co., Glasgow.

1. No.

3. In addition to the ordinary deck ventilation we have from three to five shafts, each about 2¼ feet square, latticed on two sides. These shafts run from the keelson to about 3 feet above the deck. A fore-and-aft current is also obtained by laying stout slabs along the keelson. Windsails are set on the forward or after shaft according to direction of wind.

4. From 20 to 50 per cent. in excess of net register tonnage.

5. Chiefly steam coal, double-screened when shipped at English or Welsh ports. Cannot say as to screening in Clyde. Cannot name collieries.

6. Generally understood to be fresh wrought.

7. Thermometric observations daily to ascertain whether heat is being generated in the hold (a copy of results recently received is attached hereto). Means for dealing with fire are confined to force pumps, of which in large ships we have three. In the event of heat increasing greatly in the hold, very frequent observations are to be made with the thermometers, and the master is instructed personally to descend the shafts and endeavour to ascertain the condition of the cargo. Should it appear probable that combustion has commenced or is likely to break out, the force-pumps are to be rigged and the coals deluged with water, the steam-winch keeping the ship free by means of the main and bilge pumps. Should this not check combustion, cargo is to be jettisoned so as to give buoyancy for a more thorough flooding of the hold, and the ship is (if possible) to bear up for a port and there be scuttled.

From Messrs. T. Davies & Co., Swansea.

1. No.

3. Upright clinker-built ventilators in two hatchways, sometimes horizontal under the beams.

4. From one third to one half above the register tonnage.

5. Bituminous coal for smelting purposes.

6. Generally fresh wrought.

7. Nothing except ventilation, but I attach no importance to ventilation.

8. If the coal is clean, free from dirt, sulphur, and iron pyrites, it will carry even if shipped in wet weather; if not, even if shipped in dry weather, it will probably heat.

From Messrs. J. Morrison and Son, North Shields.

1. No.

3. Hatches kept open frequently.

5. Steam coals double screened.

6. Probably two or three weeks.

7. Only adequate ventilation.

8. Yes. The present system of ventilation is bad; vessels should have high comming and main hatches taken off whenever weather permits. Always order my captains to take off the hatches whenever the weather permits. Had vessels to India and other distant trades, but never had fire on board any of them.

From Messrs. Thomas Skinner & Co.

1. Never.

3. We have a considerable number of iron ventilators from the deck, and in some cases have carried a wooden trunk along the bottom, connecting it with upright ventilators to the deck in others. We had no ventilation through the coals at all, and all went safe.

4. Register and one third.

5. Both Cardiff and West Hartley.

6. So far as we know only a few days.

7. None except as described in third paragraph. Fire engine.

8. None, as ships and steamers have just gone as safely that had none but deck ventilators as those ventilated through the whole cargo.

B. MASTERS.

Upwards of 100 of the following Paper of Questions were issued to MASTERS of Vessels employed in the Coal Trade.

QUESTIONS TO MASTERS.

1. Has spontaneous combustion, or explosion, ever occurred in any coal-laden vessel under your command?

2. If so, state all the circumstances of each case, as fully as you can, on one of the inclosed forms.

3. Do the owners, or others interested in the safety of the ship or cargo, generally give you any special directions for providing against spontaneous combustion or explosion, or for dealing with fire from these causes should it occur? If so, state them, noting any distinctions in them for fine or stormy weather.

4. In the absence of any instructions, what system of ventilation, if any, do you adopt in the holds of coal-laden vessels under your command? State at the same time the materials of which the ships to which you refer are constructed.

5. Is the ventilation constant, or, if not, at what intervals, and under what circumstances?

6. Is it customary to fill the hold completely up to the square of the hatchways, or to allow a space to remain between the surface of the cargo and the deck beams?

7. Do you test the temperature of the hold during the voyage, and, if so, how, and how often?

8. What means or appliances are usually at your command on board for testing temperature?

9. Does your experience lead you to the opinion that coal has a tendency to "heat" in the tropics?

10. What precautionary rules against explosion do you lay down as to the use of lights?

11. What kinds of coal have you generally carried? State whether small or lump, the names of the collieries, which seams, and whether double or single screened.

12. Are there any special kinds of coal exported that you have found to be more liable to spontaneous combustion than others? If so, describe them.

13. What do you gather to be the general impression among shipmasters as to the provisions made on board coal-carrying ships for the prevention of spontaneous combustion or explosion?

14. Have you any remarks to make, or suggestions to offer, to the Commission on the subject of their inquiry?

Please write "*Confidential*" against any of your answers that you desire to be so treated.

The following are some of the Replies received to these Questions.

From Captain P. T. van Overklift.

"Anna of Rotterdam." (*See* p. 93.)

1. Yes; "Anna," of Rotterdam, 969 tons register. My ship was twice in danger from spontaneous combustion of a coal cargo.

3. Nothing further than that I must ventilate the cargo as ordered by the surveyor for French Lloyds. I received a certificate that the cargo was properly ventilated.

4. Sometimes I have not ventilated, but lately I put wooden pipes in the hatchways; last voyage I had in addition wooden pipes along the keelson.

5. Always acting.

6. Lower hold completely filled except forward and aft. The 'tween decks were only partly filled, a space of two feet being left all over the coals up to the deck.

7. Yes, frequently during the voyage, sometimes twice a day.

8. By thermometer, but unfortunately it would only indicate as high as 110° Fahrenheit.

9. No, or but very slightly.

10. I use a miner's safety lamp, also wind sails to remove the gas emitted by the coal.

11. Always steam coals from Newcastle or Cardiff, once patent fuel from Cardiff.

12. I do not know.

13. Captains are most afraid of explosions, they have usually great faith in the efficacy of pipes in the cargo.

14. All depends on the quality of the coal. I would suggest that coal liable to ignite spontaneously should not be exported for long voyages.

From Captain James Finlay.

"Alfred of Belfast." (*See* p. 85.)

1. Neither has happened in any vessel I have commanded. Spontaneous combustion occurred on board a ship in which I was chief officer.

3. Messrs. I. and T. Sinclair of Belfast and W. P. Sinclair & Co. Liverpool, owners of the ships I have sailed in as master from 1852 to 1872, take care to have their ships well ventilated with air shafts through the coals whilst loading, and instruct the masters to keep the hatches open at all times during the voyage when safe to do so. Their ships generally took coals to the East Indies on the outward voyage, and there never was a case of spontaneous combustion known.

4. Their ships constructed some of wood and some of iron.

5. Constant unless in bad weather, when the hatches had to be put on, then we generally managed to have some deck ventilation open.

6. A space is generally left under the beams, no ship could carry the hold quite full of coals.

7. No, unless by personal feeling; I generally visited the hold once every day. Officers were often in the hold when on duty.

8. Common thermometer, of which there are generally one or two on board every ship.

9. I have found steam arise from the coal in the tropics, I think from the increased temperature of the atmosphere.

10. I had the lamps closed and locked before being taken into the hold, as a preventative against fire.

11. Both large and small mixed. Most of the cargoes I have taken from Birkenhead, Brymbo and Welsh Hartley coals; one cargo shipped there was brought from Merthyr, South Wales. I have also taken three large cargoes from Sunderland to the East Indies, all Londonderry West Hartley coal.

12. The Merthyr South Wales coals were the most *suspicious-looking* cargo I ever had from Birkenhead to Singapore, four months passage, in 1869, but kept cool all the way.

13. All I have consulted agree with me that if the coals are shipped in a dry state and ventilated on board, and the hatches kept open at sea, there is little danger of spontaneous combustion.

14. Captain W. Pirie, of 12, North John Street, Liverpool, who has been overlooker for the ships I have sailed, and others belonging to the same owners, could give information on this subject and the names of the collieries from whence the ships were loaded.

From Captain F. G. Fry, Liverpool.

'Admiral Lyons," "Glenlyon," "Hannah Law.", (*See* p. 86.)

1. Yes.

3. The owners of the ships I have commanded always gave particular instructions to give free ventilation to the cargo by keeping off the hatches when practicable, and during stormy weather to keep the shafts up each hatchway open. The free use of windsails and a careful register of the temperature of the hold by using the thermometer each day at noon, lowering it down the shafting of each hatch to determine the temperature of each portion of the cargo.

4. By keeping off all hatches during fine weather and keeping open all ventilation possible during stormy. Constructed of wood of the pine species.

5. Yes, when a shaft is used at each hatch and sufficiently high above the deck to be kept open during stormy weather, and fitted with a cowl on the top to keep out rain.

6. It is customary to fill the ship up to the deck in the middle section in order to keep the centre of gravity high up to make the ship easy, but after a few days at sea the cargo settles sufficient to make a clear space between cargo and deck beams. Hatchways are mostly filled up to the square when a ship has finished, but usually trimmed down afterwards for purpose of ventilation.

7. Yes; each day at noon down each shaft in the hatches.

8. Copper-framed thermometers protected by wire.

9. Yes; more especially in calm weather when there is but little motion, or wet weather when the hatches have to be kept on.

10. By using the safety lantern.

11. Howard's West Hartley, Westminster, Brymbo steam, Laird's Welsh Hartley, Powell, Duffyrn steam, Aberdare steam, all double screened and moderately lumpy.

12. Howard's West Hartley steam and Westminster Brymbo steam more dangerous if shipped newly wrought or wet with rain.

13. That they would like to have the means to admit a large body of water into the hold in case of fire or be provided with an apparatus to inject a gas into the hold to extinguish fire.

14. Yes, to advocate the adoption of a sea valve to admit water in such a volume that it would speedily flood the hold in case of fire, also the loading of coals by hand in lieu of the tips. The providing of every ship with a fire extinguisher and means to inject an extinguishing gas into the hold in sufficient quantity to permeate the whole cargo.

From Captain William Buchanan.

"Royal Family." (*See* p. 87.)

1. No; in one instance the coals became very much heated.

3. The owners gave me no special instructions, as they approved of my method, but usually enjoined caution.

4. I usually laid a strong platform, planks nailed roughly close together, fore and aft the hold to about 10 feet from each end, where I placed ventilators. Between fore and main masts I placed a jelesie ventilator athwart ship leading into lower air ports, with an upright ventilator of same description amidship leading up to main deck. The ships to which I refer were two and three decked ones constructed of wood.

5. Ventilation constant.

6. Always filled full up amidships and left any space in the ends.

7. About once a week tested by driving down iron rods in each hatchway.

8. Carried bars of iron for the purpose.

9. Yes.

10. Always used closed-in lights under deck (with any cargo).

11. Welsh steam coal. Names of colleries unknown, shipped from Cardiff and Birkenhead, single screened.

13. That the open-ended ventilators in hatches are not only much crushed in loading, but are, in the event of ship encountering heavy weather, channels for the entrance of water, which in my opinion is the primary cause of all spontaneous combusion of coals.

14. In large vessels I would recommend the open-ended platform; in small vessels iron bell-mouthed ventilators fixed on deck near the hatchways to carry off the foul air and gas.

From Captain G. Symons, Swansea.

"Serena." (*See* p. 89.)

1. Yes.

3. No special directions are given, but masters are left to their own discretion.

4. The cargo is separated in three or four compartments by platform and double longitudinal deals on their edges fore and aft each side of stanchions the whole length of hold.

5. Constant.

6. According to the weight of coal, in some cases the hold is chock full.

7. Yes, as often as possible in fine weather.

8. Thermometer.

9. Yes.

10. Carrying lights in lanterns.

11. Smelting coal, generally small unscreened.

12. The largest proportion of coal sent to Chili is smelting coal; out of 24 voyages to Chili I have carried smelting coal 23 times.

13. Shipmasters differ very much with regard to this question.

14. In my opinion smelting coal should be stowed in as many separate compartments as possible.

From Captain J. Galloway.

"Malabar." (*See* p. 89.)

1. Yes.

2. Have done so.

3. Nothing further than to see the ventilators carefully put in and to keep hatches off whenever weather would permit.

4. Have replied to this in statement as to the "Malabar."

5. Constant.

6. Necessarily there is a space between top of cargo and the deck beams, as no ship can carry herself full to the square of the hatchways.

7. On some voyages not at all, and on others daily.
8. An ordinary thermometer.
9. No.
10. None.
11. Generally called steam coal, both Scotch and English, the former Watsons; Hartley and latter.
12. Cannot specify as to this question.
13. Have never heard any captains complain of insufficient means or provisions, so far as known, being on board.
14. Never to allow coals to be loaded in a wet condition.

From Captain Wm. Kennedy.

"L'Agouhanna." (*See* p. 89.)

1. Yes; once.
3. None.
4. Lay ventilators alongside keelson on both sides, also down each hatch, each one entering into fore and aft ventilators in ship's bottom, each hatch ventilator being 2 feet above coomings; then 6 feet above keelson ventilators place two ventilators (16 inches square) fore and aft, the ends in peak clear of coal; 18 inches under beams place two ventilators right fore and aft, ends clear in the peak; thwartship ventilators into each of the fore and aft ventilators at each hatch entering into upright ventilators.
5. Constant.
6. The coal from fore part of after hatch to about 13 feet before fore part of main hatch, 2 feet from lower part of deck beams, tapering in each end to about 5 feet from lower part of deck beam.
7. Once a week, by a thermometer being lowered down upright ventilator.
8. Thermometer.
9. Find more heat in wake of hatchways in from 30° to 40° W., or ditto south, than in tropics.
10. None allowed below decks.
11. North Wales and Cardiff coals.
12. Cannot say.
13. Consider ventilation best preventative, but should fire occur I believe ventilators assist the burning; in 1872 loaded 1,900 tons coal in Glasgow, "Loconada;" no ventilators and no signs of heating. Consider coal should not be shipped during wet weather.

From Captain C. S. Caird, Greenock.

"Arracan." (*See* p. 92.)

1. Yes.
3. I have been left to my own judgment from my owners; always advised not to ventilate by the coal shippers in the Tyne.
4. "Arabia," three upright ventilators. The fore hatch one was burned 3 feet at foot when discharged at Bombay; no other fire. Coals very hot in the hatches among the small in several vessels. I have found this small coal to be almost unbearable discharging with and without ventilators.
6. It is advisable to fill a ship amidships up to the deck beams, leave all open space in the ends for to ease the vessel.
7. Only by going below and feeling above blood heat, especially forward, three times a week.
8. Thermometer.
9 Yes.
10. Never seen nor never used any.
11. Steam coal:—Tyne, Sunderland, Swansea, Cardiff, and Birkenhead loaded?
12. Can't say as all small coals are liable if damp even in bunkers and smiths' heaps.
13. Careless in loading and coals getting wet, trimmers not cautious in protecting ventilation and dividing coal big and small?
14. Have never seen any care taken to keep coal dry while loading in the north or Cardiff. Inspectors are much wanted to look after ventilation and stowage.

From Captain John Frostick.

"John," (*See* p. 93.)

1. Yes.
5. Constant.
8. None.
9. No.
11. Abbw coal.
12. Some of the South Wales smelting coal are more iable than others.
14. In my opinion coal cargoes when bound on long voyages ought to be shipped dry, and laid upon a platform, say 6 inches high, with an up and down ventilator at each end, which would cause a strong draught under the cargo.

From Captain John Ramsey, South Shields.

"Columbia." (*See* p. 85.)

1. Yes, on one occasion.
3. None.
4. I never ventilated any ship except the one named in the accompanying form. I have had command of both wood and iron ships.
6. The hold was always filled quite up to the square of the main hatch, but with generally a large space left at both ends of the ship.
7. No.
8. I have always had a thermometer on board which I could have used.
9. No, I do not think so.
10. I never allowed naked lights in the hold.
11. Have carried all descriptions of coals from the north country, large and small steam coals and small smithy coals, also Welsh steam coals.
12. No.
13. I think the general opinion among north country captains is that ships are safer when not ventilated.
14. None.

From Captain Henry F. Scott.

1. Three instances of dangerous heating which was effectually subdued by the method described in letter.
3. Never had any directions from owners to provide against the danger, but allowed the expense of ventilators in all but one instance by them; was *once* told to take hatches off occasionally.
4. Horizontal, wooden, square tubes on each side running from end to end of lower hold; well perforated at sides and bottom, and connected to perpendicular tubes from the corners of each hatchway, the latter projecting a foot through hatches, to be able to attach windsails to them to drive air down and through the ventilators.
5. Constant in all except in very stormy weather, when the windsails cannot be used.
6. Few vessels will carry the coals right up to the deck for a long voyage, the stores and water required being heavy. I have always had an average vacancy of about 2 feet under the upper deck when laden entirely with coal. Smaller class of vessels having their cabin and forecastle below the deck, will load nearly full to the deck, but will then be deep, depending much on the kind of coal, light or heavy description.
7. Have always had thermometers kept lowered down the perpendicular tubes and noted the temperature daily in the ship's log book; on finding heat increasing used long probe rods, which are easily forced down to the bottom.
8. As above.
9. Of this I have no doubt from continued testing, especially during long calms; when the vessel has little motion heat increases rapidly. I have paid much attention to this particular effect.
10. Rarely any, when ventilated and the hatches kept off as much as possible. It is nearly impossible to prevent taking lights below or striking matches by seamen.
11. Both large and smithy coal, mostly the former, have few records of names of the collieries; have had both screened, double and single, and unscreened; the latter appear most liable to heat, particularly under the hatches where the dust forms a heap which cannot be ventilated.
12. In my cases "West Hartley" heated quickly, also "Cowpen"; have no record of others which I have carried as to name.
14. Respectfully beg to refer to letters on the subject.

12, Grove Street, Newcastle-on-Tyne,
May 1st, 1875.

Sir,

Actuated by a sincere wish to assist in lessening the chances of calamity by fire at sea, I respectfully address the following observations to you on spontaneous combustion in coal cargoes, and chiefly to submit to your consideration a simple and efficacious method of preventing ignition, and which has in three instances been perfectly successful in ships under my command, the result showing it to be a successful experiment reduced to practice and submitting to your approval whether it might be of sufficient importance to be communicated to the Royal Commission about to investigate the subject referred to. After a few remarks on cause I will describe the method referred to, which for simplicity of construction and ease in carrying out renders it available to all, if disseminated among ship masters and others who may be interested.

From a careful observation I am of opinion that there are four causes. First, from coals which give out gas without the aid of heat, even in a low temperature and which is *greatly assisted* by attrition in shooting them down the hatchways, and those in a vessel with closed hatches frequently explode before leaving port when a light is taken below.

Second.—From coal which does not emit gas at first, but after having been a month or two closed up in a ship's hold in tropical waters a gas is generated in them assisting an increase of heat and which unexpectedly culminates in an explosion (as in the case of the "Belcarreg" and other ships).

Third.—From small, dusty, or smithy coal, lying so compact that it is difficult to ventilate it.

Fourth.—From coals which are shipped in a wet state, say in rainy weather, and if unscreened and small are certain to heat in a short time. In this last description heat increases rapidly towards the last, of which I lately had an unmistakable proof.

In 1852 I took a cargo of coal from Sunderland to Madras without ventilators. After passing the Cape, not having been able to take off hatches for a considerable time owing to bad weather, were alarmed at finding smoke issuing from the cargo, with a strong smell of incipient gas. In this dilemma a panic came over my crew, and they insisted on getting the boats out and preparing to leave the ship. Now as danger and necessity often sharpens the wits, after looking at things in all its bearings I determined to try and save ship and life likewise. After a little trouble in getting my men to second me in my plans we went to work.

Happening to have on board some rod iron I roughly pointed a few of the bars and drove them down into the cargo in different directions, allowing them to remain awhile we drew them out, feeling them all their length with the hand, marking the hottest parts with chalk. By driving them down in all directions from the main hatchway I found that the heat was all in one place, forming a nucleus of about 10 feet in the lower hold and directly under the hatchway, the bars driven diagonally through the coal coming out quite cool. I then got four studding-sail booms roughly squared, and knocking down bulkheads and part of bulwarks to procure boards, we made a trunk about 16 feet long, 2½ feet square at the upper end and 3½ feet at the lower, in form of a square *cone*. We then dug down as far as we could, and placed the *large end* of the cone in the hole with a man inside, who dug out the coal from under it, driving the cone down from the top as the hot coals were sent up in buckets. After getting down about 7 feet we came upon the coal so hot that the man at the bottom could only remain a short time, and had to be replaced at short intervals owing to the great heat and smoke and putting his feet into wooden boxes which we made to save from burning them. We now found that as fast as the coal was cleared from the bottom, the trunk crept down *without forcing*, owing to its conical shape and the rolling of the vessel. In six hours we had it down to the keelson, and by removing each alternate board from the side of the trunk at the hottest part we grubbed out great part of the coal which was smoking, and would not have been long before taking fire. I then rigged a topmast studding sail as a wind-sail, tying the foot of it round the top of the cone, and thus forcing a strong current of air down to the bottom and through the sides where the boards were removed, and in about 24 hours, on going down our pit, we had the inexpressible pleasure of finding the temperature little more than milk warm, and by continuing the use of the windsail all heat and smoke disappeared, and ignition was prevented just in time.

On two subsequent occasions I have repeated the process, and always found it successful. I have invariably found the heating to commence right under the hatchways, but chiefly the main hatchway, the largest body lying there, and this I account for thus: The coals as they are poured down from the spout or bottoms of waggons perpendicularly, form an increasing heap of small and dust coal, as the large coal roll away down the sides of the pyramid thus formed, leaving a mass of small coal imbedded in dust in the centre of the hold, the large coal as they are trimmed to other parts ventilating themselves, while the heat is invariably generated in the undisturbed pyramid in the centre, and which will gradually extend to the surrounding parts if not prevented in time by the process above described. I may add that I have had to cut the cone into several parts, joining one on to the other below the deck, when the state of the weather and sea obliged us to keep hatches battened down, so that we found no difficulty in getting a cone of 17 feet down, even with closed hatches, and thus saved ship and cargo.

I will now state a case which may be said to come under cause second.

In 1858 I took a cargo of coal out to Melbourne for gasworks, properly ventilated on my own plans, frequently attaching wind-sails to the upright tubes and forcing air all through the cargo. The barque "Lizzie Scott" sailed with me at the same time, and with the same kind of coal for Melbourne also, but *without ventilators*. My cargo heated a little, but I kept it down with the help of the wind-sails, and discharged in good order. The "Lizzie Scott" arrived at Melbourne apparently all right, but on discharging they found to their surprise that the cargo got quite hot as they worked down, and that the two hold beams of the part nearest the main hatch were burnt away, all except the ends. On getting further down they found nothing but coke, and that the keelson to the extent of about 20 feet had entirely disappeared, leaving nothing but the bolts sticking up, and that a corresponding area of the bottom ceiling was burnt away and charred an inch or so into the floor timbers. All this I saw myself; but the strangest thing was that there was scarcely any smoke, and before breaking bulk on arrival, they had seen no sign of smoke in any part of the vessel and never suspected fire, so completely had it consumed its own smoke. I attribute this case to the want of ventilators.

By the use of wind-sails attached to the upright tubes of ventilators I have frequently reduced the heat 15 and 30 degrees in as many hours in a stiff breeze, always keeping a couple of small thermometers lowered down the tubes, registering the increase or decrease of heat daily in the log. After heat has attained to a certain point the large coal crumble to fragments, accelerating the escape of gas as it is evolved by the increasing heat, thus augmenting the danger of explosion, and when it is discovered that the coal in the lower part of the cargo has become heated to a dangerous point it is useless to deluge it with water, the effect being only to form an impenetrable crust over the heated part, through which the water cannot descend, but finds its way down the sides where it is useless for the purpose.

In conclusion I may say the most important points are to use the probe rods frequently, and then if danger threatens not to put off too long, but use the means to subdue the heat before it gets beyond the power of control, and this I affirm can be done in most cases by adopting the foregoing method. The materials required cost but little, and to condense the whole into a few words, let a ship about to proceed on a long voyage with coal be provided with a few ¾-inch rods of iron, a moderate quantity of rough inch boards, some extra nails and (to save studding-sail booms) a few poles with those, and a knowledge of the construction of the cone, which is very simple, the watchful commander is prepared to checkmate a merciless enemy, insidious at first, but terrible at last.

I am, &c.
(Signed) Henry F. Scott.

R. B. Peverley, Esq., Secretary,
Chamber of Commerce, South Shields.

12, Grove Street, Newcastle-on-Tyne,
28th May 1875.

Sir,

I beg to return the circular of questions relating to spontaneous combustion in coal-laden ships which I have had the honour to receive.

As the questions therein appear chiefly to apply to cases of *actual fire* I am not in a position to attach the answers in direct form, owing to never having had a vessel under my command actually on fire, and having in my cases of dangerous heating always succeeded in preventing ignition in time.

My exertions have been directed chiefly to the means of prevention and subduing of heating before it got beyond control, for if allowed to heat to a certain degree explosion or combustion is certain to ensue if means are not used to stop or check it in time, and this I have proved can be effected with comparative ease by the method which I have in three instances adopted and which in each case succeeded to my utmost wish. I lately addressed a letter to the Secretary of the South Shields Chamber of Commerce describing the method, also describing how effectual it proved, and I am informed by that gentleman that he had kindly forwarded the letter to you, and to which I beg respectfully to refer you for description.

Taking a deep interest in the subject, I beg with deference to submit to the consideration of the Royal Commission the method referred to.

In the letter above-mentioned I described my first case, and now will as briefly as possible give the other two.

In June 1862 I sailed from Sunderland in command of the ship "Areta," wooden ship, of 678 tons register, laden with 700 tons of "Hartley's" large coal, single screened, and about 200 tons glass on the top of the coal, bound to Shanghai, the coal having wooden ventilators. After being three months at sea, having previously found by the thermometers in the tubes that the coal was heating, I found by the probe rods that the heat under the hatchways in the lower hold (where it invariably generates) that fire was imminent before I could reach port (I was then entering the Pacific). Being prepared with materials I lost no time in making the cones, as described in the letter referred to, and sunk them down to the bottom of the hold, bringing up the coal dangerously hot, the thermometer buried in them showing 180°, and the heat had been increasing rapidly for the few days previous. I put a cone down all three hatchways where I found the greatest heat, and by attaching large windsails to the mouths of them the heat was reduced so quickly that in a few days it subsided to 100°. On arriving at Shanghai it had receded to 90°, but in the bottom round the cones I found on discharging the coal had the appearance of semi-melted bitumen, showing it had been subjected to great heat. Those coals were partly shipped in a wet state, and although they were pierced fore and aft with ventilating tubes I am convinced that actual ignition would have taken place in a short time if the means described had not been resorted to. * * *

"Touching explosions, I am convinced that if the hatches of a coal-laden ship are kept off whenever the weather permits, and if the ship be provided with properly arranged ventilators on a principle I would be glad to explain (and they are anything but costly), such disasters would rarely occur. Hatches can generally be kept off night and day in the trade winds, and the ventilation be made *continuous* the whole way through the longest stage of the voyage and where the heating is most to be apprehended, for undoubtedly it is between Cancer and Capricorn that the greatest danger of heating and emission of inflammable gas exists, but coals shipped wet are the greatest danger of all.

"In all cases of heating under my notice I have found that *with the exception of the coal being wet all through* the first indication was found immediately under the hatchways, particularly the main one where the greatest body is, and from experience have the greatest confidence in the efficacy of the cone method in preventing actual combustion from taking place. Moreover, the extreme simplicity of the method, and the ease with which it can be carried out, renders it available to those who may be in peril of conflagration in a part of the ocean where there is no escape except the doubtful one of boats.

In conclusion, I have some misgivings that addressing you to such length may be deemed informal, and not in accordance with the intention of the Royal Commission to elicit information on the subject, but as the questions in the form appear to apply only to cases of actual fire I have ventured to submit the foregoing experiences in the present form, confining my remarks to *prevention* of actual ignition, and actuated by a sincere desire to contribute towards lessening the number of terrible casualties of which the writer has for many years been in dread.

I am, &c.

J. M. Carmichael, Esq., Secretary. HENRY F. SCOTT.

From Captain A. PEARE, Swansea.

'Henry Bath,' "Alpha." (*See* p. 90.)

1. Coals have heated and cooled again on the voyage.

3. Instructed to give all possible ventilation by keeping the booby hatch off at all times the weather will permit.

4. By running planks fore and aft on each side of the stanchions from keelson to the deck. Ships all of wood.

5. When hatches are closed, the iron ventilators through the decks are sufficient.

6. The hold is generally filled up at the main hatchway, but settle down after being a short time at sea.

7. By lowering a thermometer occasionally down to the keelson, and by running a long rod of iron as far as possible into the cargo.

8. Thermometer.

9. Yes.

10. None required with smelting coals.

11. Smelting coal, which is oftener small than otherwise. Broadoak, Techan, Mynydd y Bach.

13. Masters appear quite satisfied with our system of ventilation or separation.

14. That shippers should be particular about the class of coal they ship for long voyages, and colliery proprietors should ship clean coal. From the year 1860 to 1867 I was in command of several ships carrying coal from Swansea to West Coast of South America. I adopted the system of separation by running planks fore and aft the ship upon each side of the stanchions, from the keelson to the upper deck beams, and never had any case of spontaneous combustion or explosion, and from 1867 up to the present time I have superintended the loading of at least 150 ships with coal, principally smelting coal, and have always adopted the same system of separation, and have only had the two cases of spontaneous combustion mentioned in the paper. The "Henry Bath" put into Port Stanley and discharged part of her cargo. The coals were much heated, but no fire. They turned the coals over in the hold, and took the remainder they had discharged in again and proceeded on their voyage. The "Alpha" put back to Port Stanley and discharged part, and found the inside planking and several of the floors charred and burnt; she was partially repaired and took in her coals again and proceeded on her voyage. I attribute the heating of the coal to its being very small and very wet when shipped. I adopt the same system of separation with steam coal, and find it answer well, and vessels having iron ventilators through their decks will always be clear of gas and very little fear of explosion. I think the great number of casualties to ships loaded with coal in the last two years may be attributed to the high price of coal, and a great many of the coal proprietors have not been particular about the quality of the coal shipped; and if shippers and colliery proprietors only act conscientiously in regard to the coal they ship, and ordinary care used in the loading and ventilation, coal ought to be a safe cargo. I have always found the under-mentioned coal quite safe with my system of ventilation or separation. At Swansea the Broadoak, Techan, Mynydd y Bach,—the "Alpha" and "Henry Bath" excepted,—Rhyding; Nixons and Powell Duffryns (steam); at Shields the Tanfield Moor; at Liverpool the Ornell. I consider the system of putting a ventilator at each hatchway when loaded with smelting coal of much more harm than use, with steam coal it may be of some use, but as a rule they are either broken or filled with coal before the ship is loaded; the separation with boards or planks is expensive, but safest.

From CAPTAIN of the "NORTHBROOK," forwarded by Messrs. Adamson & Ronaldson.

'Northbrook." (*See* p. 96.)

1. No, except as stated in enclosure.

3. It is not usual for me to receive any special instructions except from Captain Muscatt (ships husband).

4. Establish a free current of air through the hold. Iron wood.

5. Constant, except in cases of very bad weather.

6. No, spaces are always left for a free current of air.

7. Occasionally.

8. Thermometers.

9. No.

10. No naked lights below, and all lights extinguished at 9 p.m. except those absolutely necessary.

11. Not known.

12. I cannot tell.

13. I don't know.

14. Nothing more than a complete system of ventilation.

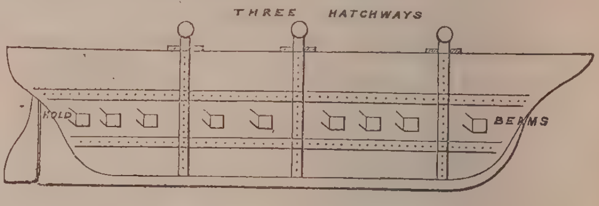
From Captain WM. MURCH, Newcastle-on-Tyne.

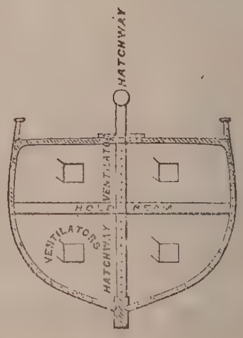
1. Spontaneous combustion has taken place on board of a steamer I was chief officer in, by the overheating of the coal in bunker (Midridge coal), shipped at Hartlepool; it was caused by the coal laying against the heated bulkhead of engine room.

2. There was no damage done in this instance as it was in deck bunker, and with a copius supply of water was soon extinguished,

* * * * *

4. The following diagram will show the system I would adopt either in wood or iron ships:—





This shows four trunkways fore and aft the hold, say 8 inches square, perforated with auger holes at every 18 inches, connected with a trunkway in each hatchway, the same protruding 6 feet above the hatch to keep the water out in bad weather. This was adopted on the last voyage I was out to India and found it answer well.

5. The ventilation would be constant because the tops of ventilators in hatchways could be fitted with their heads to slew to leeward, by that means preventing any seas breaking into them, and by that means keeping up a constant circulation of air through the coal. The present system generally used is to take off the hatches in fine weather, which only allows the surface heat and gas to escape, and I have been a fortnight rounding the Cape of Good Hope in winter when it would not have been prudent to have taken a hatch off.

6. It is customary to fill up square with the hatchway, but there is generally a space below the deck, the height of the deck beams.

7. I never tested the heat of a ship's hold, although in the tropics when the hatches have been taken off it was found like a moderately-heated oven, more especially in iron ships with rice cargoes, as such sweats tremendous, therefore the same system of ventilation applys to them.

8. I have seldom seen a thermometer on board of ships, except those connected with barometer.

9. I have great confidence in saying that coals has a great tendency to heat in the tropics. Some years ago I was in Havana, where I saw some hundreds of tons of coal laying in a heap 20 feet deep take fire by getting wet and being exposed to the sun's rays, although exposed to the open air.

10. Where there is any suspicion of gas don't use any lights whatever below.

11. Both steam and gas, mostly steam.

12. Most kinds of coal are liable to spontaneous combustion if shipped in a wet state and destined for a long voyage.

13. I have spoken to many shipmasters upon the subject of spontaneous combustion, and found many to agree with me that coal ships on long passages are like coal mines, and ought to be treated the same in respect to ventilation, and I may say the same applys to all ships loaded with inflammable material.

14. Remarks. 1. All sailing ships bound south of the equator or continent of America or West Indies to be ventilated through the coal as proposed. 2. All coal coming from the collieries to be brought in covered waggons to ships. 3. When not teaming coal on board ship, hatches to be kept on, preventing any water getting into coal. I think if those simple, yet efficient, means were used, and have a proper authority to see it was done, we would seldom hear of such lamentable cases as the ships "Euxine" and "Arracan," and I have no hesitation in saying many more that have never been again heard of, besides saving much capital.

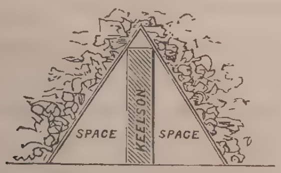
From Captain James Muir, Liverpool.

1. No.

2. Never occurred with me.

3. Yes; by ventilation as a preventative. No; as regards steps to be taken in case of fire.

4. Usual method of ventilation adopted by me, and approved by owners, as follows:—Fore and aft the keelson on each side by means of wood laid from top of keelson to the floor, angled so as to give good air space and view. In addition to this an upright shaft in each hatch from floor to upper part of hatch combings, with sufficient span at bottom to cover ventilation of keelson. Fore and after hatches kept off whenever weather admits. Wooden ships, colonial build.



5. Constant but sluggish in calm weather and smooth sea.

6. Fore and after hatches generally clear. Main hatch often filled up to top of combings. There ought to be a free air space fore and aft under main deck.

7. Yes, by thermometer lowered down the ventilation shaft. Twice a day.

8. Every ship coal laden should have thermometers on board and the captain be instructed to use them.

9. No, I found in very hot weather, that the temperature of the hold at foot of shaft was lower than the temperature in the shade on deck.

10. None. Except for the first few days after the ship was laden. Hatches should not be put on immediately.

11. Steam and gas, generally lump, cannot name colliery or seam, steam coal usually double screened, have carried in all 14 cargoes. Cardiff, Tyne, and Liverpool.

12. I have been informed by steathmen in Cardiff and the Tyne that some classes of coal are more dangerous than others, but cannot say from own experience.

13. The majority are in favour of ample ventilation, and many think with myself that sufficient care is not taken in ventilating the ships or in keeping off the hatches. Cases have been mentioned to me where the hatches have not been removed for the entire passage.

From Captain Cloake, Cardiff.

1. On two occasions an explosion of gas occurred, caused on both occasions by engineers taking naked lights in the after compartment.

3. Many owners give instructions to attend to ventilation of hold by opening hatchways when weather allows such to be done, also by putting ventilators down in holds. So far as my own instructions went I had no special orders, and my experience was greater than my owner's, and he would not have objected to any means being taken to ensure safety.

4. I had 25 years' experience in command, 12 years of that time in steam, and I on all occasions when opportunity occured opened the hatchways, two if possible, one for down and other for upcast. I have heard of instances of air being forced by pumps into the hold, thus causing circulation. Above explosions were in steamers built of iron.

5. In steamers I commanded, being for the fruit trade, we had proper ventilators fitted; in this case the ventilation was pretty constant, but where only hatches were available it depended on the weather and also to attention of the officers in causing the hatches to be opened.

6. With Welsh coal the holds are very rarely full, being often much space left, especially at ends of the ship; the bodies of the hold or in the neighbourhood of the hatchways are often filled up to deck, but the large Welsh coal generally leaves vacancies near the deck. One great stoppage of ventilation is caused by trimmers to save labour having at finish of loading to cram the hatchways very full, filling up to top of combings, packing same preventing gases escaping freely.

9. Coal in my opinion has a greater tendency to heat in the tropics than in the cooler latitudes.

10. For going into holds I have always carried safety lamps, also for going into funnel of steamers and watertight compartment; at same time open lights are mostly used in the cabins and forecastles.

11. I have loaded all kinds of coal, mostly Welsh coal, at times the coal has been double sometimes single screened, and also carried small coal as cargo; both explosions occurred with large Welsh coal.

12. We have some coals, both in the north and Wales containing much more gas than others; but regarding spontaneous combustion, in my opinion this depends on the state the coal is shipped in, and also whether it is comprised of much small coal in the cargo; again, some Welsh coal after being wet and then shipped falls all to dust, and this would in my opinion foster heat.

From Captain Beldrum, Greenock.

1. No.

3. None but to see the ships ventilated in the usual manner.

4. An air shaft running fore and aft each side of the keelson; second, another running same way half way up in the lower hold communicating with the air shafts down each hatch. Both wood and iron.

5. Constant at all times, but freer in stormy weather.

6. Coals should not touch the upper deck and a passage left round the wings 'twixt decks and lower hold.

7. Have never done so.

8. None but the common thermometer.

9. I am of opinion that it does.

10. Never permitting any below.

11. Cardiff steam coal, coal shipped from Birkenhead to Bombay and from Clyde to Bombay.

12. Am not prepared to answer this question, but fancy those from the Tyne the least safe.

13. Insufficient ventilation and putting on the hatches too soon after being loaded.

14. I am also of opinion that were the precautions generally adopted that I have stated in answer to paragraph 4 and the cargo lowered into the hold by hand instead of from "tips" or "large steam cranes" as is usually the case, fewer losses would occur from fire. I would also add that no ship intended to go round either Cape of Good Hope or the Horn ought to be allowed to take in coals otherwise than by basket or wheelbarrow lowered into the hold; when from tips or steam cranes they lay in solid mass under the main hatch, where fire usually first breaks out, the ventilation either partially or altogether destroyed, just sufficient to fan the flame but not enough to allow the foul gases to escape. In my opinion ships would be safer without any ventilation than it in an imperfect state.

From Captain JOHN GIBBS, Birkenhead.

1. No.

3. Only to see carefully to the proper ventilating of the cargo during the course of loading, and this is effected by laying ventilators fore and aft along each side of the keelson, and the same on each side of the lower hold, 5 feet under the beams, all carried out to the ends of the ship; these are all connected with large up and down ventilators in all the hatchways. I have commanded colonial-built vessels of birch, herekmatack, pitch pine.

5. The ventilation is constant.

6. The main hatch is frequently so filled, but should not be.

7. Occasionally by means of a thermometer suspended in hatch ventilator.

8. Thermometers.

9. Becalmed, and more particularly during rains. I am of that opinion it does.

10. That none are used, except in safety lanterns.

11. The North Wales steam coal, as it is produced from the collieries, mostly Bryn Mally and Tron, Brymbo, Broughton.

12. In my experience none more liable than others, but undoubtedly there are some.

13. That the foregoing amount of ventilation generally introduced on board coal-laden ships, if fairly distributed about the cargo, may be looked upon as the greatest safeguard against spontaneous combustion or explosion, but this must be followed up by the constant attention of those on board to the keeping open of the hatches on every available occasion, at the same time keeping the coal dry. These are precautions I have had rigidly carried out during my 13 voyages with coal, and one with patent fuel to India, and in not one instance has the cargo been overheated.

From Captain W. RANKIN, Greenock.

No.

4. Do nothing further than what was provided before the ship sailed, and the ships I commanded were principally wood.

5. Ventilating by the trunk was regular and found satisfactory enough.

6. Surrounding the main and after hatchways the coals have generally been packed close, but there have always been blank spaces in the hold forward and aft.

7. Not usually done by me, but think it highly desirable that it should be so, seeing that thermometers could easily be lowered down the ventilators.

8. Thermometers are generally provided for ships use.

9. It never occurred to me that the tropics have any such effect.

10. Not to admit any light into the hold unless well screened by a lantern.

11. I have no further particulars to give as to the character of the coals carried further than stated in the replies by me as an owner.

12. I believe there are coals more subject to explosion than others, but not being sufficiently acquainted with their characteristics I am unable to give further information.

13. I have never heard any better suggestion made than ventilating by trunks.

14. I may mention that in my early days of sailing in coal-laden ships spontaneous combustion was not thought of, and no provision whatever was made to avoid it.

From Captain H. VELRUNT.

1. Spontaneous combustion took place in the bunkers of a steam transport I was in during the Crimean war.

2. I think it was patent fuel from Swansea, and it ignited on two occasions, steaming for Malta and after arrival.

4. Keep the hatches off where possible. Wood and iron.

6. There should be spaces left at each corner of the hatch to allow the air and gases to escape or a man to get in.

8. Common thermometers.

9. Yes.

12. Salved cargoes of coal or fuel having been under water should not be shipped for long voyages.

13. Not good.

14. Coals should be covered in the waggons if intended for long voyages as a protection from heavy rain. Candles should not be allowed for trimming as they are allowed to lie about and form liquid grease when heated.

C.—STEATHMEN, COAL SHIPPERS, AND OTHERS.

ABOUT 100 OF THE FOLLOWING PAPERS OF QUESTIONS WERE CIRCULATED AMONG STEATHMEN, COAL SHIPPERS, AND OTHERS.

QUESTIONS TO STEATHMEN, COAL SHIPPERS, AND OTHERS IN CHARGE OF COAL BEFORE SHIPMENT.

1. What time usually elapses before coal newly raised from the mine is shipped for exportation? And has there been any change in this respect of late years?

2. Are any precautions taken to shelter coal during wet weather while it is waiting shipment? Does it often occur that it is left in open railway trucks for days together?

3. Is it, or is it not, the custom to ship coal in all weathers?

4. Can you suggest any measure by which coal could be better protected from the weather before shipment without serious inconvenience or expense?

5. State the heights at which the coal usually falls from the wagon into the ship's hold?

Please write "Confidential" against any of your answers which you desire to be so treated.

The following are some of the REPLIES received to these QUESTIONS.

From Messrs. A. FINNIE AND SON, Kilmarnock.

1. Generally shipped same day as raised or following morning.

2. None—seldom for days together.

3. Yes, in all weathers unless prevented by storms.

4. No.

5. From 2 or 3 feet when coal is up to hatchway, to 18 or 20 feet when hold is empty at commencement of loading.

From Messrs. HUGHES AND NEPHEW, Liverpool.

1. Almost all coal from North Wales comes from some distance. Supposing 100 tons are raised from the pit during the day (as at our Cœd Talon Colliery), they are screened, loaded up, and forwarded before the evening, and arrive at Birkenhead in the course of the following day, and are sometimes shipped at once, sometimes not for days.

2. Coal is never conveyed in covered waggons or sheltered during wet weather. It often occurs that coal is left for days together, sometimes for three or four weeeks, in open trucks at Birkenhead before it can be shipped.

3. Coal is shipped in all weathers.

4. Coal might be protected from the weather by tarpaulin coverings, but this would cause inconvenience and expense. To provide other shelter at Birkenhead, say by erecting sheds, would be almost impracticable owing to the immense traffic.

5. As we never load our vessels under the tips, but only by hand barrows, we cannot say from what height coal usually falls from the waggon into the ship's hold.

From Mr. E. C. DOWNING, Cardiff.

1. This varies exceedingly. When the demand is continuously brisk, 12 or 16 hours would be the average time from the mine to the ship's hold; sometimes a delay of many days occurs. In consequence of the greater regularity

of business by increase of steamers, the tendency of late years has been to reduce the interval between the time of working the coal and the shipment.

2. None whatever, except in the case of gas coal, which by some firms is protected by tarpaulins placed over the waggons. The coal is often left in open railway trucks for many days together.

3. It is the custom to ship coal in all weathers by night as well as by day.

4. I think that coal liable to ignite spontaneously, when intended for shipment to distant parts (say where the voyage exceeds three weeks or a month) should be protected from the wet by tarpaulins over the waggons. This precaution should be enforced by some legal enactment, the expense would be trifling. Cardiff steam coal proper will not ignite spontaneously.

5. The mode adopted for shipping coal at Cardiff is this. The coal is emptied from the waggon into a long shoot extending from the tip to the hatchway of the ship. At first the coal is lowered into the hold in a box (arranged with a counterpoise) until a large heap is formed. When the box cannot longer be used the coal falls from the point of the shoot into the hold on the coal, a distance of five or six feet, until the hatchway is filled after which there should be no distance for the coal to fall.

From Messrs. John Pirie & Co., London.

1. This depends on the state of trade, when demand is good the coal is put on board with the least possible delay, often in a few hours. When trade is bad, it has sometimes to wait a market on the bank or in trucks. There has been no change of late years in this respect.

2. No.

Yes, in wet weather this must be so, as there are no sheds at collieries for loaded waggons, and they are exposed during the journey from colliery to place of shipment and there till shipped.

3. Often in wet weather.

4. Only by having trucks covered which is scarcely practicable.

5. Depends where and how shipped, by shoot or drop; a heap is generally allowed to acumulate under hatch so that coal slides down sides of pyramid instead of falling into hold.

From Messrs. Merry and Cuninghame (Limited), Glasgow.

1. From two to ten days; average four to five days. It very seldom occurs that coal has to stand ten days in trucks previous to shipment. The time it has to stand depends very much on the state of trade; when there is a good demand for coal it is not kept standing in trucks very long. Matters in this respect have been much the same for a number of years.

2. No precautions are taken, and it often happens that coal is left open in trucks for several days waiting shipment.

3. It is the custom to ship coal in all weathers.

4. Coal waiting shipment could not be protected from the weather without incurring great expense for erecting sheds, as it has to stand at the pits longer than at the shipping ports because the railway company will not take coal forward until the vessel can get into a crane berth.

5. From three to six feet to deck of vessel, according to size of vessel and state of the tide at time of shipment.

From Messrs. W. S. Partridge & Co., London.

1. We believe districts differ in their mode of acting on this point. At present and for some years very little in North Wales has been put on the bank for shipment. The rule is to put newly-raised coal direct into waggons, and send the waggons by first train to the ship.

2. Not as a rule; they may occasionally get sheltered. Sometimes.

3. Where tips are used it is seldom that they are allowed to stand idle at Birkenhead, where we load a large quantity by hand-barrow; the men won't work in very wet weather.

4. We do not think it possible, as the expense would be too heavy.

5. The height various from two to 25 feet, depending on depth of vessel's hold; but if captain or owner will lower carefully about 100 or 150 tons, a mound will be formed under main hatch, and the fall of the coal will be five to seven or eight feet. The longer drop would not be for more than the first 40 tons, as the mound would be rising. Captains do not like the extra expense of lowering.

From Mr. John Traill, Cardiff.

1. When trade is regular, and the supply of shipping sufficient, much South Wales coal is shipped in 24 to 36 hours after being raised. No work is done during the 24 hours of Sunday. The increase in the number of steamships which require quick despatch, improved shipping facilities, and the extension of railway transport, have much tended to hasten shipment of late years.

2. None, except rarely in the case of small consignments of gas coal. It does often occur; sometimes it is left for weeks. All our trucks are open.

3. It is.

4. I think I ought here to premise that many kinds of South Wales coal and all our good steam coals are not liable to spontaneous combustion. With regard to the descriptions so liable, I believe that only a small proportion is sent to distant ports, most of it going for home consumption. Though it would be very desirable that such coal should be protected from rain by tarpaulins, when intended to remain say a month in a vessel's hold. This measure would entail considerable if not serious inconvenience and expense.

5. The mode of shipment usually adopted here prevents the coal falling any great distance; the trucks are brought to the upper extremity of a "shoot," set at an angle of about 40° with the horizon, and of which the lower end reaches to the hatchway. Into this the coal is "tipped," and may if necessary be "screened," or sifted while passing down the shoot, which is furnished with bars for the purpose. The coals then run into a large box with a hinged bottom, by means of which they are lowered into the hold until a heap reaching to within a few feet of the hatchway is formed, when loading proceeds without the box.

From Mr. Joseph Fothergill, Agent to the Cowpen Hartley and Strakers West Hartley Coal Company, Newcastle-on-Tyne.

1. Five to six hours there has been no change.

2. None. No.

3. It is the custom to ship coals in all weathers to keep the mines in regular work.

4. No.

5. The coals fall from the waggons into spouts and thence run into the ship's hold, the end of the spout generally resting on the combings, therefore the fall is to the bottom of the ship until she is run up with cargo.

From Messrs. James Smith & Son, Glasgow.

1. Usually not more than 10 days, no change of lat years.

2. No precautions are taken. It does.

3. It is the custom to ship coal regardless of the weather.

4. We know of no means except that railway companies might provide covered sheds for coal intended to be shipped long voyages, and remove such coal only during dry weather.

5. About five feet above combing of ship's hold. We may add, during some 15 years our firm have shipped a great many cargoes of coal, in no case have we ever heard that combustion has taken place except in one case a ship named the "Workington" loaded by us in June 1874, with 1,640 tons of splint coal was we understand burnt off the River Plate. Her cargo was shipped in very wet weather, and to this cause we ascribe the burning.

From Mr. Rd. Bittaby, Cardiff.

1. Coal is generally sent as fast as it is raised, and is usually tipped within 24 hours; there has been no change in this respect within my knowledge.

2. None. Not as a rule.

3. Yes.

4. As nearly all the coal sent down for shipment rarely stands for any length of time, I do not see that any protection is at all necessary.

5. The drop from the point of the shoot into the hold after the box has been used would be about four feet.

From Mr. John Macdinan, Glasgow.

1. About 48 hours. No change.

2. None. The coals frequently get wet in transit from colliery to port of shipment, and I have known instances of trucks standing loaded for days by ship not being ready

or vessels being in time to load at crane before the ship for which the coals are intended.

3. Customary to ship in all weathers.

4. Only by tarpaulins, but this would be expensive, and tarpaulins would require to be provided by railway companies, as nearly all coals for shipment here are carried in railway trucks, and the trucks after being discharged are probably sent to a different colliery from that at which they previously loaded.

5. Trucks with about 6½ tons of coals are lifted from wharf by steam crane, and lowered on board the vessel to within two to three feet of hatchway, the fall therefore depends on depth of ship's hold and as she loads is decreased.

From Mr. McCullough.

1. Coal is put into waggons and will average about 24 hours ere it is shipped. Has been no material change the last few years. From 5 to 20 years ago, if a colliery was short of waggons, coals would be teemed by, *e.g.*, put in a heap, but this is very expensive.

2. No precautions are taken to shelter coals in waggons during wet weather, and sometimes from various circumstances coals will be left in trucks for several days.

3. Yes, ship in all weathers as a rule.

4. Coals could not be protected from the weather without incurring serious expenses.

5. This varies very much. Some colliers use large iron tubes, which are filled at spout, then lowered into hold; bottom opens by means of a clutch, and the coals are left at bottom of hold, where swing drops are used. Waggon is lowered close to deck; bottom opens; the coals fall into hold of ship; generally in Wales spout reaches within 6 or 8 feet of deck, and from there falls into hold.

From Mr. John Evans, Foreman, to James Thick and Sons.

1. Generally from a week to a fortnight, but in some cases as little as 24 hours. No change since the railway was completed.

2. No precautions are taken to shelter coal, and it is frequently left open for days.

3. Coal is shipped in all weathers.

4. No.

5. From 15 to 20 feet, according to the mode of shipment.

From Messrs. Barnes, Guthrie, & Co., Cardiff.

1. Coal generally shipped within 24 hours after coming out of the mine, seldom, if ever, stacked in this country, excepting in cases of cargoes being relanded; often stored in foreign depôts for many months.

2. No precaution taken. Seldom left in trucks for any length of time, and then only in extreme cases a few days.

3. Coal shipped in all weathers,

4. No.

5. The waggon tips the coal down a shoot about 15 feet long, and from thence the first portion of the cargo runs into an iron box, which is lowered into the hold. The coal falls at an average about 6 feet all throughout an entire cargo.

From Mr. F. E. Stamford, Cardiff.

1. Coal is frequently shipped within 24 hours after it is worked from the mine. Owing to the great pressure for coal during the last three years, the waggons have been emptied sooner than in former years.

2. No.

Yes.

3. It is.

4. No.

5. The coal is tipped out of the waggons down a shoot (of about 15 feet long) to the hatchway of the vessel; the distance from the hatchway to the bottom of the hold is dependent upon the size of the vessel.

From Mr. D. Turner, Peninsular and Oriental Steam Navigation Company, Liverpool.

1. Since the commencement of the late strikes in the coal trades and the consequent short delivery, I find the time elapsed between the dates of leaving the mines and that of shipment is from 24 to 48 hours. I cannot answer the latter question, as my experience does not go back so far.

2. None. Yes.

3. Yes; as required.

4. Certainly not without covered trucks or covered sheds, which would involve expense.

5. Eight to nine feet, the way the sailing vessels are loaded for the Peninsular and Oriental Company.

From Mr. Alexander Dalziel, Cardiff.

1. From 12 hours to three or four days, according to the demand?—No.

2. No, excepting in the cases of certain consumers, who pay a little extra price for having the coals in the best condition?—Yes.

3. It is the custom to ship the coal in all weathers.

4. Coal is too bulky to be covered without great expense and inconvenience.

5. From one to five feet. The coal is lowered by a mechanical contrivance until a cone is formed in the hold.

If this precaution be neglected, then the fall of the coal is great, from 12 to 30 feet; the rule is, however, very fairly adhered to.

From Messrs. John Carr and Son, Newcastle-on-Tyne.

1. From three to 24 hours. No change.

2. None. No.

3. Yes.

4. No. We have been the shippers of several cargoes of steam coals, the vessels carrying which have been reported as lost with all hands, or burnt, but our evidence would only be hearsay. We believe many cargoes of coal are ignited, especially on board of British vessels, through the unfortunate system of keeping the ship's stores above the cargo in the hold, necessitating the use of candles at the exact point where the escaped gas must accumulate.

5. Coal falls from waggon to bunker at top of spout, in general about five feet, and the spout rests upon the combings assisting the fall to the depth of ship's hold, and the quantity of coal shipped.

From Messrs. T. Beynon & Co., Newport, Monmouthshire.

1. Generally speaking, it is raised from the mine, sent down to port, and shipped without delay, if the vessels are ready to receive it.

2. None that I know of. It often occurs that it stands in trucks completely exposed to the weather for some days previous to shipment.

3. Yes.

4. No.

5. In this port (Newport, Monmouthshire), the truck or coal is raised by hydraulic power, and emptied into a shute, the end of which rests or nearly so on the ship's coomings, and the coal when the shute is full is eased into the ship's hold by means of a "wing;" it follows that it is only about the depth of the ship's hold the coal has to fall, and in ships of great depth measures are taken to break this fall.

From H. Cloake.

1. Very often coal when in demand is shipped within a few hours after being worked, or filled into trucks, and I am not aware that any change has been made lately.

2. Coal being filled into trucks open at the top at collieries where worked, and in this manner remains in the open air until shipped, and often for days, sometimes weeks, if the coal does not meet with ready sale or is a coal of inferior class and not much in demand.

3. Coal is shipped in all weathers, and rain must be *very* heavy to prevent or delay shipping.

4. I can suggest no other method than by having covered trucks; in most cases this would not impede or cost more shipping coal, but would delay the loading of trucks at collieries and entail expense there.

5. Coal in Wales is mostly shipped from a shute, which shute goes into the hatchway, therefore the height of the fall of coal would be at commencement loading depth of ship's hold. After coal comes up in centre of ship the fall of coal is almost nil. Some coals are lowered into the hold from boxes until there is a heap formed. This is done to prevent breakage.

D.—PAPER OF QUESTIONS ENCLOSED IN FOREGOING CIRCULARS A. AND B.

THE FOLLOWING IS THE PAPER OF QUESTIONS ENCLOSED TO SHIPOWNERS AND MASTERS, TO BE FILLED UP BY THEM IN THE EVENT OF THEIR HAVING HAD EXPERIENCE OF AN ACTUAL CASE OF SPONTANEOUS COMBUSTION OR EXPLOSION IN COAL-LADEN VESSELS.

1. Name of ship, her class and age, and whether steam or sailing.
2. Date, and port of loading.
3. Destination.
4. Date, and place of combustion or explosion.
5. Of what material the vessel was contructed.
6. Did she make much water, or otherwise?
7. Her (net and gross register) tonnage.
8. No of statute tons of coal shipped.
9. Denomination of coal carried, the name of the colliery, which seam, and whether double or single screened.
10. Name of exporter.
11. Whether the ship's hold was ventilated, and if so, how? And state the material used.
12. In what part of the ship the combustion or explosion took place.
13. How long the coal had been on board.
14. How long the coal had been out of the pits before being put on board.
15. How was the ship loaded, and, if from waggon, from what height did the coal fall into the hold?
16. State of weather at time of loading, and generally during her voyage.
17. Condition, as to moisture, of coal when put on board, and also during the voyage.
18. Was any indication given of the cargo being heated before the fire broke out; if so, how did it show itself, and how long before the fire?
19. Was the temperature of the hold taken during the voyage, and, if so, how, and how often?
20. Was the hold completely filled with coal up to the hatches?
21. During what proportion of the voyage were the hatches open, and did water ever get down, and to what extent?
22. What measures were adopted when there were indications of the cargo heating, and also when the fire broke out?
23. What special appliances, if any, had you on board for the extinction of fire?
24. To what causes do you attribute the spontaneous combustion or explosion in this case?

Please write "confidential" against any of your answers that you desire to be so treated.

PARTICULARS OF CASES OF SPONTANEOUS COMBUSTION SENT IN REPLY TO THE FOREGOING QUESTIONS.

(These cases will also be found in the tabular statements of vessels bound from Great Britain to foreign ports, which suffered from spontaneous combustion. See page .)

"COLUMBIA."

From Captain JOHN RAMSEY (Master) by Mr. THOMAS HENDERSON, Shipowner.

1. "Columbia," 4 years A 1, two years old, sailing ship.
2. Liverpool, January or February 1850.
3. Aden.
4. First off the Cape of Good Hope. When about 90 days out.
5. Wood.
6. No, she was a very tight ship.
7. 517 tons, 633 tons.
8. About 750 tons.
9. I think it was North Welsh coal; cannot give any further information.
10. Coals were for Peninsular and Oriental Company.
11. Ship's hold was ventilated with wood ventilators laid fore and aft, and up and down into the fore main and after hatches.
12. Was first discovered just abaft the fore hatch.
13. About 100 days.
14. Unknown.
15. Entirely from craft.
16. Wet weather whilst loading. Fine-weather passage from leaving Liverpool until fire discovered.
17. Coals wet when taken on board.
18. Yes, for 10 or 15 days before fire broke. Could find a great heat coming up the after hatch.
19. No.
20. Filled up to the main deck in the way of the main hatch, but a space vacant at both ends.
21. Fore hatch was often off, and the after hatch having a booby hatch over it was never closed.
22. So soon as the fire was discovered the carpenter bored a hole through the side, and water was allowed to run in until there was 10 feet in the hold at which height the fire was supposed to be, and when the fire was supposed to be extinguished was pumped out. About a fortnight after the fire again burst out, and the same expedient was used, when 12 feet was run in.
23. None, except the small deck pump.
24. I attribute it to ventilation; up till last year I was constantly employed carrying coals of all descriptions to the East Indies, and on no occasion were the cargoes ventilated, and I had no mishaps.

"ALFRED."

From Captain JAMES FINLAY.

1. "Alfred" of Belfast, sailing ship, classed at Lloyd's five years old.
2. September 1850, London.
3. Valparaiso.
4. January 9th, 1851, off the port of Talcahuano, Chili.
5. Wood spruce, built at St. John's, N.B.
6. A moderate quantity.
7. 1,073 tons register.
8. 1,050 tons, not a full cargo.
9. Transhipped from several collier brigs which brought the coals from the Tyne. Do not know from what colliery, or if screened.
10. Do not know; was bought in the London market by the owner of the ship.
11. Not ventilated.
12. A little before the main hatch, starboard side, about the centre of the body of the coals.
13. Nearly four months.
14. Cannot say, suppose at least eight or ten days. The coal was all weighed into the ship in drafts of two hundredweight each; so any gas among the coals would have ample time to escape.
15. Dropped from the deck into the hold, a height of about 20 feet at first, gradually decreasing.
16. Fine whilst loading, and generally fine during the voyage.
17. Seemed dry all the time; were a small sized coal.
18. First indication was a smell of gas in the hold about 48 hours before the fire broke out, next smoke gradually increasing.
19. No.
20. The hold was only filled to about midway between the 'tween deck beams and the upper deck.
21. The hatches were generally opened during the day in fine weather and closed at night. No water of any consequence got down.
22. A large pit was dug in the coals where the smoke was first seen oozing out, a hole cut in the upper deck above the pit, and water poured down till the pit overflowed; we

found water would not penetrate the coals that way, but flowed over and ran down by the ship's side.

23. None.

24. I attribute this combustion to the small coal being all in one body; the ship not having any 'tween decks to separate the cargo and want of air shafts to carry off the gas generated in the body of the coals.

"MARY SHEPHERD."

From Messrs. Gillespy and Scott, London.

1. "Mary Shepherd," A1 at Lloyd's. 10 years. 4 years old; sailing ship.
2. Autumn, 1852. In London.
3. Shanghai.
4. Spring, 1853. In China Sea.
5. Wood.
6. Believed to be tight.
7. $\frac{550}{629}$ Builder's Register.
8. Record destroyed.
9. Resolven, from Resolven Colliery—handpicked.
10. Thomas Gillespy (now deceased).
11. By wooden trunk alongside keelson, and two or three shafts to hatchways.
12. Believed to have been in the forehold.
13. Four or five months.
14. It was brought by Great Western Railway from Swansea to Bull's Bridge, near Brentford, and conveyed thence by lighters to the West India Dock, London. It was many days on the road much longer than would be the case now.
15. From lighters brought alongside. The coal was lowered into hold by baskets.
16. Wet during loading; do not know the weather during voyage.
17. Exposed to weather in transit from Swansea.
18. Hot decks, &c., for sometime before the fire.
20. Most probably not.
24. It has generally been attributed to the coal having been shipped wet, no other cause has we believe been suggested.

"ADMIRAL LYONS," "GLENLYON," "HANNAH LAW."

From Captain F. G. Fry, Liverpool.

1. "Admiral Lyons," 7 A1; about five years old, sailing ship; I was mate in this ship; "Glenlyon" under my command; "Hannah Law," I was on survey. "Glenlyon," ditto.
2. "Admiral Lyons," Sunderland, June 1861. "Glenlyon," Birkenhead, 1865. "Hannah Law," Birkenhead, 1868. "Glenlyon," Birkenhead, 1868.
3. All. Bombay.
4. "Admiral Lyons," July 1861, about 5° S. 25° W. "Glenlyon," January 1866, Aden. "Hannah Law," January 1869, Bombay Harbour; "Glenlyon" January 1869, Bombay Harbour.
5. All of pine woods.
6. None of them to any extent.
7. "Admiral Lyons," 1133. "Glenlyon," 1440.
8. "Admiral Lyons," about 1,000 tons coal, 400 tons coke; "Glenlyon," 2,050 tons, all coal.
9. "Admiral Lyons," I believe Howard's, West Hartley double screened; "Glenlyon," Westminster, Brymbo double screened; "Hannah Law," I do not know the colliery but shipped from Birkenhead.
10. "Admiral Lyons," do not remember; "Glenlyon," Messrs. Battersly.
11. "Admiral Lyons," two shafts, one each side, 4 feet from the bottom of the ship connected with shafts up each hatch; "Glenlyon," planks on the beams 4 inches apart, ventilation along each side of the keelson connected with a shaft up each hatch.
12. "Admiral Lyons" right under the main hatch about 5 feet from the keelson and close to the ventilator. "Glenlyon," right under the fore hatch, about 5 feet from the keelson and close to the ventilator.

When smoke was first seen issuing from the hold we endeavoured to find the locality of the fire, finding that the temperature in the main hold was the greatest, commenced pouring water down by means of buckets and fire engine, but finding the heat and smoke increasing rapidly, held a council, and decided upon scuttling the ship and admit sufficient water to reach the fire if possible; did so; in the mean time attached large canvas hoses to the main pumps, and kept them going down the main hatch; when the water in the hold had reached 8 feet found steam issuing up the hatchways, plugged the holes up that were made for scuttling. The heat gradually decreased when we dug down the cargo in main hatch and found the fire was entirely extinguished, it having originated about the foot of the ventilation shaft, having burnt it; also a part of the main beam. At times during the rest of the voyage, when we found the temperature of the hold increasing, we poured large quantities of water over the coals which seemed to cool them down; arrived safely in Bombay, in October 1861. "Hannah Law" and "Glenlyon" in each case when called on survey I advised the immediate flooding of the hold which was in each case successful.

13. "Admiral Lyons," 7 weeks; "Glenlyon," 22 weeks; "Hannah Law," 5 months; "Glenlyon," 6 months.
14. I do not know exactly, but I think about two days.
15. "Admiral Lyons" from a short fall about 12 feet. "Glenlyon" tips fell from 15 to 25 feet. "Glenlyon" ditto. "Hannah Law," I think tips, but not certain.
16. "Admiral Lyons," wet. Voyage mostly fine; "Glenlyon," fine loading; fine during voyage; but much calm weather.
17. "Admiral Lyons," damp; steamed a little during voyage; "Glenlyon," dry when shipped; same during voyage; but I noticed much pyrites among the coal.
18. "Admiral Lyons," noticed a little smoke coming up the ventilators a few hours only before the fire; but rapidly increased. "Glenlyon," noticed an increase in the temperature of the hold for several days before the fire.
19. "Admiral Lyons," no; "Glenlyon," every day at noon.
20. Not quite; a free passage was left between the coals and deck fore and aft in each vessel.
21. "Admiral Lyons," fore and aft hatches were kept off always during fine weather, but not the main hatch, as the long boat was stowed on the top of it. "Glenlyon," the hatches were all kept off during fine weather about two thirds of the passage; in each no water got down.
23. In each case a good fire engine, plenty of hose, and two other pumps.

"USK."

From Messrs. T. Beynon & Co., Newport (Mon.).

1. Barque "Usk," lost 1861; built at Newport Mon., age 9 years; sailing vessel, 338 tons register.
2. Swansea, in 1861.
3. Valparaiso and a port.
4. About 200 miles south of Valparaiso.
5. Wood.
6. No, she did not make water.
7. 338.
8. About 450 tons of coal.
9. Smelting coal which was not screened.
10. I think it was Messrs. Henry Bath and Sons, Swansea.
11. In the usual manner, with wooden shafts from each hatchway.
12. It was supposed under the fore hatchway.
13. About 100 days.
14. I think it was shipped almost directly it came from the pit.
15. The ship was loaded from waggons tipped into a shute and allowed to run from thence into the ship's hold.
16. The weather was raining during the loading of the vessel.
17. The coal appeared to be damp when shipped.
18. Only a few hours previously a great heat was felt in the forecastle, and on the fore-hatches being taken off the flames burst up as high as the tops, and the ship was immediately abandoned.
19. I do not think it was.
20. The main hold was completely filled up to the hatches, but the after and fore holds were not.
21. I cannot tell.
22. There was no time to take any measures.
23. None.
24. To the cargo being shipped in a damp state, principally.

"JOANNA," "WANDERER," "ANNIE LAURIE," "MAY QUEEN," "PALMYRA."

From Mr. William Thompson, Uphall.

1. 1 "Joanna". No class. Sailing.
2 "Wanderer." Do. Do.
3 "Annie Laurie." Do. Do.
4 "May Queen." A 1 Do.
5 "Palmyra." A 1 Do.
Nos. 1, 2, 3. August, 1864. Leith.
,, 4. September, 1874. Newcastle.
,, 5. June, 1874. Liverpool.
3. Nos. 1, 2, 3. Quebec.
,, 4. Rangoon.
,, 5. Madras.
4. Nos. 1, 2, 3. October 1864. St. Lawrence.
,, 4. February 1875. Off Madras.
,, 5. October 1874. Do. But Extinguished.
5. All timber.
6. No.
7. No. 1, 555 tons. No. 2, 639 tons. No. 3, 645 tons. No. 4, 1,054 tons. No. 5, 888 tons.
8. No. 1, 442 tons. No. 2, Account lost but under 500 tons. No. 3, 434 tons. No. 4, 1,340 tons. No. 5, 1,206 tons.
9. Nos. 1, 2, 3. Duke of Buccleuch. Unscreened.
,, 4. Cowpen Hartley. Screened.
,, 5. Lancashire Do.
10. Nos. 1, 2, 3, 4. On ship's account.
,, 5. Madras Railway Company.
11. Nos. 1, 2, 3. Not ventilated.
,, 4 and 5. With wood up and down each hatch.
12. Unknown.
13. Nos. 1, 2, 3. About two months.
,, 4 and 5. About four months.
14. Nos. 1, 2, 3. I believe had been stacked at the pit head for some time.
Nos. 4 and 5 fresh drawn.
15. All from waggon by steam crane.
About 20 feet.
16. Unknown.
17. Unknown.
18. By smoke and strong smell of gas.
19. No.
20. In none of them.
21. Orders given to masters to open hatches only in fine weather, and believe this was attended to.
22. Unknown.
24. In cases Nos. 1, 2, 3, the quality of the coal, they were all shipped at the same time. We had carried them for two or three years previously quite safely. We have never shipped any of them since.
Nos. 4 and 5 we cannot explain.

Captain William Riddock, of London, also sent an enclosure relative to these cases.

"LOCHIEL."

From Captain Newton.

1. "Lochiel," of Dundee. Sailing. About nine years old.
2. Off Tayport, 17th September 1864.
3. Calcutta.
4. 4th January 1865. Bay of Bengal.
5. Wood.
6. Tight.
7. 1,501 tons.
8. 1,500 tons.
9. Townhill colliery.
11. Partially ventilated; wood.
12. Amidships; main hatchway.
13. 3½ months.
15. Loaded by tubs from lighters.
16. Very bad while loading; coals thoroughly wet with sea and rain. Moderate during voyage.
17. Very wet.
18. Only 24 hours before. Smoke.
19. No.
20. No.
21. Off every day except a few days before the explosion when crossing Equator.
22. Battened down hatches and made for Galle; escaped in the boats.
23. Ship's pumps.
24. Wetness of the coal.

"HER ROYAL HIGHNESS."

From Messrs. Charles Hill and Sons, Bristol.

1. "Her Royal Highness." A 1 eight years. New ship
2. November 1865; reshipped January 1866. Cardiff.
3. Valparaiso.
4. April 5th, 1866. Latitude 39° S., longitude 54° W. Cargo found to be in a heated state; bore up for Monte Video.
5. Wood.
6. Made some water during bad weather.
7. Gross about 1,280; net register 1,244 tons.
8. 1,804 tons.
9. "Rhonda," No. 3, through and through.
10. Henry Bath and Sons.
11. Ventilated as described in sheet No. 1.
12. The captain, on examining the cargo, found it very much heated under the main hatch, and smoke or steam issuing from it; he forced bars of iron into it as far as possible, and on withdrawing them they were found to be very hot; he feared combustion, and ran the ship back to Monte Video, which was reached in a few days, and where he sold the coals, as the expense of landing and reshipping would have been heavy.
13. Three months.
14. No means of knowing.
15. Loaded in first place from tips, and on reshipping from barrows wheeled over the hatch with a fall of about 24 feet at commencement.
16. The coals were exposed to rain after being discharged; some heavy gales were experienced during the passage.
17. See above.
18. Answered.
19. Temperature frequently taken, and by that means the tendency to combustion was discovered.
20. The cargo was pretty close up in main hatch at starting, but the hold was not full.
21. The hatches were taken off in fine weather, but no water got down.
22. Answered.
23. Answered.
24. This was a new ship and as she was very flat in the floor we placed the platform as high as we thought she would bear it to make her "sea kindly," but we put it too high, and in getting down channel she would not stand up to her canvas, and had to be put back; we discharged a large portion of the coals and took up the platform for a length of 50 or 60 feet, and let the coals run down on to the skin and then reshipped the portion that had been landed; I attribute the accident to the coals having got damp before reshipping, and the platform having been removed from the bottom of the ship so that there was no air or ventilation under the midship portion of the cargo.

"ROYAL FAMILY."

From Captain William Buchanan.

1. "Royal Family," sailing vessel, run five years without being classed, and was then classed five years. Was about six years old at time referred to.
2. Birkenhead, February 1868.
3. Aden.
4. Latitude 35° S., longitude 5° W., 72 days out from Liverpool.
5. Wood.
6. Tight but had encountered very severe weather.
7. Net tonnage register 1,750.
8. About 2,500 tons.
9. Welsh steam, shipped at Birkenhead, single screened.
10. P. and O. Steamship Co.
11. Platform, open ended with jelise ventilator in main hatch of wood, (this ventilator which was all broken below I considered as the cause of heating.)
12. About 14 feet from deck in main hatch.
13. About 80 days.
14. Unknown.
15. Wheeled on board.
16. Rainy weather in loading variable.
17. Damp when put on board, ship tight during voyage.
18. Hatches taken off every opportunily.
19. Once a week driving down iron rods in each hatchway.

20. Main hatch, yes. Ends, no.

21. Water got into the hold only through ventilator in main hatchway.

22. Found that after leaving iron rods in hatches four hours drew them up when they were so hot that they singed the hands. At once dug down to a depth of 14 feet and allowed the air to get at the heated coal.

23. Head and portable force pumps with hose.

24. Ventilator in main hatch being broken below (when loading) while end above remained open, allowing any water which might find an entrance to spread (or lodge) in the coals.

"PERSIA."

From Mr. J. H. Watt, Glasgow.

1. "Persia." Sailing ship, 1,290 tons. Built at Quebec, 1864. Seven years A 1.
2. Sailed from Greenock, 1st September 1868.
3. Bombay.
4. Off Cape of Good Hope, 31st October 1868.
5. Wood.
6. None.
7. Net register 1,290 tons; gross 1,331 tons.
8. 1,830 tons coal.
9. Wishaw coals. Lanarkshire. Single screened.
11. Ventilated with wood fore and aft.
12. Under the poop.
13. About 60 days.
14. Brought direct from the pits to the ship.
15. Loaded with six tons waggon, put on board by engine power, and might fall about 12 feet.
16. Weather was showery.
17. Coal was dry.
18. Heat was experienced in the poop, then in a few days smoke was seen, which increased, until decks were burning; this was followed by a violent explosion, the ship was wrapped in flame and then abandoned.
19. Not that I am aware of.
20. No.
21. I have no knowledge. Ship was tight and no water came on board.
22 Hatches were secured to cut off air, but the final destruction was very rapid.
23. Hand engine with long hose.
24. I cannot give any reason.

"JANET COWAN."

From Mr. James Cuthbert, Greenock.

1. "Janet Cowan," Â, three years sailing.
2. August 1869, Greenock.
3. Bombay.
4. 1st. November 7th, latitude 34° 52′ S., longitude 59° 53′ E.; 2nd. November 21st, latitude 29° 26′ S., longitude 69° 5′ E.; 3rd. December 11th, latitude 12° 58′ N., longitude 70° 16′ E.
5. Iron.
6. She made no water.
7. 1,277 $\frac{70}{100}$.
8. 1,756.
9. Cannot say.

10. J. and R. Young, Buchanan Street, Glasgow charterers.

11. Three ventilators, one in main hatchway, one in quarter hatch, one in ventilator on top of house on deck, of 9-inch deals, with 2½-inch space.

12. In the hatchways.

13. From August till above dates.

14. Cannot say.

15. From Crane by waggon, about 25 feet at the commencement, or about three feet from hatch coomings.

16. Wet for the first 300 tons or so, dry for remainder; fine till within a week of the fire.

17. Seemed to be dry.

18. November 7th, 1869, latitude at noon, 34° 52′ S., longitude 59° 53′ E. Moderate breeze from S.W. at 4 a.m. Saw smoke coming up the quarter hatch, went below and found the hole full of smoke; took off the main hatches and saw the yellow smoke issuing up from among the coals; commenced to get the coals on deck, when up to the rail both sides put them overboard by 11 a.m., was at the 'tween deck beams; the coals were very hot, the smoke yellow and stifling; got on the force pump and played water on the coals in the hatchway, and kept taking them up at the same time; 1 p.m. opened three of the side ports and let the water in as the ship rolled; supposed the fire to be at the bottom. 4 p.m., closed them at 6.30 p.m., no smoke to be seen; kept the pump at work till 7 p.m.; 2 feet 5 inches of water in the pump well; put on all hatches and stopped all ventilation, also main mast-head; covered it as the smoke was coming up it like a funnel during the day, but none at the foremast.

November 8th, lat. 32° 20′ S., long. 61° 50′ E., wind westerly, moderate breeze and cloudy weather, heavy swell from the westward; at daybreak took off the hatches, a great quantity of steam in it and very hot, the coals smoking; put on the force-pump, put planks against the stanchions to keep the coals from falling from between deck, got more coals up. 2 p.m. Got to the coals that were on fire, which had been watered out. 5 p.m. No smoke or steam, kept the pump going till 7 p.m.; cloudy and gloomy looking to the westward; put the coals that were on deck overboard. 8 p.m. Commence pumping the ship out, kept off all hatches, and open all ventilators.

November 9th, lat. 31° 2′ S., long. 62° 31′ E., wind N.N.W., light breeze and cloudy, no smoke to be seen in the hole; dug down in the coals 9 feet from the 'tween-decks, the coals were hot, but no appearance of fire.

November 10th, lat. 29° 26′ S., long. 65° 58′ E. No fire or smoke to be seen in the hole; dug down into the coals, all felt cool, put in another ventilator in the after part of the hatch, no appearance of smoke or steam until the 21st.

November 21st, lat. 8° 32′ S., long. 69° 5′ E. Light variable winds and calms; 2 a.m. smoke was seen coming up the quarter hatch ventilator; commence to get the coals up, put them in the main hatch and on deck; 5 a.m., down as far as between decks, coals hot, smoke suffocating, which caused some of the crew and myself to vomit, and made them unable to proceed with work for a time; was then only able to fill three beef casks and be relieved by others, the force pump at work, taking the coals up at the same time; by noon down 7 feet below 'tweendecks, no smoke to be seen; kept all hatches and ventilators open.

November 22nd, lat. 7° 13′ S., long. 69° E. Light variable winds, no smoke, coals hot, got some more on deck; dug down 10 feet from between decks, saw steam but no smoke, put another ventilator in the fore part of the hatchway.

November 23rd, lat. 6° 32′ S., long. 69° 07′ E. Light breeze from the westward, took some more on deck as they felt hot, kept the pump at work for about an hour when all felt cool.

December 11th, lat. 12° 58′ N., long 70° 16′ E. Fine weather 7 a.m.; smoke was seen coming up the forehatch; trimmed the coals in between decks aft, got them up from lower hold and put them in between decks; by noon got to the coals that was burning kept the force pump at work for about an hour when all felt cool.

December 12th. No appearance of fire.

19. Not until after the first fire, but was tried after by thermometers.

20. In the main it was, but could crawl fore and aft the ship in the wings.

21. Always open only in bad or wet weather. No water got down.

22. Perseverance to get to the place that was on fire, and would do the same again if ever it was my lot to be in the same predicament, but will be glad to hear of some improvement.

23. Force pump with hose.

24. To the dust left in the wake of the hatches and a current of air could not get through amongst them. I would propose to have large ventilators that a man could get down and clear the dust or small coal with a rod of iron and take the dust and coal out of it to the bottom of the ship, also a small ventilator fore and aft in the body of the coals to be led to the main ones.

Mr. William Buchanan, of Greenock, also sent an enclosure relative to this case, and states in reply to questions No.

9. Splint coal from Messrs. Scott and Gilmours' Collieries Wishaw district, screened at pit but don't know whether double or single.

24. Some mineral defect in the coal as many vessels loaded from same pits took fire.

"SERENA." *

From Captain George Symons, Swansea.

1. "Serena," 16 A1; three years sailing.
2. Swansea, October 1869.
3. Valparaiso, but put into Rio de Janeiro.
4. Indication of fire off Madeira. Put into Rio December 5. Condemned and sold the cargo. A crew kept employed throwing water on it for the purpose of working it out.
5. Wood and iron.
6. No.
7. 493 tons.
8. About 720.
11. Yes, as previously mentioned; yellow pine planks.
12. An intense heat all over the hold, and stunk of sulphur. Am certain, another week and it would have been all fire.
13. From October 20 to December 6.
14. Cant say.
15. From wagons, 40 feet fall.
16. Very fine.
17. Dry throughout.
18. Actual fire did not break out; a few days more was only required. Indication, top of cargo quite green, similar to metals calcined, and smell exactly same (suffocating); had to live on deck for some days previous to entering Rio.—Much slate in this coal; when discharging it came out white with heat, and smelt strong of sulphur. I think this slate in cargoes highly dangerous.
19. Frequently with them.
20. No. Could walk and crawl over it.
21. Hatches daily open. Water was thrown down, the day I bore up for Rio, for the purpose to cool it.
22. Turning it over and over, and ultimately jettisoned a portion.
23. None. Pump.
24. Veins of sulphur in more or less of the coal, and slate as above. A coal owner once told me there are veins in mines or pits that should not be mixed with coal for long voyages; but the colliers will do it if not watched. No doubt there is something in this. *Memo.*—Last February I was at F. Isles—(went out about the "Alpha"),—and in Stanley there were five ships with different kind of coals on board. All put in with coals on fire. Cargoes ventilated in the usual way. Two of my voyages exceeded four months. A full cargo of coals, and not ventilated, turned out cool and in good order. Consequently I think it's a spontaneous vein in and about some pits that will ignite when in a heap of some tons, whether ventilated or any other precaution used. (I allude to the Swansea copper ore fitted ships in ventilation, which is evidently the best plan.)

"GLARAMARA."

From Messrs. John Brymner & Co., Greenock.

1. "Glaramara," about 13 years A 1, sailing.
2. Greenock, May, 1870.
3. Matanzas.
4. Off Cuban Coast, July 1870.
5. Wood.
6. Tight ship.
7. 475 $\frac{45}{100}$, and 449 $\frac{28}{100}$.
8. 660 tons.
9. Wishaw Main coal.
10. John Brymner & Co.
11. Partially with wood.
12. Apparently in forehold.
13. About 60 days.
14. Believed to be fresh dug.
15. Partly by hand, partly by drop of from 8 to 10 feet.
16. Fine weather during loading, apparently the same during voyage.
17. Dry.
18. Slight smoke shown for two days before fire broke out.
19. Cannot tell.
20. No.
21. Have no information.
22. Water poured down the hatches.
23. None.
24. Captain could not suggest any reason; informed us he had taken every precaution; except day after fire was seen when there was a violent squall, with rain, &c.

"VANDA."

From Messrs. Stoddart Brothers, Liverpool.

1. "Vanda," A1 at Lloyd's; age five years. Sailing ship.
2. Shields; River Tyne, May 1870.
3. Calcutta.
4. Near Cape of Good Hope. Was abandoned on fire 28th July 1870.
5. Wood.
6. None.
7. 1,081 under deck. 1,141 gross.
8. 930 tons; remainder of cargo was 560 tons coke, and 11 tons bricks.
9. Do not know.
10. Alfred Turner, esquire, Liverpool.
11. Do not think there was any special arrangement for ventilation. Captain instructed to keep hatches off when opportunity offered,
12. Cannot say.
13. A little over two months.
14. Do not know; perhaps 12 to 18 hours.
15. Loaded from waggons by spouts; cannot say the height.
16. Do not know.
17. Do not know.
18. Cannot give particulars. Captain at sea; letters put away.
19. Cannot say.
20. Coal and bricks in lower hold and coke in 'tween decks.
21. Cannot say.
22. Cannot say.
23. Fire engine.
24. Cannot name any particular cause.

"MALABAR."

From Captain J. Galloway.

1. "Malabar," A 1, two years; sailing.
2. June 1870, London.
3. Batavia, Java.
4. July 25th, 1870; 29° S. latitude; 30° W. longitude.
5. Iron frame and iron-plated.
6. Quite tight.
7. 1,200 register.
8. 1,274 tons 14 cwt.
9. Langley Mill.
10. On ship's account.
11. Yes; horizontally on each side of keelson, and perpendicularly at each hatchway.
12. Main hatch.
13. Thirty-six days.
15. By hand-basket from coal barges.
16. Dry weather and fine weather till discovering fire.
17. A portion taken in wet from leaking in barges, but no water afterwards got near them.
18. No indication until the smoke was discovered.
19. Not taken.
20. No, only two thirds cargo on board.
21. Hatches constantly open, and no water got down.
22. When we observed smoke threw about 50 tons overboard, and worked force pumps for two days until compelled to close hatches.
23. Only the two force pumps.
24. Bad quality of coal and damp condition.

"L'AGOUHANNA."

From Captain William Kennedy.

1. "L'Agouhanna" 8 A1 five years old, sailing.
2. About 10th October 1870, Birkenhead.
3. Bombay.
4. About 25th January 1870, about 500 miles S.S.W. from Bombay.
5. Wood.
6. Ship tight.
7. Net 1,103, gross 1,130.
8. 1,600 tons.
9. This information to be had from Messrs. W. H. Ross & Co., Liverpool.
10. Refer to Messrs. W. H. Ross & Co.
11. Yes, explained in clause 4 other sheet, wood.
12. About mainmast.
13. About three and a half months.

---

* A subsequent case of combustion appears to have occurred in this vessel in 1870 under very similar circumstances.

15. By waggon, coal fell about 20 feet to hatch coomings.

16. Showery.

17. Damp when shipped.

18. Yes, by quantity of steam rising from hold about three days before fire occurred.

19. Once a week by thermometer; found very little difference in temperature till fire appeared.

20. No.

21. Hatches open at all convenient seasons, no water ever got down.

22. Applied force pumps.

23. Force pumps.

24. To the height coals fell into the hold.

"CEREAL."

From Messrs. **Hine Brothers**, Maryport.

1. "Cereal." A1. 13 years old. Sailing ship.

2. August 7th, 1872, Swansea.

3. Santos.

4. September 28th, 1872. 4–30 S. 27–30 W.

5. Wood.

6. Made no water.

7. 299 gross. No nett.

8. 488.

9. Half, Merthyr Dare Colliery, and the other half, Gravesend and Gellia Cadoxton Collieries. Double screened. Cannot tell which seams.

10. J. S. de Vasconcellos & Co., London and Liverpool.

11. Not ventilated.

12. In the centre.

13. 60 days.

14. Fresh wrought.

15. Loaded from spout, the outer end of which to the hatchway was about five feet.

16. Rained all the time of loading. Fine weather until she took fire.

17. Wet.

18. Felt heat about week before fire broke out. No smoke until the day before flames broke out.

19. No.

20. Not nearly so; three feet from main hatch, five feet from fore and after hatches, and both ends of the ship empty.

21. Open all the time and no water ever got down.

22. Captain never expected ship was on fire until day before flames broke out. Time occupied in preparing and provisioning boats which was just accomplished in time Bore away from Pernambuco in hopes of scuttling ship there.

23. No special appliances.

24. Probably on account of being fresh wrought and shipped in a wet condition, combined with perhaps the fiery nature of the coals. This latter is only a surmise.

"BIVOUAC."

From Mr. **William Laing**.

1. "Bivouac," 20 years in Red, in Liverpool book, built in 1871, steam.

2. Sailed 23rd October 1872 from Newcastle-on-Tyne.

3. Odessa.

4. Between Gibraltar and Malta beginning of November 1872.

5. Iron.

6. None.

7. At that time $\frac{1122}{721}$ gross nett, now $\frac{1126}{723}$ gross nett.

8. 1,229 tons cargo.

9. Not known.

10. George Pyman & Co.

11. Yes, with galvanized iron cowled ventilators, two to each hold or compartment.

12. Main hold.

13. About ten days.

14. Not known.

15. By a staith or spout in the Northumberland Dock. Height not known.

16. Wet at time of loading.

17. Wet when put on board.

18. A light steam was seen a day before the fire broke out, but was supposed to be caused by the moisture evaporating.

19. No.

20. Not known, but very improbable, she being a three-decked ship.

21. As far as I know, hatches were never open, as weather was bad.

22. The cargo was carefully watched, and when it was noticed to be burning, holes were cut in the deck, and the ship's pumps brought to bear with the fire-hose inserted, which very shortly extinguished it.

23. Nothing special beyond the ordinary fire-hose attached to the engine pumps.

24. The wetness of the coals through being shipped at a time when heavy rains prevailed, and possibly aggravated by proximity to boiler bulkhead, which, however, was properly sheathed.

"HENRY BATH," "ALPHA."

From Captain **A. Peare**, Swansea.

1. "Henry Bath" and "Alpha," both sailing ships, A1 13 years, "Alpha" built 1863, "Henry Bath" 1864.

2. "Henry Bath," December 1872, at Swansea; "Alpha," July 1874, at Swansea.

3. Chili, West Coast of South America.

4. Off Cape Horn in both cases, about 70 days after sailing.

5. Wood.

6. Very little.

7. "Henry Bath," 486 register, 680 gross; "Alpha," 390 register, 560 gross.

8. 650 and 650.

9. Smelting coal, Mynyddy Bach.

10. Henry Bath and Son.

11. Planks on each side of stanchions from the keelson to the upper deck beams.

12. "Alpha," under fore hatchway; "Henry Bath," between fore and main hatchway.

13. About 70 days.

14. A short time.

15. "Henry Bath" loaded with boxes, lowered down to main hatchway before tipping; "Alpha" from spout or shoot that came down to the hatch.

16. Wet weather in both cases.

17. Wet when shipped.

18. Found the cargo getting heated, threw some overboard, and turned over as much as possible of the remainder.

19. Occasionally.

20. Filled up in the main hatch, not in the wake of fore and after ones.

21. Booby hatch aft nearly always open.

22. As mentioned above, and in the "Alpha" case pumped water into hold when the heat increased.

23. Pump.

24. The coal being small and wet.

"COUNTY OF NAIRN," "COUNTY OF PERTH."

From Messrs. **R. & J. Craig**.

1. Sailing ships, "County of Nairn," 16 years A1, three years old; "County of Perth," new 100A.

2. "County of Nairn" finished loading 3rd May 1873; "County of Perth" finished loading 4th July 1874.

3. "County of Nairn," Java; "County of Perth," Calcutta.

4. "County of Nairn," near Sourabaja; "County of Perth," near the entrance to the Hoogly.

5. "County of Nairn," composite; "County of Perth," iron.

6. Both ships were perfectly tight and had not at any time made water.

7. "County of Nairn," 1,047 gross, 999 nett; "County of Perth," 1,696 gross, 1,626 nett.

8. "County of Nairn," 600 tons; "County of Perth" 1,600 tons.

9. "County of Nairn," Hamilton Coal Company; "County of Perth," Roughrigg coal; both double screened.

10. "County of Nairn," James Finlay & Co.; "County of Perth," The Queen Steam Ship Company.

11. "County of Nairn," eight 12-inch ventilators and one 21-inch, of iron, all through main deck, and three iron mast ventilators; "County of Perth," one 28-inch wood from main deck to bottom of hold, with iron bell-mouth, and ten 12-inch of iron through main deck, and three iron mast ventilators.

12. "County of Nairn;" combustion took place in main hatch, lower hold; "County of Perth," combustion took place near the main hatch, in lower hold.
13. "County of Nairn," 110 days; "County of Perth," 114 days.
14. Direct out of the pits in the case of both ships.
15. Coals carted alongside of the ships and wheeled on board. The fall from planks to bottom of hold would be for "County of Nairn" 24 feet, and "County of Perth" 27 feet.
16. Fine dry weather during both loading and voyage.
17. Apparently dry when shipped and during voyage.
18. No indication of heating observed in either case, but a smell of gas was observed the evening before the fire broke out in the "County of Perth."
19. We are not aware whether the temperature of the hold was noticed during the voyage.
20. "County of Nairn," four-fifths of lower hold to a height of three feet; "County of Perth," about four-fifths of lower hold, from ceiling to a height of 7 to 8 feet, and about one-third of 'tween decks to a height of 3 feet.
21. "County of Nairn," hatches off nearly the whole voyage, and while discharging in Batavia; "County of Perth," the hatches were off nearly all the voyage till the evening before the fire, when they were put on in consequence of heavy rain; no water got down.
22. Fire hose from both pumps playing on the coal.
23. No other appliances but the fire hose and pumps.
24. Cannot attribute any cause for the spontaneous combustion.

"PERSIA."

From Mr. George Duncan.

1. "Persia," A1 9 years, built in 1853 (almost rebuilt in London, 1865).
2. Cardiff, 15th May 1873.
3. Aden.
4. Aden, 4th September 1873.
5. Wood.
6. None.
7. 1,704 net, 1,806 gross.
8. 2,087 tons.
9. Insoles Merthyr Steam for the Peninsular and Oriental Company.
10. Insole and Sons.
11. Same as stated in the "Indian Empire's" case.
12. In the way of the fore hatch near the bottom.
13. 112 days.
14. Cannot say.
15. Loaded from waggon which came very near the hatchway.
16. Good weather and favourable voyage.
17. Cannot say.
18. No; found on fire when discharging.
19. No.
20. No.
21. It is a standing order for hatches to be off during good weather. Believe no water went down.
22. Fire extinguished by aid of ships' fire engine hose. Ceiling was little charred.
23. Fire engine and head pump.
24. Cannot say.

"PRINCE ALFRED."

From Mr. Gates, Shoreham.

1. "Prince Alfred" (barque). Totally lost; burnt through combustion. Sailing vessel.
2. June 1873. Hull.
3. Galle.
4. Indian Ocean. Will obtain date, but think in August 1873.
5. Wood.
6. No, quite tight.
8. About 600.
9. I am unable to give the name at present.
10. I will find out, but cannot say now.
11. I believe it was not ventilated.
12. I believe the fore part.
13. I think between two and three months.
14. I cannot say, but understood they were shipped immediately.
15. I cannot say how great a fall.
16. I believe dry and warm.
17. I believe dry.
18. Yes, for some days before.
19. I cannot say, but believe not.
20. No.
21. I am not able to say, but believe water was thrown into the hold.
22. Hatches were battened down, but fire burst through deck.
23. No other than buckets.
24. Ignition of timber through combustion.

I shall be glad if I can in any way give information, but think the captain would be able to give more valuable information.

"CHANNEL LIGHT."

From Mr. Charles Beades, Lancaster.

1. "Channel Light," sailing, 6 years, and reclassed in August 1873 for six years.
2. Hull.
3. Rio.
4. Rio, October 1873.
5. Hackmatack, &c.
6. No.
7. 553 tons.
8. About 750 tons.
9. Do not know the name of the colliery.
10. Messrs. Wilson & Sons, 57, Great Church Street, London.
11. Yes, iron and wood.
12. Hold.
13. From 15th August to October 1873.
14. Short time only.
15. Tips trunk resting upon the deck.
16. Fine.
17. Dry.
18. No indication until after arrival at Rio.
19. Do not know.
20. No.
21. Do not know.
22. Ship moved into deep water and steam pumps used. Ship scuttled.
23. Force pump and hose.
24. Coal not laying long enough before shipment to let the gases escape.

"GEORGE DOUTHWAITE."

From Mr. Ralph Curry, Sunderland.

1. "George Douthwaite," built in 1860 at Blyth, Northumberland, 9 years A1, and continued.
2. 12th July 1873, Hull.
3. Constantinople.
4. First indications of combustion 6th September.
5. English oak frame, Stettin oak floors, planking inside and out, Danzig and Stettin oak, and American elm decks, Quebec yellow pine.
6. Ship quite tight.
7. 362 nett.
8. 626.
9. Reported as from South and West Yorkshire pits, double screened.
10. Cory Bros., of Cardiff.
12. Evidently amidships as main hatches blew off.
13. About two months.
14. Seven to 10 days out of pits before shipment.
16. Raining incessantly.
17. Wet decidedly.
18. By stilt and smoke first.
20. Main hatch, but not fore and after hatches.
21. After hatch would be open several times during voyage, as certain stores were in it on the cargo, lives, &c. No water would get down to the best of my knowledge.
22. According to captain's letter it seems to have been his intention to put the ship where she could be scuttled, and I fancy was afraid to take off main hatches for fear of giving free vent to fire.

The following is an extract from captain's letter:—

"I could do nothing else but put in here, she got worse every day; all hands were nearly suffocated with the smoke and dreadful stith; I bore up on Sunday night at 8 o'clock for this place, 11 o'clock at night she blew the hatches off, and sent sheets of flame up to the height of the main top. The wind came down the bay in the morning, so I had to beat up fresh breeze that set her going fast; the yellow smoke came rolling out like out of a steamer's funnel; as soon as we got in the entrance the men-of-war sent their boats with force pumps and played on the coals. Harbour master sent a steamer to tow her in. Put her into 18 feet water and scuttled her directly. The Greek men-of-war men and officers stopped on board all night to fill her up. An Italian frigate, a Russian gun-boat, and a Greek iron-clad are here, they all sent their assistance, about 50 hands on board us every day; commenced to pump her out yesterday afternoon; I shall hold survey to-morrow morning; cargo will have to be discharged, stores and spare sails all condemned in the Lazarette; could not get them up when we wanted, being full of smoke. Lloyd's agent intends to come to-morrow from Patras. The acting consul here told me to ask you to communicate with the Ionian Bank, London, about the money required here, &c."

23. No.
24. Think wet state of cargo when shipped.

"ST. MUNGO."

From Messrs. Gilmour & Co., London.

1. Sailing ship, "St. Mungo," built 1865, *A1.
2. Dundee, June 1873.
3. Point de Galle.
4. 13th September 1873, latitude 34° 57′ South, longitude 20° 18′ West.
5. Iron.
6. Perfectly tight.
7. 1,375 and 1,299 tons.
8. About 1,700 tons.
9. Townhill Colliery, steam coal, double screened.
10. Duncan Mitchell & Co.
11. Ship had 9 ventilators, fixtures, besides plank ventilators to all the hatches.
12. Aft, under poop.
13. Nearly three months.
14. Taken straight from the pit to ship.
15. From waggon, 10 to 20 feet.
16. Fine dry weather; very fair at sea.
17. Very dry.
18. Smoke seen on the 13th September, and she was abandoned 14th September.
19. Frequently.
20. There was a very large vacant space.
21. Nearly all the time.
22. Battened down to stop all draft.
23. Fire engine, &c.
24. Coal coming fresh out of pit.

"WALTER BAINE."

From Mr. J. S. Grieve.

1. "Walter Baine," AA1, 5 years, old sailing vessel.
2. Dundee, 8th July 1873.
3. Calcutta.
4. 27th September 1873, 39° 22′ S., 73° 19′ E.
5. Iron.
6. Never made water.
7. 898 tons nett, about 940 gross.
8. 1,170.
9. Spence's Wishaw Ell coal (Larkhalls district), single screened.
10. Baine & Johnston, Greenock.
11. Through ventilated; white pine was down the hatches and connected through along keelson.
12. Main hatch.
13. 81 days.
14. A few days.
15. From waggon; cannot say the height.
16. Very wet at time of loading.
17. Wet.
18. Refer to book by Rundell on Spontaneous Combustion on Coal Cargoes, page 46.
19. Not that I am aware of. Captain not in my employ now.
20. The bulk of coal was in the body of the ship, but not nearly loaded.
21. Cannot tell; believe no water ever got into the hold.
22. See Rundell's book, page 46.
23. Do.
24. I have a strong opinion the wet condition of the coal had a great deal to do with this case, and I do not approve of ventilators. I sent a new ship some months ago from Greenock, with 1,800 tons coal, and took care to ship only in dry weather; she arrived all right, after 120 days' passage. Another sister ship soon after was loaded with 500 tons coal and general cargo, for San Francisco, shipped in dry condition. She had 139 days' passage; arrived all right.

"ISABELLA KERR."

From Messrs. John Kerr & Co., Greenock.

1. "Isabella Kerr," 14 years A1, 9 years old, sailing.
2. August, at Dundee.
3. Calcutta.
4. 25th September, 32° 58′ S., 28° 28′ W.
5. Iron and wood.
6. Some water got in by side light, to which cause we attribute the fire.
7. 1,416 tons nett.
8. 1,955 tons.
9. Ell coal from Lanarkshire pits.
10. Ourselves.
11. Yes; wooden ventilator up each hatch and one along keelson.
12. After hatch, fore and aft in 'tween decks.
13. About seven weeks.
14. Cannot say.
15. From waggon at Dundee crane.
16. Wet during loading.
18. Captain found great heat coming up after-hatch ventilator five days before smoke came up.
19. No.
20. No.
21. Hatches kept open during fine weather; no water got down.
22. Heated coals were thrown overboard, and ship ran for St. Helena.
23. Force pump.
24. Water getting in through side light.

"ARRACAN."

From Captain C. S. Caird, Greenock.

1. "Arracan," sailing, 12 years, A1, A.M., 11 years old.
2. Cowpen coals; Howden dock, September 10th, 1873; North Shields.
3. Bombay.
4. February 16th, 1874; latitude 3° 40′ N., longitude 67° E.
5. Oak, Hackmatack, and pitch pine, all copper fastened.
6. Half an inch per hour.
7. 1,010 and 1,040 tons.
8. 1,441.
9. Cowpen coals.
10. Joseph Fothergill.
11. Six openings of two planks from beam to beam in between decks for the lower hold, two built ventilators in the house each end for the deck, and two hatches, one each end.
12. Supposed to be about fore rigging, starboard side, below the betwixt deck.
13. Five months and seven days.
14. Can't tell.
15. Waggon, 27 feet run, 26 feet fall (60 to 70 feet).
16. Fair; fair and rain.
17. Dry; dry during voyage.
18. Smell rising and hot in the fore hold on 14th February 1874; battened down. 16th; she fired two days.
19. Felt heat forward four months out.
20. Ship very open in the hold; could crawl fore and aft.
21. Half of the voyage; no water known to go down.
22. Battened down; three times burst open; drown out by water.
23. Two pumps for deck cleaning.
24. Damp in the small coal in the hatchway.

"INDIAN EMPIRE.

From Mr. George Duncan.

1. "Indian Empire," *A1, built 1865, sailing ship.
2. Shields, 27th September 1873.
3. Bombay, calling at Galle.
4. Off Cochin, 11th January 1874.
5. Iron.
6. None.
7. 1,515 nett.
8. 1,977.

9. Howard's West Hartley, best quality, steam, double screened.

10. J. R. Liddell.

11. Longitudinal shaft on each side keelson, and upshafts connected therewith coming up out of each hatchway.

12. About 8 feet aft the quarter hatch, in lower hold.

13. 102 days.

14. Cannot say.

15. Loaded at a spout in Northumberland dock, Tyne; ran down spout about 20 feet long.

16. Nothing particular as to wet while loading; fine during voyage.

17. Cannot say; believed in ordinary state.

18. Warmth felt in ventilators on deck three days previously, and subsequently a yellow smoke came up shafts.

19. No.

20. No; a considerable space in 'tween decks and at the ends of ship.

21. It is a standing order for hatches to be off during good weather; believe no water went down.

22. Hatches battened down till fire burst out; then ship was beached and scuttled.

23. Fire engine and head pump.

24. Coals shipped too soon after being dug, and not sufficiently screened.

"MOORESFOOT."

From Messrs. W. & R. Wright.

1. "Mooresfoot," A1, 10 years, sailing.

2. December 1873, Shields.

3. Bombay.

4. 10th March 1874; latitude 27° 30′ S., longitude 73° 30′ E.

5. Iron.

6. Perfectly tight.

7. 1,183.

8. 1,664 tons 4 cwt.

9. Howard's West Hartley.

10. Livingston, Briggs, & Co.

11. Ventilated by venetianed shafts up each hatch and along each side of her large box keelson; wood.

12. Supposed to be aft.

13. Three months.

14. Unknown.

15. By tip; height of fall unknown.

16. Unknown.

17. Unknown.

18. "Something was discovered coming up the fore hatch "at times having the appearance of smoke and accom-"panied by a strong smell of gas." As quoted.

19. Unknown.

20. No.

21. The captain has left no record.

22. Dug into the cargo to find out the seat of fire, battened down hatches, and closed ventilators.

23. Fire engine, hose, and buckets.

24. Have no idea.

"JOHN."

From Captain John Frostick.

1. Barque "John" sailing vessel A1, age 13 years.

2. September 12th, 1873, Porthcawl.

3. Valparaiso.

4. Seventy miles south from Cape Horn.

5. Wood.

6. No.

7. 367.

8. 564.

9. Abbw Smelting Coal unscreened.

10. Henry Bath & Sons of Swansea.

11. Hold ventilated with two half-inch boards on each side of stanchions from main keelson to deck beams.

12. In after hold.

13. 102 days.

14. About 24 hours.

15. Waggon. I should think the coals had to fall 30 feet.

16. Very wet, fine until off Cape Horn.

17. In after hold very wet, in fore hold moderate.

18. By gas and smoke in forecastle 60 hours before the flames burst through all.

20. No quite.

21. Every day when the weather was fine enough. No water got down.

22. All combustible matter taken on deck; all hatches battened down; four feet of water let into hold and ship put before the wind for the nearest port.

23. None.

24. The cargo being put on board in a wet state.

"ANNA."

From Captain P. F. Van Overklift.

1. "Anna" of Rotterdam first-class 12 years old sailing ship.

2. Cardiff, May 2nd, 1874.

3. Singapore.

4. 1st July 1874. 37° 14′ lat. S., 21° 25′ long. E.

5. Wood.

6. None.

7. 969 register tons.

8. 1,420 tons.

9. Insole's Merthyr steam coals, double screened.

10. Hypolite Worms, Esq., Cardiff.

11. Yes, with wooden pipes along the keelson and vertical ones in each hatchway (3). Two others from main deck to 'tween decks. Hatchway kept constantly open except during rainy or bad weather.

12. First about 9 feet down from surface of coals in the main hatchway. Afterwards about 15 feet from the deck or three feet from the bottom.

13. About 60 days.

14. Cannot say.

15. From waggons; there was but little fall for the coals.

16. Very fine and dry.

17. Coal appeared dry and was very dusty.

18. There was no fire but the coal became gradually very hot; temperature on deck 55° Farenheit, below 110° Farenheit.

19. Yes, twice daily every time the temperature was higher. An iron bar was forced down among the coal, this became so hot as to blister the hand when withdrawn.

20. No; forward and aft there was much space, in the middle of the ship the coal reached nearly to the decks.

21. Hatches open nearly all the voyage, only closed for rain or bad weather, hatchway in cabin always open.

22. I threw overboard about 300 tons of coal 38° S. lat. 1 East long. twenty days after (20) in 33° S. long. 78° E. long.; bad weather caused the closing of the hatchways for everal days during the time; the coal heated again but radually cooled down.

23. A force pump complete with hose always ready for use but not required.

24. To the peculiar character of the coal; I have carried coals several tons before but never met with a similar case.

"EUXINE."

From Mr. E. Bates.

1. "Euxine," iron sailing vessel, A1 20 years, built 1847, rebuilt by Laird 1869.

2. Loaded Newcastle, 12 June 1874.

3. Aden.

4. Abandoned on fire, 8th August 1874, about 1,500 miles south of St. Helena.

5. Iron.

6. None.

7. 1,594 tons.

8. 2,061¾ tons.

9. Howard's West Hartley.

10. Livingston, Briggs & Co.

11. Wooden additional ventilation. Iron permanent ventilation.

12. Supposed main-hold under main-hatch.

13. A few days over two months.

14. Unknown; believed a short time, waggons coming direct from pit.

15. Tipped along a shoot into the hold.

16. Fine.

17. Unknown.

18. In gale, 1st August, coals had shifted; while crew were engaged trimming, found great heat about main hatch; 4th Aug. ship trimmed upright; 5th Aug. coals smelling strong of gas, and smoke coming up main hatch.

19. Not known.

20. No, a space under each of three decks for ventilation, and on upper deck but little coal stowed.

22. Water pumped into hold continuously after fire discovered; 50 tons hot coals thrown overboard; coals afterwards so hot, hatches battened down; 6th Aug. hatches blew off; gas and smoke coming up ventilators.

"OLIVER CROMWELL," "CALCUTTA."

From Mr. Wm. R. Price, London.

1. "Oliver Cromwell" and "Calcutta," both colonial-built sailing ships, 1,112 tons and 1,372 tons nett register respectively, aged respectively eight and 10 years, both A1 at Lloyd's.

2. "Oliver Cromwell" sailed 18th June 1874. "Calcutta" sailed 2nd July 1874, both loaded at South Shields.

3. Of both, Aden.

4. "Oliver Cromwell," 6th September 1874, lat. 37° S., long. 14° E. "Calcutta," 17th September 1874, lat. 35° S., long. 7° E.

5. Both ships constructed of wood.

6. Both vessels were perfectly watertight, and made no water.

7. "Calcutta" (under deck), 1,261 tons, gross 1,372 tons. "Oliver Cromwell" (under deck), 1,013 tons, gross, 1,112 tons.

8. "Calcutta," 1,802 tons, "Oliver Cromwell," 1,616 tons.

9. B/L stated coal to be Howard's West Hartley. Cannot give any information as to the seam or whether double or single screen.

10. Charterers of ships were Mesrs. Livingstone, Briggs, & Co. on account of the Peninsular and Oriental Company.

11. Mode of ventilation described in clause 3. Material wood.

12. Fire in each case found to be in lower hold under main hatch.

13. About 85 and 82 days respectively.

14. Cannot say positively, but believe it was fresh from the pit.

15. By tips in Northumberland Dock, South Shields. Cannot state exact height, but it was considerable.

16. Fine.

17. What I saw on board the "Oliver Cromwell" was quite dry.

18. Please refer to clause 2.

19. The temperature was not, I believe, taken critically, but one of the crew of the "Oliver Cromwell" informs me that during the voyage he was frequently down in the fore and aft peak, and did not detect any unusual heat or vapour.

20. The hold was not completely filled in either ship, but the cargo was stowed high up to the main hatch, the ends being more open, but there was an unobstructed space from top of coals to deck the entire length of the ship.

21. The captain of the "Oliver Cromwell" stated to me that the first thing each morning, when he went on deck, he had the hatches taken off when the weather permitted, which it generally did. I did not learn that any water ever got down into the hold.

22. Water was poured down the hold, wet sails were put across the hatches and everything done to stop ventilation as much as possible.

23. Good fire-engine and plenty of hose in each case.

24. Speaking without any technical knowledge on the subject, I attribute these losses entirely to the nature of the coal. I may add that during an experience of about 25 years as an insurance broker I have largely insured coal cargoes to all parts of the world; with the exception of these two, I only had one case of burning, viz., the "Sir George Seymour," in 1867, from Birkenhead to Bombay, but in 1871, I effected insurances on the ships "Baringa" and "Sea Pink," the former an iron ship, the latter a wooden; both loaded from the Tyne for Bombay, neither of which were ever heard of, and as both were well found and well owned vessels, I have always considered that their loss was attributable to combustion rather than any other cause.

My experience, both as a ship owner and as shipping coal on my own account, is confined entirely to steam coal.

"EETA."

From Messrs. W. & J. Smith, London.

1. "Eeta," A1, 13 years, built 1874, sailing.

2. London, sailed 8th June 1874.

3. New Amsterdam, Berbice.

4. About 20th July, only a day or two before arrival in port, which she reached 22nd July.

5. Wood.

6. Not any.

7. 332 register.

8. 253 tons 7 cwt.

9.

Swadlincote	106	3
Baddersley	50	14
Babbington	96	10
	253	7

11. By a metal cowl ventilator forward and aft and screw ventilator in the bollards.

12. We think about midships, in the centre of the coals.

13. About 38 days.

14. Six to ten days.

15. From basket out of craft; they could only fall the depth of the hold.

20. No.

21. We had a very careful master and feel confident no water could have got down, and no general cargo was damaged, which must have been the case as the whole of the upper part was general.

22. General cargo was removed to give access to coals and water thrown down; this not proving effectual, we understand a hole or holes were bored in her to flood the floor and preserve the keelson, and everything done to smother it; the water washing in the hold greatly reduced it, and on arrival labour was obtained to discharge the upper cargo to put water on and pump, but the fire increasing she was taken on a mud bank and scuttled sufficiently to extinguish it. In this case only the coals were damaged, the ship and general cargo being saved.

"ALEXANDRE."

From Messrs. Agacio & Co., Liverpool.

1. French sailing ship "Alexandre," built at Glasgow, in 1869.

2. 23rd June 1874, Liverpool.

3. Valparaiso.

4. Took fire at sea, near Montevideo, and was scuttled to extinguish the fire.

5. Iron.

6. No.

8. 1,135.

9. Lancashire best orrell steam coal, double screened, bought from Messrs. W. H. Brancker & Co., Oldhall Street, Liverpool.

10. Ourselves.

11. The ships' hold was ventilated by means of a wooden case parallel to the keelson from fore to aft, 15-inch square, bored with holes and connected with three perpendicular similar cases projecting 4 feet over the hatches when shut.

12. Do not know.

13. She began to load in June 1874.

14. The coal was fresh wrought, but cannot state time before being put on board.

15. Loaded from waggons at the High Level Bramley Moore Dock.

16. Do not know.

17. Do not know.

18. Do not know.

19. In another ship, the "Coquimbo," the cargo was so heated that on her arrival at Callao, in March of this year, the captain found 40°/₀ of heat in the ship's hold.

20. Not completely.

21. Do not know.

22. Do not know.

23. Do not know.

24. Do not know.

"BRENHILDA."

From Captain Scurr.

1. "Brenhilda," A1, first voyage. Sailing.

2. 23rd June 1874. Glasgow.

3. Calcutta.

4. I cannot state to date exactly, on two different occasions I found the coals heated, smoking and smelling strong of gas. I turned them over and removed about 20 tons until all heat and gas subsided.

5. Iron.

6. No.

7. 1,321 tons.
8. 1,776 tons.
10. Watson.
11. Yes, one ventilator each hatch from upper deck to keelson, four large ventilators from upper deck to 'tween decks.
12. Fore hatch in lower hold.
13. About seven weeks.
14. I believe the coal came direct from the pit.
15. Waggon, by steam crane, about 5 feet from deck.
16. Very fine.
17. Dry.
18. Yes, refer to 4.
19. No, I examined the fore and after hatch daily, the main hatch never being unbattened.
20. No; from fore part of the fore hatch clear, and the after part of the after hatch 'tween deck hatches, all off; about 600 tons in 'tween decks.
21. Fore hatch open in fine weather, after hatch flap always open, and lee side of ventilators.
22. When heated turned them over, when fire broke out pumped water down.
23. Steam donkey pump, head pump, and fire engine, or force pump.
24. By coals coming direct from the pits.

The following letter was received by the owners from Captain Scurr:—

Gentlemen,

I beg to state that fire broke out 6th November in Calcutta in the fore hatch where I had turned the coals over on my passage out. I applied for the steam floating engine, and the port conservator sent it alongside at once, and put six jets on board, they putting 3 feet 6 inches water in the ship; in half hour all smoke and gas ceasing, I stopped pumping. At the time I should say I had discharged 500 tons of coal out of the main and after hatch. On getting down to the heated coals I found about 15 cwt. to a ton like a cinder or rather resembling coke. I have carried one cargo of coals out to Bombay from Sunderland, year 1866; 1,800 tons in the ship "Thomdean" with no ventilators, and never opened the main or after hatch, the fore hatch seldom; making a long passage of 130 days.

In 1853 I was seaman on board the ship "Hannah," from London to San Francisco with coals, no ventilators, the coals being six months on board and never heated.

John Scurr.

"ADMIRAL FITZROY."

From Mr. J. E. Burgess, Swansea.

1. "Admiral Fitzroy," 13 years, A1 10 years, sailing.
2. July 1874, Cardiff.
3. Valparaiso.
4. September 22nd, 1874, in lat. 53° 20′ S., long. 63° 8′ W.
5. Wood.
6. Very little.
7. 377 nett.
8. 525.
9. Insole's No. 3, Rhondda, worked from Cymmer Colliery, and from No. 3 Rhondda Seam, shipped through and through as worked.
10. Hy. Bath and Sons.
11. Main body of the cargo, say from abaft side mainmast to foremast, was divided by running deals up on either side of hold, stanchions from keelson to main deck, and left open at top.
12. Blew up all the main decks from fore part of main hatches to the poop; this took place at noon, and at 1 p.m. same day flames were coming up through the hatch.
13. Ten weeks.
14. A few hours.
15. By waggon; the first 120 tons would fall the depth of the ship, the balance would have only a few feet to fall.
16. Wet.
17. Slightly wet.
18. At 2 p.m. of the 21st September, a quantity of smoke was observed coming up the fore hatch, and on examination coals were found to be very hot and impossible to stop below. At 4 p.m. fore hatch was battened down, the cargo being evidently on fire; at noon of the 22nd inst. an explosion took place, which blew the main decks out from fore part of main hatch to the poop, and at 1 p.m. flames were coming up through the hatch.
20. Yes.
23. Not any.
24. I am unable to suggest any cause for this catastrophe, for the coals were shipped as No. 3 Rhondda, which is reported to be the purest coal in South Wales, and is entirely free from sulphur, whereas spontaneous combustion in coal is, I believe, usually attributed to water and iron pyrites, the unison of which gives rise to intense heat, something on the principle of slaked lime; if this was the cause of combustion in this instance, the coal must have been mixed, which may probably have been done (but now difficult to ascertain), as coals were very scarce at the time, and the vessel was on demurrage.

"DUMBARTONSHIRE."

From Mr. Thomas Law.

1. "Dumbartonshire," 100 A1., new, sailing ship.
2. June 1874, Glasgow.
3. Buenos Ayres.
4. 6th September 1874, at Buenos Ayres.
5. Iron.
6. Made no water.
7. 915 and 972.
8. 540 tons.
9. Splint. Russell's Colliery.
10. Owner.
11. Was only ventilated near main mast, but the mooring pipes acted as ventilators also.
12. Fore part.
13. About two months.
15. Was loaded by wheelbarrows.
16. Good weather both loading and during the voyage.
18. About 24 hours, by great heat.
19. No.
20. No. Ship had a general cargo.
21. Hatches were not opened often.
22. First poured water on coal, and then scuttled the ship.
23. Fire engine.
24. Cannot say.

"INDUSTRY."

From Mr. R. Robbins, Kenilworth.

1. "Industry," 5/6 L. 1. 1. in veritas, built in 1858; sailing.
2. July 1874, North Shields.
3. Bombay.
4. 19th October 1874, lat. 33° 47′ S., long. 52° 47′ E.
5. Wood.
6. None.
7. 1,138 tons.
8. 1,475 tons.
9. Davison's West Hartley Steam Coal, wrought out of Bidlington's collieries, most probably all from Low Main seam; ordinary single screened, as customary in the district.
10. Hickie, Borman, & Co. London.
11. Ventilator fore and aft, the ship's keelson and shaft through each hatch leading into it; the fore and aft hatches were never on, and ventilation well looked after.
12. After hatch.
13. Between three and four months.
14. They were drawn out of the earth and put at once into the ship.
15. From waggon by spout with a fall of about 24 feet when commencing to load.
16. Fine and dry, nothing of note occurred, no heavy seas got down the hatches.
17. The coals when shipped looked exceedingly well; were large, good, and dry.

Gas in cabin, and smoke from aft hatch two days before vessel was abandoned.

20. The ship was not full excepting in the main hatch, room at each end for about 90 tons.
21. See answer to questions Nos. 11 and 16.
22. All hatches opened.
23. None.
24. To the too rapid transition of the coal from the bowels of the earth to the ship's hold.

"MINDORA."

From Messrs. Stoddart Bros., Liverpool.

1. "Mindora," A1 at Lloyd's, built 1865, sailing ship.
2. Birkenhead, July 1874.
3. Bombay.

4. Took fire first on 16th October 1874, then on 29th November, and again 2nd December.
5. Wood.
6. None.
7. 971 tons register.
8. 1,416 tons.
9. Coal purchased from Robert James & Co., coal merchants, 3, George's Dock Gates, Liverpool, to whom refer.
10. Messrs. Edward Lawrence & Co., Liverpool.
11. Yes; a trunk on each side of the keelson the length of the hold and connected with it, a trunk up to each hatch and reaching above the deck; open at top; all of wood.
12. Main and after hatch.
13. About two months and a half.
14. Refer to Robert James & Co., George Dock Gate, Liverpool.
15. By the hydraulic tip at Birkenhead. The waggons are lifted by the tip and brought over ship's hatch. The greatest fall for coal would be about 10 to 12 feet. Ballast coal (350 tons) previously lowered into vessel's lower hold.
16. Weather fine when loading, and fine generally on the voyage.
17. Cannot say.
18. Early in October. Coals were hot.
19. Cannot say; captain is still abroad in the ship.
20. In the centre she was, and gradually tapered off to both ends.
21. Cannot tell; captain is still in India with the ship.
22. Captain does not state what he did at sea. On arrival at Bombay, on 2nd December, the water boat was sent to the ship and pumped water on the coal.
23. Fire engine.
24. Cannot determine any particular cause.

"STAFFORDSHIRE," "MONMOUTHSHIRE."

From Mr. D. Stuart.

1. "Staffordshire" and "Monmouthshire," A1, 11 years, sailing.
2. 1874, Liverpool.
3. San Francisco.
4. In both cases about 70 days out.
5. Iron.
6. None.
7. 1,172 and 1,167 tons respectively.
8. "Staffordshire," 814 tons; "Monmouthshire," 1,500 tons.
9. Lancashire steam coal, White Moss coal; single screened.
10. J. G. & W. Barnes.
11. Yes; the ordinary mode; wood.
12. Lower hold.
13. About 100 days.
14. A very short time, to the best of my knowledge.
15. From the high level. The fall was small.
16. Very fine.
17. Quite dry.
18. Only a few days.
19. I am unable to answer.
20. In the second case, yes; in the first, no.
21. I do not know.
22. In the first case the ship was taken to the nearest port and scuttled. In the second case the fire was promptly extinguished and a small jettison effected.
23. Ordinary fire-engines.
24. The newness of the coal solely.

"GLEN TILT."

From Messrs. Hughes & Co., Menai Bridge.

1. Sailing ship, "Glen Tilt," A1, built 1865.
2. July 30th 1874, Cardiff.
3. Coquimbo (Chili).
4. October 28th, 1874, off Cape Horn.
5. Wood.
6. Little or none.
7. 991 tons net.
8. 610 tons coal, 591 tons coke.
9. Non-screened smelting coal, Pen-y-graig colliery.
10. Pen-y-graig Coal Company.
11. Ventilated with platform under cargo.
12. Between the after part of fore hatch and after part of main hatch.
13. From date of leaving Cardiff, 30th July, to arrival at Port Stanley, Falkland Islands (to which place ship put back to), 11th November.
14. Cannot say.
15. Depth of hold 21 feet; it slid down the shoot to combings of hatches.
16. Very fine dry weather.
17. Very moist.
18. None that we are aware of.
19. Cannot tell.
20. Not quite; large space forward, coal being in *the bottom* and coke on the top.
21. We believe hatches were not opened, nor did any water get down.
22. Cargo was got up to get at the fire, but it became too hot to work, and then the hatches were battened and well caulked. Ultimately the decks got very much heated, and holes were then bored in the decks and waterways to pour down water.
23. Pumps.
24. To gas, inferior quality, and damp state of the coals at time of shipment.

"ONTARIO."

From Messrs. John Vaughan & Co., Liverpool.

1. "Ontario," 3/3 to 1.1., Veritas; built 1861. Sailing vessel.
2. 1 to 7 of August 1874, at Tyne.
3. Bombay.
4. 22 January 1875, at sea.
5. Wood.
6. Perfectly tight.
7. Her net register tonnage is 1,062 tons.
8. About 1,500 tons coals, and 100 tons coke.
9. West Hartley Main coals.
10. Livingstone, Briggs & Co., London.
11. Was well ventilated, a ventilator in each hatch, and along each side of the keelson under the coals.
12. Main hatch.
13. About 5½ months.
14. Unknown to us.
15. The vessel loaded from tips, not from waggons.
16. Fine, with occasional showers; weather during voyage unknown to us.
17. Unknown.
18. No indication given, until volumes of smoke issued out of the ventilators.
19. No.
20. No.
21. Unknown to us.
22. Water was poured down, and the vessel run ashore and scuttled.
23. Fire-engine.

"NORTHBROOK."

From Messrs. Adamson and Ronaldson, London.

1. "Northbrook." When new, 100 A 1. Sailing ship.
2. August 1874. The Tyne.
3. Madras.
4. December 1874, Madras Roads.
5. Iron.
6. None.
7. 1,820 tons net, 1,876 gross.
8. 1,656 tons coal and 866 coke.
9. Not known.
10. James Burgess and Sons.
11. By iron ventilators, and a free current of air through the hold.
12. After hold, immediately under hatch.
13. 120 days.
14. Not known.
15. From waggons; about 30 feet.
16. Changeable.
17. Slightly damp.
18. None.
19. Occasionally.
20. No.
21. Closed only during very bad weather or much rain; a small portion of water may have got below.
22. The hatches were immediately closed, and a hose supplied by a steam pump, pointed to the seat of fire, and a constant supply of water kept up.
23. Steam pump.
24. Damp.

"NEW LAMPEDO."

From Messrs. Seed, Armstrong, & Co. Liverpool.

1. "New Lampedo" 3·3, 11 Veritas 5 years, age about 10 years, sailing ship.
2. 10th August, 1874. Liverpool.
3. Panama.
4. Abandoned 16th November off Cape Horn.
5. Spruce and hackmatack with birch floors.
6. Made no water.
7. Nett 1,099, gross about 1,127.
8. 1,499 tons.
9. Don't know.
10. J. G. & W. Barnes.
11. Her San Francisco grain lining was left in up to her 'tween decks which was Oregon pine; deck ventilators fore and aft.
12. It was supposed the fire originated in the main hatch low down.
13. Three months.
14. Don't know.
15. From the height of her decks.
16. Very wet weather at the time of loading.
17. Coal very moist when taken on board.
19. No.
20. No.
21. Hatches open at all times when possible; no water got into hold.
22. Battened down when there was indication of fire.
23. None.
24. Cannot tell.

"ENTHUSIAST."

From Messrs. W. & J. Smith, London.

1. "Enthusiast" A 1, built 1854, sailing ship.
2. Sailed from London, about 11th August 1874.
3. Demerara.
4. Abandoned at sea, 14th September, on fire.
5. Wood.
7. 283 register.
8. 114 tons.
9. Swadlincote, single screened.
13. She was abandoned on fire, 14th September, shipped about 21st or 22nd July, say 53 days.
14. 6 to 10 days.
15. Out of basket from craft.
20. No, only a part of her general cargo.

"LA ESCOCESA."

From Messrs. Balfour, Williams, & Co. Liverpool.

1. Sailing ship "La Escocesa"
2. Cardiff, September 1874.
3. Valparaiso and Payta.
4. Five days previous to her arrival at Payta.
5. Iron.
6. No.
7. 946 net, 988 gross.
8. 1400 tons.
9. South Wales shipped at Cardiff; colliery, not known.
11. Yes, with fore and aft along keelson and three vertical ventilators as per sketch attached.
12. Amidships.
13. 130 days.
14. Very short time.
15. From coal tips at Cardiff.
16. Raining heavily.
18. Smouldering five days previous to the arrival; after the arrival the hatches were opened, 400 hundred tons discharged previous to actual fire.
19. Not known, captain not yet arrived home.
20. No.
21. Same reply as to No. 19.
22. Closed all ventilation when fire actually broke out, ship was scuttled by crew of ship with assistance of one of Her Majesty's frigates.
23. Fire-engine, hose and buckets.
24. Coals green and weather wet while loading.

"TRY."

From Messrs. W. and J. Smith, London.

1. "Try," A1, built 1866. Sailing.
2. London, sailed 4th September 1874.
3. Georgetown, Demerara.
4. 13th October, at sea; smoke found coming up fore hatch.
5. Wood.
6. There is no report of it in the protest.
7. 428.
8. 107 tons 15 cwt.
9. 57 13 Swadlincote.
   50 2 Hockley Hall.
   107 15
11. Being a sugar trader we think so, but do not know of our own knowledge.
12. Fore hold.
13. About 60 days.
14. Six to 10 days.
15. By basket from craft.
18. Not any.
20. No, only a small part of the cargo.
22. The cargo was got on deck and water thrown down until the fire was subdued.

"CRYSTAL."

From Messrs. W. and J. Smith, London.

1. "Crystal," A1 10 years, built 1872. Sailing ship.
2. 5th September 1874, from London.
3. Berbice River (New Amsterdam).
4. In the Berbice River; she arrived there 23rd October, and after discharging nearly all general cargo the coals were found on fire, we think it was about 31st October.
5. Wood.
6. Not any.
7. 263.
8. 239 tons 5 cwt.
9. 102 tons 11 cwt. Hockley Hall, 136 tons 14 cwt. Swadlincote; as to seam, &c.
11. By two cowl metal ventilators, one forward and one aft, and the after hatch was frequently off we believe in fine weather.
12. Near the foremast and within a few feet of the ventilator.
13. Under 80 days.
14. Six to 10 days.
15. By baskets from lighters. They fall only from deck to bottom for first few tons, and afterwards on the pile and run down.
18. Not any indication.
19. It was not taken as far as we know, but nothing excited attention during the voyage or discharge of the cargo stowed over the coals.
20. No.
21. We understand the weather was fine and we are quite confident no water would be allowed to enter; all the top was general cargo and she has an old, most experienced, and careful captain.
22. Immediately it was discovered it was subdued by water being thrown on the spot on fire, this operation being of course a simple matter in consequence of all the other cargo being out, and ship in port.

"KHERSONESE."

From Mr. George Duncan.

1. "Khersonese," 100 A1, built 1855, sailing ship.
2. Shields, 19th September 1874.
3. Bombay, calling at Galle.
4. Bombay, 20th February 1875.
5. Iron.
6. None.
7. 1,811 gross, 1,711 nett.
8. 2,022 tons.
9. Bebside West Hartley steam, best quality, double screened.
10. James Walton.
11. Same as stated in the "Indian Empire" case.
12. In the way of the main hatch, about half way down.
13. 154 days.

14. Cannot say; think some of it a very short time, say not more than 12 hours.
15. Loaded from waggon, coal falling 15 to 20 feet.
16. Weather showery during shipment, not seriously wet; rough passage out of the Channel, afterwards fine weather.
17. Cannot say; believed in ordinary state.
18. Fire broke out three days after commencing to discharge cargo; no previous indication.
19. No.
20. No; a considerable space in the three holds and at ends of ship.
21. It is a standing order for hatches to be off during good weather; believe no water went down.
22. Floating fire-engine brought alongside, and fire extinguished without damage to ship.
23. Fire-engine and head pump.
24. Coals shipped too soon after being wrought, and not sufficiently screened.

"THE FOUNDLING."

From Mr. E. Bates.

1. "The Foundling," A1, 20 years, and AA1, built 1866 iron sailing vessel.
2. Birkenhead, 24th September 1874.
3. Bombay.
4. 21st November 1874.
5. Iron.
6. None.
7. 1,186 tons.
8. Mixed cargo, 100 tons iron and 100 tons bricks, 200 tons coke; 795 tons Westminster Brymbo coals, 306 tons Oaks Pits coals.
9. North Wales Main steam coals; 795 tons from Westminster Brymbo Coal and Iron Company's Colliery, and 306 tons from Oaks Pits Colliery, Mold.
10. Edward Bates & Sons.
11. Yes; in addition to permanent iron ventilators a wooden shaft through the coals and down each hatchway.
12. Supposed in main hold under main hatch.
13. About two months.
14. Unknown; probably a week.
15. By tips; coals run down a shoot into the hold, falling the height from deck to coals.
16. Wet.
18. Smoke observed issuing from main ventilator on 19th November; hold full of smoke, 20th November; flames bursting out, 21st November.
19. Believe not.
20. No; ship was not full; large space over coals in lower hold.
21. No water got down; unknown time hatches were off.
22. 19th November, took hatches off, pumped water into hold for 2½ hours, then battened hatches down.
23. None.
24. Unknown.

"LEVANT."

From Mr. John Jones, Milford.

1. "Levant" class A1, 12 years, 9 years old last April, sailing.
2. September 1874, Swansea.
3. Valparaiso for orders.
4. 8th of January 1875. Lat. 60° South, long. 73° West.
5. Oak teak and green heart.
6. Did not make water.
7. 314 tons register.
8. 470 tons of coal, 10 tons of powder, 1 ton of fusees.
9. Smelting coal for copper works, do not know the name of the colliery, not screened.
10. Messrs. Elford, Williams, & Co., Swansea.
11. With three boxes one in each hatch, made of wood.
12. Seven feet before the foreside of the main hatch, and at the bottom of the vessel.
13. About 100 days.
14. Do not know.
15. From waggons, about 20 feet fall.
16. Partly wet, latter part dry; generally strong weather.
17. Did not observe.
18. Captain has left the ship, do not know.
19. Do not know.
20. Within four feet of the deck.
2., Do not know.
22. Threw the 10 tons of powder and 1 ton of fusees overboard and battened all down.
23. None, except buckets to pour water on the coal.
24. Do not know.

"CITY OF RICHMOND."

From Mr. Donald Kennedy, Liverpool.

1. "City of Richmond," 3/3 Veritas; 10 years old. Sailing ship.
2. Birkenhead, October 1874.
3. Bombay.
4. 9th March 1875, Bombay; combustion.
5. Wood.
6. None.
7. 1,284 total, 1,241 nett register.
8. 1,638.
9. Laird's West Hartley seam, to be double screened.
10. Messrs. Busaby and Wichelhaus, from Liverpool.
11. 3 in. deal (spruce) platform, with wooden ventilators up each hatch.
12. Believe about main hatch.
13. 4½ months.
14. A few days.
15. Tip.
16. Ordinary weather for season of year.
17. Ordinary state.
18. Found to be very much heated during discharge.
19. Don't know.
20. No.
21. Hatches open all fair weather; no water got down.
22. Water poured down.
23. Usual (ship) fire-engine.
24. Don't know.

"FEDALMA."

From Mr. J. Hamlyn (Master), by Messrs. Scrutton & Co., Shipowners.

1. "Fedalma," A1, 4½ years, sailing ship, barque.
2. 12th October 1874, Porthcawl, Wales.
3. "Valparaiso" for orders, ordered to Chanaral.
4. 6th February 1875, at Chanaral.
5. Iron.
6. Made no water.
7. Nett $478\frac{48}{100}$, gross $507\frac{41}{100}$.
8. 654 tons.
9. Smelting, from the "Aber Coal Company," not screened.
10. Messrs. W. Nicholson & Sons, Sunderland.
11. The ship was ventilated, fore and aft, by stantions from deck to keelson and 1½ boards nailed to them, thus leaving a space of 6 in. broad from top to bottom, and dividing the whole cargo in the middle.
12. On the starboard wing, from the after part of main hatch, and extended 20 feet aft, also from ceiling 4 feet up, the coals on fire being about 4 feet deep.
13. 117 days.
14. I do not know for certain, but was told they came direct from the pit.
15. The coals were shot from the wagon into a shute of about 20 ft. in length, and thus conducted to the combings of the hatchway; the depth of the ship's hold 16 feet 4 inches.
16. Fine and dry during the time of loading, not much rain during the passage.
17. Very dry when shipped and quite dry during the voyage, that is, having only the usual moisture in the dryed coals, viz., about 3 per cent.
18. The coals were warm just about 2 feet under the surface when we commenced to discharge, and when we got down about 4 ft. it became quite cool in all parts except the starboard wing, which got hotter the farther we got down, and the first indication was a jet of white steam, with the smell of paraffin oil which came from under the stringer.
19. Only by going into the hold and feeling with the hand, and this was done every day the hatches were taken off.
20. No, only about two-thirds full, falling from 2 feet 6 inches below the main hatch to nothing fore and aft.
21. Some part of almost every day; and I do not believe a bucket full of water went into the hold.
22. To discharge the coals as quick as possible, working all hatches to cut the fire off from going further aft.
23. Plenty of fire buckets.

CASES OF EXPLOSION.

THE FOLLOWING PARTICULARS OF CASES OF EXPLOSION OF GAS ON BOARD COAL-LADEN SHIPS HAVE BEEN SENT IN ANSWER TO THE FOREGOING QUESTIONS :—

"MEUSE."

From Messrs. N. PAQUET & Co., Marseilles.

1. "Meuse," built in 1872, steamer.
2. The 10th or 14th August 1874.
3. Port Said.
4. 23rd August, about 10 miles north-west of Cape Bengut Algiers.
5. Iron.
6. Did not make water.
7. $\frac{1234}{496}$.
8. 1,100 tons.
9. Invoice, stated, Wood's, Merthyr, large.
10. H. Worms & Co.
11. Not ventilated.
12. In the fore hold.
13. About eight days.
14. We do not know, probably not long, as the gas still existed.
15. By the ordinary method in use at Cardiff, from wagons which are lowered to the hatches.
16. Bad weather till we entered the Mediterranean, with fine weather from then till the time of the explosion.
17. Not known.
18. None.
19. Temperature was not taken.
20. There was a considerable space below the spar deck.
21. The hatches had not been off until such time that the explosion took place. It was said that the hatches were taken off the evening before but this was not well confirmed.
22. The heating of the coals was not detected until the explosion occurred, which caused us to return to Algiers, where the coals were discharged without further damage.
23. Nothing special beyond the pumps with which all steamers are supplied.
24. We believe that this explosion was caused by a man decending the hatchway with a naked light, and this man was the first victim of the explosion so caused. This was not a case of spontaneous combustion.

"HOLYROOD."

From Mr. E. C. DOWNING, Cardiff.

1. "Holyrood" steamship, of Limerick, A1, built in 1857.
2. Cardiff September 23rd, 1868.
3. Limerick.
4. September 23rd 1868 in main hold. Cardiff.
5. Iron.
6. None.
7. 296 net, 358 gross.
8. 585 tons.
9. Cardiff Merthyr steam coal, 414 tons from Ocean Collieries, 171 tons from D. Davis and Sons, Merthyr Collieries (through and through coal).
10. E. C. Downing.
11. Not ventilated at all.
12. Mainhold.
13. About 24 hours.
14. Probably not more than 24 hours, perhaps not so long.
15. Ex-waggons; the fall was very little, perhaps 2 or 3 feet.
16. Fine.
17. Dry when shipped.

19. No.

20. The hold was completely filled aft under the cabin, but there was room forward for 10 or 12 tons coal; the hatchway was quite filled up with coal. The cargo was shipped and then 71 tons coal for bunkers were tipped on the hatchway and wheeled to the bunkers; this occupied several hours; when done the men were about to clear the hatchway and one man went below to trim down the coal, another man handed down a *lighted* candle, when an explosion occurred damaging the steamer slightly, but seriously burning the two men.

24. To the want of ventilation and the exposure of a naked light.

"BATTALION."

From Mr. WM. LAING, Leith.

1. "Battalion." A1 two years. Steam.
2. 6th March 1863, Cardiff.
3. London.
4. 8th March 1863; channel; explosion.
5. Iron.
6. None.
7. 574–694.
8. 715 tons.
9. "Navigation" steam coal (late "Nixon's Duffryn").
10. Nicon, Taylor, and Cory.
11. Not ventilated.
12. Fore hold.
13. About four days.
14. Unknown.
15. Unknown.
16. Unknown.
17. Unknown.
18. No.
19. No.
20. No.
21. Unknown.
22. Unknown.
23. Nothing beyond engine pumps.
24. To the accumulation and concentration of gas in the fore hold, which was not half full, and contact with a naked light which a sailor carried down, in order to get the square-sail out of the hold.

"BROOMHAUGH."

From Messrs. ELLIOTT, LOWREY, and DUNFORD, Newcastle-on-Tyne.

1. "Broomhaugh;" 90 A1, 1872; steam.
2. September 1873 (sailed 14th), Cardiff.
3. Port Said.
4. 20th September 1873. Near Gibraltar.
5. Iron.
6. Ship made no water.
7. 1,352 tons; 865 tons.
8. 1,576.
9. Powell Duffryn steam coal; double screened.

11. Not ventilated.

12. Fore peak and fore hold.

(The explosion first occurred in the peak; the fire then penetrated to the fore hold, where there was also a vacant space, resulting in a second explosion there.)

13. Seven days.

14. A few hours.

15. From tips. Coals would run through a shoot for about 50 feet.

16. Very wet during loading; do. passage to Gibraltar.

17. Coals, considering the weather, would be much wet in transit from pit to ship.

18. None.

19. No.

20. None of the holds were full.

21. All the hatches off from loading till midnight of 14th. State of the weather would not permit of their being removed again until the explosion.

22. No indication until explosion.

23. Fire-hose and buckets.

24. September 1873.—All went well until the 20th of same month, when one of the crew having occasion to sound the water tank in the fore-peak, proceeded (having first provided himself with a lamp) to remove the hatch and descend into the peak.

Whilst standing over the hatchway with the lamp in his hand it was noticed by those in the vicinity that a blue light seemed to encircle the lamp, caused, no doubt, by the accumulated gas from the cargo in this unoccupied space; the gas becoming ignited burnt the man's hand, causing him to drop the lamp down the hatch. The effect was instantaneous. There was a loud explosion; the decks were blown up from the foremast to the forecastle; bulkheads blown down, and generally the fore part of the ship was made a complete wreck.

"THAMES."

From Mr. H. Cloake, Cardiff.

1. "Thames," steamship.

2. First explosion occurred May 1861 after loading at Swansea, second explosion was July same year from same port.

3. First voyage, Alicante; second voyage, Valencia.

4. First explosion occurred off or near Lisbon after being out about five days, severely burning chief engineer rendering him incapable of duty all voyage; second explosion occurred on leaving piers of Swansea and burning second engineer who had been ordered to take no light down in the tunnel or compartments.

5. Iron.

6. No.

7. 191 net, 302 gross.

8. 360 cargo and 60 bunkers.

9. First cargo, I believe, was Wayne's Merthyr single screened; second was a mixed cargo.

10. Cannot remember.

11. We had ventilators fitted in each hold, of the same description as those used for the stoke hole.

12. Both explosions occurred in the compartment aft, entrance to which was from the cabin down a trelliced hatch, but the gas had accumulated further aft. Engineer, who had been in boat some time, took a match down and struck light, but had been cautioned to use safety lamps.

13. First case about 7 days, second case not 24 hours.

14. I am under impression that coal was shipped soon after worked.

15. From trucks containing 8 to 10 tons each; the shute down which coal came from the trucks being on level with combings.

20. We had much space vacant in both holds.

21. On first occasion the hatches were occasionally off; on second occasion the hatches had not been on since loading. It is my opinion that often when hatches are off that much harm is done by salt water going down; being cargo coals it is supposed often that they cannot damage, but the wet during long voyages is the cause of most of the fires.

24. To accumulation of gas in the after end and a naked light being, used although against express orders and proper lamps being available.

"WILLIAM BATTERS."

From William Batters.

1. "William Batters." A. 90. New ship. Steam.

2. 16th and 17th September 1873; Cardiff.

3. St. Nazaire.

4. 18th September 1873. Penarth Roads just outside Cardiff.

5. Iron.

6. None.

7. 530 nett, 829 gross registered tonnage.

8. About 1,040.

9. Small coal collected from several collieries.

10. C. Goddard of Nantes and Cardiff.

11. No special ventilation, but the hatches were off at the time of the explosion.

12. In the fore part of the fore hold.

13. About 48 hours.

14. I could never ascertain, although I tried to do so at the request of underwriters.

15. From tips in the usual manner at Cardiff.

16. Fine.

17. Usual condition of small coal; did not present any difference as regards appearance.

18 and 19. The voyage had barely commenced.

20. Not at the part where the explosion originated.

21. See reply to 18th and 19th queries.

22. No such indications were perceptible.

23. A powerful donkey engine and fire hose.

24. There were two scuttles, alike in appearance and close together, one on the fore side of the forward bulkhead leading to the chain locker, and one on the after side leading to a store-room, taken out of the fore hold and constructed of wood; there is little doubt that the gas had passed through the joints and connexions of the wooden structure and accumulated in the store-room. The ship was weighing anchor at daybreak, a man went with a naked light to stow the cable in the chain locker, and instead of going down through the forward scuttle made a mistake, lifted the after scuttle, and the explosion was the result.

"J. H. LORENTZEN."

From H. Lorentzen.

1. "J. H. Lorentzen," steamship. 16 years at Liverpool. Age, built in 1872.

2. October 30, 1874, at Sunderland.

3. Hamburg.

4. South Dock, Sunderland, October 30th, 1874.

5. Iron.

6. No.

7. 567 net, 884 gross.

8. 1,056$\frac{4}{20}$ tons.

9. 611 tons Ryhope Hartley steam (best screened) and 445$\frac{4}{20}$ tons of Ryhope treble-screened nuts; out of Maudlin seam, Ryhope Colliery.

10. J. S. Barwick.

11. No.

12. In the fore hold where the steam coals were.

13. Just shipped.

14. A few hours.

15. From waggon into a spout that was level with the ship's hold.

16. Fine weather. Accident took place an hour after ship was loaded.

17. Dry.

18. No.

19. Ship had just commenced the voyage.

20. Very nearly.

21. See answer to No. 19.

22. None, because none were necessary as it was just an explosion that blew off the hatches and singed the paint a little.

23. Donkey pump.

24. Through the hatches being battened down too soon for coals that had just come out of the pit.

APPENDIX V.

STATISTICS prepared by LLOYDS especially for the Commission.

SHIPMENTS OF COAL, 1874.

TABLE showing the Number of COAL SHIPMENTS and the QUANTITIES SHIPPED from the UNITED KINGDOM to FOREIGN PORTS in 1874, and the NUMBER of CASUALTIES which occurred from SPONTANEOUS COMBUSTION.

(This Table was compiled by Lloyd's from Returns furnished by the Custom House Authorities at the various Ports of the United Kingdom.)

—	NUMBER OF SHIPMENTS.												QUANTITIES SHIPPED.					
	Cargoes under 500 Tons.	Casualties from Fire or Heat.	Cargoes 500 and under 1,000 Tons.	Casualties from Fire or Heat.	Cargoes 1,000 and under 1,500 Tons.	Casualties from Fire or Heat.	Cargoes 1,500 and under 2,000 Tons.	Casualties from Fire or Heat.	Cargoes 2,000 and upwards.	Casualties from Fire or Heat.	Total Number of Vessels.	Total Casualties from Fire or Heat.	Cargoes under 500 Tons.	Cargoes 500 and under 1,000 Tons.	Cargoes 1,000 and under 1,500 Tons.	Cargoes 1,500 and under 2,000 Tons.	Cargoes 2,000 Tons and upwards.	Total Quantity of shipped Tons.

September 1873	Arracan	Colin Caird (master)	1,010	12 „	Wood	A1	North Shields
September 1873	Indian Empire	Geo. Duncan	1,515	8 „	Iron	A1	Shields
December 1873	Mooresfoot	W. and R. Wright	1,183	10 „	Iron	A1	Shields
December 1873	John	John Frostick	367	13 „	Wood	A1	Porthcawl

---

* Almost rebuilt in 1865.

† The Isabella Kerr sailed again on 23rd Sept. 1874 with coal from Greenock for Bombay, and was posted at Lloyd's as missing 20th May 1875.

OF COALS.

I.

have been sent in answer to the Circulars of the Commission.

Port of Destination.	Quantity shipped, tons.	Description of Coal.	How loaded, Barrows or Tips.	Whether ventilated, and how.	How long Coal had been on board.	Supposed Cause and extent of Casualty.	Weather when loading.
Aden	750	North Welsh	From craft	Ventilated	Over 3 months	Ventilation; fire	Wet.
Valparaiso	1,050	Tyne	Dropped from deck 20 ft. first fall.	Not ventilated	Nearly 4 months	Want of ventilation and small coal.	Fine.
Shanghai	—	Resolven (hand picked)	Baskets and lighters.	Ventilated	4 or 5 months	Wetness of coal, ship burnt.	Wet.
Bombay	1,000 & 400 coke	Howard's West Hartley (double screened).	Spout	Ventilated	1¾ months	Wetness of coal, imperfect ventilation, height of fall; severe heating.	Wet.
Valparaiso	450	Smelting coal (not screened).	Waggon and shoot.	Ventilated	Over 3 months	Wet state of cargo; ship burnt.	Raining.
Quebec	442	Duke of Buccleugh (unscreened).	Waggon by crane.	Not ventilated	2 months	Quality of coal.	—
„	abt. 500	„ „ „	„ „	„ „	„ „	„ „	—
„	434	„ „ „	„ „	„ „	„ „	„ „	—
Shanghai	1,102	Bebside West Hartley and Cowpen Hartley.	Waggon	Ventilated	6 months	Ship scuttled	Pretty dry.
Calcutta	1,500	Townhill Colliery	Tubs	Partially ventilated	3½ months	Wetness of coal; ship abandoned.	Very wet.
Bombay	2,050	Westminster Brymbo (double screened).	Tips	Ventilated	5½ months	Loading by tips; fire extinguished.	Fine.
Valparaiso	1,804	Rhonda No. 3, thro' and thro'.	Barrows	Well ventilated	3 months	Nature and wetness of coal; heating, cargo discharged and sold at Monte Video.	Rain.
Aden	2,500	Welsh steam	Wheeled on board.	Ventilated but ventilationstove in and broken.	Nearly 3 months	Injury to ventilation and wet state of coal.	Rainy.
Bombay	1,830	Wishaw Coal, Lanark, (single screened).	Waggon	Ventilated	2 months	Ship burnt and abandoned.	Very showery.
Bombay	—	- - - -	- - -	- - -	5 months	Fire, extinguished by water.	—
Bombay	1,776	Splint coal from Scott and Gilmour's Collieries, Wishaw District.	Waggons	Ventilated	2½ months	To nature of coal which has fired in many vessels, and to accumulation of dust and small coal. Great heating.	Very dry.
Valparaiso	720	South Wales smelting coal.	Waggons, 40 feet fall.	Ventilated	Nearly 2 months	Sulphur in the coal; heated, put into Rio.	Very fine and dry.
Matanzas	660	Wishaw main coal	Partly by hand	Partially ventilated with wood.	2 months	Cause unknown; fire	Fine.
Calcutta	930 part cargo.	- - - -	Waggon spout	Not ventilated	Over 2 months	Ship abandoned.	—
Batavia, Java	1,274	Langley Mill	By hand basket from barges.	Ventilated horizontally on each side of keelson and perpendicularly at each hatchway.	1 month	Bad quality of coal and damp condition.	Fine, a portion of coal taken in wet from barges.
Chili	720	Avon Vale coal (not screened).	Boxes, about 20 feet fall.	Cargo divided into 3 separate compartments.	14 days	Not ascertained; put into Rio and ship sold.	Dry.
Bombay	1,600	- - - -	Waggon, fall 20 feet.	Ventilated	3½ months	Height coals fell in loading; fire.	Showery.
Santos	488	Merthyr Dare, ½ Grovesend, and Gelli and Cadoxton.	By spout	Not ventilated	2 months	Coal fresh wrought, wet, and of fiery nature; ship burnt.	Wet.
Odessa	1,229	- - - -	Spout	Well ventilated.	10 days	Wetness of coal, and possibly proximity to boiler bulkheads; fire extinguished.	Wet.
Chili	650	Smelting coal, Mynhyddy	By boxes	Ventilated	2½ months	Coal small and wet	Wet.
Java	600	Hamilton Coal Co., (double screened).	Wheeled on board.	Ventilated with iron.	3¾ months	No cause attributed	Fine and dry.
Aden	2,087	Insoles Merthyr and Steam coal.	Waggon	Ventilated	16 weeks	Not ascertained; partial damage.	Fine.
Galle	600	- - - -	- - -	Not ventilated	2½ months	No cause known; fire	Dry.
Point de Galle	1,700	Townhill Colliery steam coal (double screened)	Waggon	9 fixed ventilators, besides plank ventilators.	Nearly 3 months	Coal coming fresh from pit; ship abandoned.	Fine and dry.
Constantinople	626	S. & W. Yorkshire pits (double screened).	- - -	- - -	2 months	Wet state of cargo; fire	Raining incessantly.
Calcutta	1,170	Wishaw Ell coal (Lanark district (single screened).	Waggon	Through ventilation.	2¾ months	Ventilation, and wet state of coal.	Very wet.
Rio	750	- - - -	Tips	Ventilated	2 months	Freshness of coal from pits; ship scuttled at Rio.	Fine and dry.
Calcutta	1,955	Ell coal from Lanarkshire.	Waggon	Well ventilated.	7 weeks	Water getting in through side lights.	Wet during voyage.
Bombay	1,441	Cowpen	Waggon, 27 feet run, 26 feet fall.	Fairly ventilated.	Over 5 months	Dampness of coal; fired two days.	Fair, but wind and rain on voyage.
Bombay	1,977	Howard's West Hartley best quality steam (double screened).	By spout	Ventilated	3½ months	Coals too fresh from pits, and not sufficiently screened; ship beached and scuttled.	Average weather.
Bombay	1,664	Howard's West Hartley.	Tips and loading apparatus.	Well ventilated with Venetian shafts.	3 months	No information.	—
Valparaiso	564	Alner smelting coal (unscreened).	Waggon, fall 30 feet.	Ventilated	Over 3 months	Wet state of cargo; fire	Very wet.

TABLE II.

List of Coal-laden Vessels which sailed from the United Kingdom for Foreign Ports during the year 1874 to which Casualties occurred through Spontaneous Combustion in the Coal.

Date of Clearance or Sailing.	Name of Vessel.	Owners.	Flag.	Ton-nage.	How long built.	Wood or Iron.	Class.	Port of Loading.	Port of Destination.	Quantity shipped.	Description of Coal.	How loaded, Barrows or Tips.	Whether ventilated, and how.	How long Coal had been on Board.	Supposed Cause and Extent of Casualty.	Lives lost, so far as reported.	Weather when loading.

---

† This vessel sailed again 31st August from the Tyne for Hamburg with coal, and was published as missing in Lloyds' List of 7th October. In Lloyds' List of 9th September a report appears of a lifeboat belonging to this vessel having been picked up off the Doggerbank, and in Lloyds' List of 10th September there is a paragraph stating that it was reported that an explosion had taken place causing her to founder, and that there were 22 hands on board.

TABLE IV.

This List is made up to July 6th, 1876; but there may be other Vessels posted as Missing during the remainder of the year 1876, which had sailed in the year 1875.

Vessels with Patent Fuel not included in the List.

APPENDIX VI.

Form of Specification for Coal Cargoes.

* Specification (in lieu of Shipping Bill and Customs Bill of lading) for *British and Irish* goods only.†

Port of ____________ In the ship ____________ ____________Master, for ____________

* The Specification of Goods exported must be delivered to the proper Officers of Customs within six days from the time of the final clearance of the ship, as required by the 23 Vict. cap. 22.

† The Goods must be described in accordance with the denomination in the Official List of British and Irish Produce and Manufactures exported.

Marks.	Numbers.	No. and Description of Packages.	Quantity and Description of Goods.	Value.
			Total -	

I declare that the particulars set forth above are correctly stated.

Date ____________ 187 . Exporter or Agent____________ Address ____________

G O $\frac{139}{1870}$ and $\frac{11}{1873}$.

APPENDIX VII.

Selected Correspondence.

(*a*.) Letter from Mr. Charles Icely, R.N., on Combustion of Coal in Plymouth Gasworks.

8 Hyde Park Terrace, Mutley,
near Plymouth, 1st April 1876.

Sir,

In accordance with the wish of the Commission for a report in regard to the case of spontaneous combustion at the Plymouth Gasworks, which manifested itself actively during the month of February last, I beg to submit the following statement as the result of my observation on the spot, together with information given by Mr. Browning, the engineer of the works. There are at these works six coal stores, two of which are severally 116 feet 6 inches long, 66 feet broad, and 26 feet in height, and will contain each 4,750 tons. The remaining ones, which are smaller, vary in capacity. The whole of them will contain in the aggregate 13,000 tons.

On the occasion of my visit the smaller ones were clear of coal, and the two larger (which are contiguous) were about two-thirds empty, but still containing from 700 to 800 tons each, represented by heaps 26 feet in height. The coal in both was in process of combustion, and presented this singular feature, "That the fire was mainly confined " to a stratum about 18 inches wide, and this at a height " of 10 feet from the basement, traversing the heap " laterally, and identical in height and width in both " stores, although a stone partition wall two feet in " thickness divided them." There were inconsiderable patches of fire (if they may be so termed) in other parts of these heaps above this *belt*, but none that attracted my attention at this time below it.

I elicited from Mr. Browning that it had been the custom of the Company for some years past to keep the stores filled up by a continuous supply during the summer months, while freights were low, and that in consequence a great portion of the coal would be stored from five to six months before being required for use. In such case it invariably heated, and year after year it had been his experience, when digging into the mass, to discover combustion more or less advanced. He had observed, too, on these occasions, that in places where the combustion was in its incipient stage the new supply of air rendered by the turning over of the coal soon induced activity.

To show the inertness of water in extinguishing fire of this nature, he drew my attention to isolated heaps of coal in other parts of the store, of from one to two tons, then smouldering, which he assured me had been well damped with water a week previously.

The coals usually bought by the Plymouth Company are of three varieties, viz.:—Peareth, Pelaw Main, and New Pelton. Mr. Browning was of opinion that "Peareth" was in the largest quantity in this case.

The large heaps in which the fire was present were closely lying masses of small coal. A sample was found to be very friable, and largely impregnated with iron pyrites.

Viewing the facts of this case as herein narrated, they appear to be fairly confirmatory of the evidence already before the Commission, viz:—"The danger accruing from " long storage of finely divided coal of certain classes."

"The manifest tendency the so-called through ventila- " tion would have in favouring the development of heat " in such coal," and,—

That water when poured on the surface of a body of coal that has spontaneously ignited, though it may arrest the progress of the fire, does not effectually quench it.

In view also of the tenacity with which spontaneous fire seems to cling to the combustible substance of coal, I submit with much deference, for the consideration of the Commission, that if the contemplated steam experiment for dealing with an artificial fire proves successful, a further trial of its efficacy should be made (if practicable) on a mass of coal under the altered conditions of spontaneous ignition.

I am, &c.
Chas. Icely.

J. M. Carmichael, Esq.

(*b*.) Letter from Professor Ferguson on Chemical Analysis of Coal.

The following is a letter from Mr. Ferguson, Professor of Chemistry at Glasgow University, giving the results of his examination of four samples of coal submitted to him, and at the same time expressing his opinion that conclusions obtained from such limited experiments should not be relied upon.

The samples submitted to him were "Hamilton Ell," "Watson's Ell," "Russell's Splint," and "Roughrigg coal." "Hamilton Ell" and "Watson's Ell," or "Hartley" as it is sometimes called, would represent the cargoes shipped in the "County of Nairn," "Walter Bain," "Isabella Kerr," "Lucayas," "Brenhilda," and "Blair Athole," but it was stated by those supplying the samples that they would show a greater proportion of pyrites than would be found in the mass, although pyrites would be found to a greater or less degree in all Ell coal.

University of Glasgow,
May 16th, 1876.

Dear Sir,

In reply to your favour of the 15th inst., I beg to send you the results of my examination of four samples of coal furnished me by Mr. John Ferguson of Whiteinch. You will observe that I have confined my examination to the general composition of the coals, in so far as that seemed to me to bear on the question of spontaneous combustion. No. 1. is Ell coal from the Hamilton Coal Company: No. 2 is Ell coal from J. Watson; No. 3 is Ell coal from Roughrigg; No 4 is Russell's Splint. The numbers express percentages.

	No. 1.	No. 2.	No. 3.	No. 4.
Moisture - - -	8·15	6·55	1·60	6·30
Ash - - -	19·50	17·20	2·90	7·20
Coke - - -	59·24	55·88	67·10	57·12
Sulphur (total) - -	14·66	10·84	—·809	—·589
Iron - - -	5·68	5·42	Trace.	Trace.
„ pyrites - -	12·17	11·61		

Nos. 1 and 2 accordingly contain much pyrites, indeed the mineral was quite apparent in the coal; Nos. 3 and 4 are practically free from pyrites.

In order to ascertain to what extent the pyrites in the coal undergoes oxidation, I made one or two experiments, with the following resuls. Portions of the coals were taken and the amount of oxidized sulphur (assumed to be sulphuric anhydride—OS_3—entirely) present estimated. The coals were then spread out to the air, one part being kept dry, another being moistened from time to time. Portions of these were taken at intervals and new deter-tions of SO_3 in them made. The numbers again denote per-centages.

——	No. 1. SO_3.	No. 2 SO_3.	No. 3. SO_3.	No. 4. SO_3.
In original sample at 21st December 1875.	—·198	—·218	Nil.	Nil.
After exposure, moist, till 21st January 1876.	—·280	—·346	—	—
After further exposure till 24th January 1876.	—·308	—·390	—	—
After exposure, dry, till 21st January 1876.	—·311	—·307	—	—
After further exposure till 24th January 1876.	—·342	—·350	—·034	—·099

A portion of No. 2 was also kept in air for a week at a temperature of 104° Fahr., at the end of which time the SO_3 amounted to —·548.

These numbers, if they are of any value at all, (for in an experiment on so small a scale and for so short a time the smallest accidental circumstance might produce considerable variations and anomalies, which could be got rid of only after many repititions,) show that the oxidation was most rapid at first. Thus No. 1 in the dry state increased at first from ·198 to ·311, that is, by ·113; afterwards it increased from ·311 to ·342, or by ·031 only, and similarly with all the others. It is observable that No. 1 moist oxidized less rapidly than when dry, whereas No. 2 oxidized at first more rapidly than when dry. The results therefore with regard to dampness of the coal are contradictory. The oxidation of the pyrites appears to go on slowly and at a diminishing rate. The only other inference that forces itself upon us is, that if all four are samples of coal which have caught fire spontaneously, it can hardly have been due to the oxidation of pyrites alone, seeing that No. 3 and 4 are free from that substance.

My opinion is that conclusions of any worth could be arrived at only after very many experiments on different kinds of coal, placed under varying conditions of temperature, &c., and that great care is requisite in interpreting the results of two or three experiments like the above. The next point to examine is the extent to which the carbon and hydrogen of the coal itself undergo slow oxidation, and whether spontaneous combustion be not due to that action.

I am, &c.

J. M. Carmichael, Esq. JOHN FERGUSON.

(c.) LETTER from MR. POOLE, INSPECTOR of MINES, NOVA SCOTIA.

Halifax, Nova Scotia,
January 12th, 1876.

SIR,

IN accordance with the request conveyed in your letter of August 3rd, 1875, I have the honour to forward you the following information on the subject before the Commission, to be submitted, should it meet with your approval, before the Royal Commission on the Spontaneous Combustion of Coal at Sea.

I am happy to be enabled to give, besides the results of my own observations, information bearing on the subject from several gentlemen of the United States. I am more particularly indebted to Estes Howe, Esq., M.D., President of the Cambridge Gaslight Company, for his assistance in obtaining the opinions of others. He has sent me the accompanying paper (I.) read before the New England Association of Gas Engineers, in February 1875, by J. H. Armington, Esq., Superintendent of the Brooklyn Gas Company.

II. A statement, with a diagram, from Mr. Lees, President of the New York Gas Company.

III. A letter from the Hon. Knowlton S. Chaffee on the Spontaneous Combustion of Charcoal.

IV. Is Dr. Howe's own statement.

V. A statement of R. C. Adams, Esq., of Montreal, on the heating of Nova Scotia coals in the sheds at Montreal and Quebec.

VI. A letter from W. W. Greenough, Esq., Treasurer of the Boston Gaslight Company, on the Spontaneous Combustion of Albertite.

On my own part, I will first refer to the coals of this province, which are all bituminous, and which may be classified according to the two chief districts in which they are mined, Pictou and Cape Breton, into non-caking and caking coals. The following analyses may be taken as typical of their composition:—

	Pictou.		Cape Breton.
Volatile matter	- 30·48	-	33·44
Fixed carbon	- 61·23	-	62·32
Ash -	- 8·29	-	4·23
	100·00		100·00

The per-centage of sulphur in the Pictou coals varies from ·26 to 1·68; an average of seven analyses gives ·72 per cent. The quantity contained in Cape Breton coals is greater; an average of fourteen analyses gives 2·05 per cent. of sulphur.

The Pictou coals are harder, and stand handling and transportation better than those of Cape Breton. They are chiefly used for steam purposes, and so far as is known they have never heated, either in store or on board ship. The quantities exported south of the equator have been very small: 4,388 tons in 1874, 753 tons in 1873, and 1,600 tons in 1875. Large quantities have, however, been stored for months in the chief towns of New England, and in Montreal and Quebec, and in no case is the coal known to have heated to any extent.

The same cannot be said of the Cape Breton coals, which are more friable than those of Pictou, and cases of spontaneous combustion are known to have occured with some of these coals. They are nearly all caking coals, and suitable for gas manufacture, though many or all find some service as steam and domestic coals. The quantities sent south of the equator have been small: 1,132 tons in 1873, 688 tons in 1874, and 3,446 tons in 1875.

A cargo of 1,000 tons, unventilated, arrived in good order at Singapore.

The general practice of the country during the winter months, when the ports are closed and shipping prevented by ice, is to bank the coal mined in heaps of ten, twenty, and even forty thousand tons, to a height of 18 to 25 feet. In no case has heat been known to have been generated in these banks, although some of them have not been all lifted until late in the autumn. As a confirmation of the absence of a great increase of temperature, it has often been noticed that when the coal has been negligently dumped over snow, ice is found in the heap even late in the summer. As, however, many coals so heaped do slack even in the centre of the banks, I suspect a slight increase of temperature does take place at some period. I shall suggest that tubes be inserted, and the temperature at several places in some heaps be taken and compared with the average of the atmosphere. At some mines the coal banked is first riddled in the pit, at others the duff is not removed, and the opinion of some managers is, that the per-centage of screenings is as large from that which has been riddled as from that which has not been riddled; in other words, that the deterioration is diminished by leaving the duff with the coal. Heating has been observed in piles of slack coal that have been accumulated during the summer for the use of the engines during the winter, when the season has been showery, but not when it has been dry. A pile of 3,000 tons of coarse coal of the same seam was kept in sheds for three years without heating. A heap of screenings 19 feet high, 250 feet long, and averaging 33 feet wide, collected within a couple of months, took fire within two months after being completed. Smoke was first observed on the side of the heap some 6 feet from the bottom. On shovelling away the surface layer, 6 inches thick, a crust a foot in thickness was found underneath, which, on being disturbed, broke into flames. A similar heap on drier ground, but four times as long, and slowly accumulated, never heated.

A cargo of coal from another seam which has never heated in the pit banks, was discharged on a wooden wharf at Boston, where air played over, under, and round it, and took fire within a very few weeks.

Mr. Adams, in Appendix V., describes the circumstances of cases of spontaneous combustion at Montreal and Quebec, and shows that fires occurred in positions similar to both the cases mentioned by Mr. Armington, at Brooklyn and Troy, in the fine, compact, and damp coal directly under the dump, and in the coarse coal with freer ventilation, as Dr. Howe confirmed in his statement. Mr. Lee's diagram shows how very local the origin of a fire may be, and Mr. Armington mentions a similar case, though it is evident there is at the same time a general elevation of the temperature of the mass. Dr. Howe and Mr. Armington agree that the best American gas coals, containing less sulphur than our provincial coals, are just as liable to spontaneous combustion. Messrs. Perkins and Job of Boston and New York, who have been in the coal trade for over 30 years, hold similar views, and further state that they do not know of one case of fire at sea in a vessel laden with Nova Scotia coal. The heating of the Cumberland coal of Maryland in the dockyard of Halifax, and its ignition at Bermuda, prove that that that excellent steam coal is not free from danger. The heating of the albertite, which is entirely free from sulphur, was thought to be due to the absorption of oxygen, as in the case of charcoal, but a doubt has been raised since it has been shown that 5 per cent. of the shipments consist of bituminous shale (the walls of the vein from which the albertite has been extracted by heat and pressure), which are said to contain a small per-centage of sulphur. The percentage, however, is so small that it is hardly sufficient to account for the general heating observed.

The loss of the barque "Senator," in October 1875, was stated to be due to the spontaneous combustion of semibituminous coal, but inquiries disclosed that besides the 1,200 tons of Broadtop semibituminous coal, she carried 400 tons of small Charfield bituminous, which was taken on board in wet weather. She was ventilated. Respecting anthracite, Major Morris, of the Reading railway, writes, he has loaded a large number of vessels up to 2,000 tons capacity with anthracite for Chili, San Francisco, Japan, &c., and in no case were precautions taken or proved to be in future necessary. The Hon. S. Sloan, President of the Delaware, Lackawanna, and Western Railway confirms the opinion that there is no necessity for care against fire with anthracite. Dr. Howe, in his statement, points out the opinion of the workmen, that all coal heaps pass through a heating process. I would remark in connexion with this, that this stage must be slight in the heaps of fresh mined coal, as it has not hitherto been noticed, but that it appears to be developed when the coal is turned over and wetted, just as heaps of pyrites and decaying vegetable matter. Regretting that the information on the matter at my command is not more specific and relevant in character,

I have, &c.
HENRY S. POOLE, M.A., F.G.S., &c.
Inspector of Mines for Nova Scotia.

The Rt. Hon. HUGH C. E. CHILDERS, M.P.,
Chairman of the Royal Commission
on the Spontaneous Combustion of Coal at Sea.

I.

A PAPER read before a MEETING of the NEW ENGLAND ASSOCIATION of GAS ENGINEERS, February 1875, by Colonel J. H. ARMINGTON.

During the month of December 1874 it was discovered that the coal stored in the coal sheds of the Brooklyn Gaslight Company was on fire. It has been the practice for many years at these works to introduce gas tubing, 1½ inches in diameter, in the various piles of coal, in order that the temperature should be known, and a daily record made of it. In this way a careful watch has been kept, and whenever the temperature changes it has been immediately noticed, and the necessary steps taken to prevent further danger, by at once using the coal showing the extra heat. The coals purchased by this Company during 1874 were supposed to be so free from sulphur and iron that the tubing was not introduced, and consequently the high temperature was not known until that particular odour was noticed which is always given off when spontaneous combustion occurs in gas coals. At the same time that the peculiar odour was apparent, smoke appeared in the shed, and operations were at once commenced to find the fire. After three days and nights of continual labour, and the removal of about 900 tons of coal, the fire was discovered to have taken place in a pile of Penn coal; and, when reached, it proved to be confined to a space of less than 12 feet in diameter and 4 feet in height. The entire mass was so thoroughly baked together that it had to be broken in pieces with bars in order to remove it. After removing it from the shed it was piled in a heap on the wharf, and in a few minutes after being exposed to the air the whole mass was in a blaze. Only two instances of this kind have ever come to the knowledge of the writer, of spontaneous combustion in our domestic coals; and I believe it is the general opinion of gas engineers that no danger is to be apprehended from stowing these coals in piles of the ordinary height that we are accustomed to see about the gasworks in this country.

The first instance of this kind that came to my knowledge occurred in Troy, N.Y., and the cause was said to have been from its being so solidly packed, the fire having taken place directly underneath the dumping hatch of the coal shed. The other was in the works of the New York Gas Company, and the cause of this fire I have never heard stated. The fire in the shed of the Brooklyn Gas Company commenced between the tracks, and in that portion of the coal which rolled from the piles when it was dumped, on each side of it; it must therefore be evident to us all that this fire could not have occurred from the same cause as that mentioned in the coal sheds at Troy.

From whatever cause the fire did proceed (and in this case I am unable to give any satisfactory reason for it), it shows us that there is danger of spontaneous combustion in our coal stores, and that the necessary precautions should always be taken to discover any overheating which may be likely to recur. Having been asked how the pipes are prepared in which the thermometers are inserted, I will state, that in one end of a pipe a solid pointed plug is welded to close the end and to better adapt the pipe for being driven down through the coal; above this plug a dozen or more holes, ½ inch in diameter, are then drilled, giving the necessary openings for the air to enter.

The temperatures, which are taken regularly, vary from day to day, and are always found to be higher than the atmosphere. By an examination of the tables of temperature accompanying this paper, it will be seen that this variation is very great, and proceeds from some cause which is well worthy of our consideration.

During the past week it was discovered that the temperature was rising in a pile of Newcastle coal, and when the thermometer indicated 200° men were set at work to turn the coal over, and the fire was found in one of the spruce uprights which supported the trestlework of the track from which the coal was dumped. This coal had been piled about seven months, and the fire was directly under the track from which the coal was dumped. The fire was confined to a space about 8 inches in diameter, and had not, so far as could be discovered, affected the coal except by disintegration. It will be noticed in this case that the heat was sufficient to ignite the wood, and had it not been discovered, the burning of the wood would have ignited the coal. The high temperature that had been noticed in this pile of coal previous to the discovery of the fire was 120°; and while the coal was being removed, another thermometer, within 10 feet of the one indicating 200°, only indicated 118°.

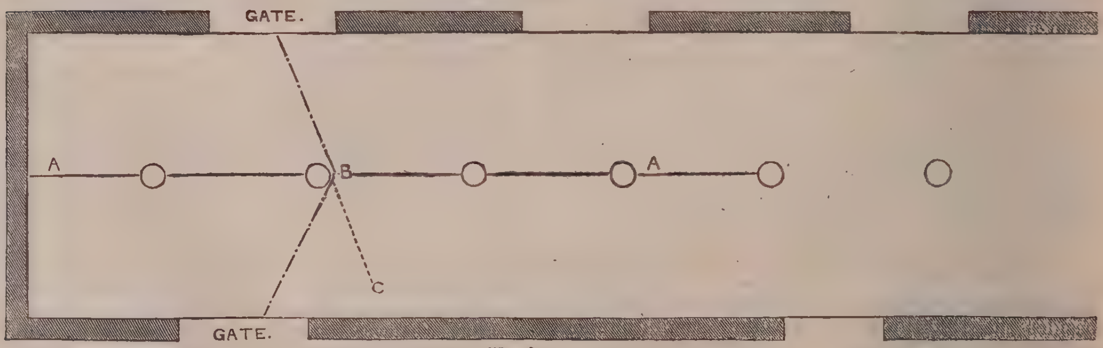
II.

A STATEMENT made by MR. LEES, President of the New York Gas Company.

21st Street.



Yard.

STATEMENT from New York Gas Company.

A A is a wooden partition to separate coal.

Over B is an open ventilator in the roof through which the smoke was first seen. The gates in the yard and on 21st Street were opened and the coal removed to B (see red dots), where the partition was found charred and burning at about 15 or 20 feet from the ground. The fire was then traced from B to C (see black dots), growing deeper all the way, until at C it was found in the form of a red-hot coke on the floor. There was no wood at or near C. Nor was any burned except on the partition at B. The floor is of stone.

The whole quantity of coal burned did not exceed (say) 30 tons, of which the centre, C, was thoroughly carbonized.

The coal was Penn and Westmoreland mixed and had been in about six months.

III.

On the SPONTANEOUS COMBUSTION of CHARCOAL, by the HON. KNOWLTON S. CHAFFEE, of Boston.

In answer to your questions on the spontaneous combustion of charcoal I will say, First, that I have been engaged in the business about 30 years, and have annually handled nearly a million of bushels. Second, the coal is made at all seasons of the year, and chiefly burned in brick-kilns. Third, the Boston market requires that the coal shall be free from dust, therefore it is screened over half-inch mesh screens. The screenings if dry and piled in heaps of 100 bushels or more, whether on the ground or a floor of any kind, either under cover or outside, will heat and produce spontaneous combustion in a very few days. The heat will extend through the whole pile. You ask, whether wet or dry? Of course if very wet it cannot heat, and if perfectly dry it would not as long as it remained so, but it will inhale moisture enough from the ground and atmosphere to produce heat; and if in a large pile, it will bear several heavy showers before it would become wet enough to prevent heat, as the water would not penetrate sufficiently through it. There is no danger of regular charcoal heating, as its size will admit the circulation of air. If pulverized to a fine powder it will be so solid that it cannot heat, but the screenings to which I refer, when dry, will heat under almost any circumstances.

Coal burned in pits the old-fashioned way, covered with earth, never troubled us, and I do not believe will heat.

IV.

STATEMENT of ESTES HOWE, ESQ., M.D., President of the Cambridge Gas Company.

* * * * In November 1873 a spontaneous fire occurred in the coal shed of the Cambridge Gaslight Company, Massachusetts. The shed is of wood, 300 feet long, 70 feet wide, situated on a wharf, and receives the coal directly from the vessel. The coal is hoisted to the height of the run which extends the whole length of the building through the middle, at a height of 22 feet. The floor at this time was of earth. The coal affected was a mixture of Glace Bay and Caledonia, Nova Scotia coals. The run is supported by posts of spruce 10 inches square and 10 feet apart each way. The coal had been put in rapidly and was all dumped from the run. It was thought to be finer than usual, and probably more damp. There was some idea that rain had blown in through the hatchways and dripped down at the place affected. This is not certain. The fire was first indicated by steam and smoke escaping. Thinking the trouble might be superficial, men were put on to shovel the coal over, but at one point, at which one of the posts was the centre, it was found that the heat increased on going down. At a point about five feet from the surface the post was completely converted into charcoal, and that without any appearance of redness, no live fire being found for two or three feet below this point. The coal surrounding the post was agglutinated, and in the first stage of coking. The fire was followed down to the floor, and a very large quantity of coal was removed. At a point about 20 feet distant, around another post, the same heating, though to a less degree, occurred. Some heating in the upper part of the coal heap at a point nearly 200 feet distant was also observed, but shovelling over about four or five feet of the top put an end to it. A similar difficulty occurred in a pile of Cape Breton coal in August of this year. It was early discovered, and was confined to a limited space directly *under the dump*. The coal was fine and closely packed, and possibly unusually damp. There was no post or other wood concerned in this case. Nor was there any tendency to heat shown in the rest of the coal. For many years I have noticed my coal piles showed a tendency to heat, and I have had to remove coal which otherwise I feared would ignite.

I have visited the Brooklyn, New York, and Manhattan gas works, and have made inquiries of many in relation to the matter of spontaneous combustion. I find that it has taken place in charcoal, albertite, Newcastle coal, all Cape Breton coals, and all trans-Allegheny coals, that is, in Penn, Westmoreland, Youghiogheny, Newburgh, Orrel, Fairmount, &c. The first three are taken from the Pittsburgh main seam at different points, and they are the purest and best American gas coals. In every case, except one at the Manhattan, the coal affected was fine and very closely packed. In many, but not in all cases, the trouble seemed to originate where the coal was dumped.

My own observations have led me to think that a certain process of heating in piles of coal is very general, if not universal. The observations of Mr. Armington, by means of gas pipes driven down through or placed in the coal as it is stored, confirms this idea, and the engineer of the Manhattan gasworks makes the same statement. Mr. Armington has in his coal shed, which is 210 by 180 feet, and now stored 22 feet deep with coal, mostly American, 60 of these tubes, with thermometers in them, of which a daily register is kept, As having a bearing on this matter I give you some figures from his register. The tubes are numbered. A group of tubes quite near each other, numbered 1, 2, 3, 4, were placed at a point which seemed hot, which was filled 14 feet deep, and the filling discontinued on account of the heat.

PENN COAL.

1875.

No.	Oct. 13.	Oct. 14.	Oct. 22.	Nov. 13.	Nov. 30.
	°	°	°	°	°

FAIRMOUNT COAL.

	118	118	112	56	56
	106	106	102	62	58
	102	102	100	70	56
	98	98	90	52	62
	90	88	92	54	64
	86	84	84	56	70

I would add that the labourers in the coal sheds all agree that the coal heaps go through a heating process, and when that is once over they think it does not recur.

There is a very general impression that the presence of wood leads to spontaneous combustion. It seems to me that this impression arises from the fact that wood, especially all varieties of fir, ignites at a much lower temperature than coal, and if coal is heated in the presence of wood, the wood first takes fire.

I may add that my experience shows that if air is excluded the process of combustion in the compact heap of coal is slow, and time may be taken. I have yet to hear of a case where there was a general heating to the blazing point of a pile of coal. There seems to be a nucleus of heated coal, which gradually extends upwards, spreading as it rises. When, however, any considerable quantity is heated, gas is given off, which coming to the air may be lighted and burn rapidly.

It seems to me that the plan of observations of temperature by means of gas tubes in the coal is easily applicable to coal on board ship, and would afford most valuable information of the condition of the cargo.

V.

STATEMENT of ROBERT C. ADAMS, ESQ., of Montreal.

The Nova Scotia coals imported in 1873 by the Grand Trunk Railway were piled in open spaces in three localities. One pile, all of Cape Breton coal, of 12,000 to 15,000 tons, another of 12,000 tons, chiefly of Cape Breton, and the third chiefly of Nova Scotia (Pictou) with some Cape Breton. Much of the coal was wet when piled, for the season was rainy. Late in the fall, when the coal had been two or three months in yard, the two piles consisting of Cape Breton coal were discovered to be on fire, and the third smoked. The coal was dug through, turned over, and the fire extinguished by this means. Water was also used freely, but without much effect. The coal was very fine. The third heap did not ignite.

The gas company last winter had about 9,000 tons of Cape Breton coal stored quite dry in a covered building, piled 12 to 14 feet high. The coal was small. After being stored five or six months fire broke out among the larger sized coal that ran out to the walls, and against the posts supporting the roof. The fire ran up the posts, ignited the roof and the platforms over the coal. This caused the whole surface of the coal to catch fire, and it burned to a depth of 2 feet, being finally extinguished by water. The fire below was subdued by digging through and carting away the coal. It was found that among the small coal in the centre of the pile there was no fire. This causes the engineer to think that ventilation assists combustion, the fire having burned in the large coal where there was the most circulation of air. The Grand Trunk Railway adopting the opposite theory, have placed ventilating platforms and chimneys through their coal heaps.

An illustration of the danger arising from wet coal is furnished by a vessel lately arrived with Cape Breton coal. She loaded in the rain, and the wet coal under the hatches was nearly in a state of combustion, while the drier coal in the ends of the vessel was cool.

VI.

Office of the Boston Gas-Light Company,
No. 24, West Street, Boston,
30th Nov. 1875.

DEAR SIR,

WE have been purchasers of Albert coal for more than twenty years, and during the larger proportion of that time have received a very considerable share of the products of the mine.

The published analysis of the coal shows an entire freedom from sulphur.

It has usually been stored by us in large sheds, and piled to a height of twenty or more feet. Latterly, it has been piled in the open air, without any protection from the weather.

During the period of time that we have had the coal, it has heated four times—but more seriously during the autumn of 1874 than ever before. On two seasons before this, it heated and fired the timber supports of the shed in which it was stored, for which no explanation at the time could be found.

Last year a special examination of the coal was made for the purpose of ascertaining the cause. It was found that a certain portion of the lining of the mine, as well as the seam in the coal, contained pyrites. Thin shale formed about five per cent. of the mass, and with the disintegrated condition of the coal, being mostly of the description called "slack" at the mines, sufficient elements were found to account for heating, fusion, or even fire.

The following analysis, Dr. S. Dana Hayes and Prof. P. Sterry Hunt shows the effect of "heating":—

	Albert coal of good quality.	Albert coal after "heating."
Bituminous and volatile matter	56·05	4·65
Coke	40·81	85·89
Ash (red and mostly oxide of iron)	3·14	9·46
	100·	100·

Whenever the coal showed symptoms of heating, it was shovelled over in the heaps for the purpose of cooling it.

Yours respectfully,
W. W. GREENOUGH.

Henry S. Poole, Esq.,
Inspector of Mines,
Halifax, Nova Scotia.

(d.) PAPER and STATISTICS from the ROYAL MAIL STEAM PACKET COMPANY.

THE following information and statistics were furnished by the Royal Mail Steam Packet Company with reference to the Inquiry of the Commission.

Royal Mail Steam Packet Company,
No. 55, Moorgate Street, London, E.C.
16th November 1875.

SIR,

I AM instructed by Mr. Marshall to forward you the following documents which you wished to be furnished with for the information of the Royal Commission on the Spontaneous Combustion of Coals, viz., Copy of instructions to superintendents at ports of shipment; Table showing the description, quantities, destination, &c., of the various shipments for the Company during the last three years; and I will be glad to furnish you with any further information you may wish for the information of the Committee.

I am, sir, your obedient servant,
T. C. W. DYER,
pro Secretary.

James Carmichael, Esq.,
32, Abingdon Street,
Westminster.

Royal Mail Steam Packet Company.

Instructions for Mr. Pope, Coal Inspector.

1. By accompanying form, marked No. 1, you will observe that all coals purchased by the Company should be of the best quality, and fresh wrought; and it will be your duty to see that the coals shipped are the produce of the mines and of the description stipulated for. Moreover, that all conditions of purchase are duly fulfilled. In order that you may have the necessary power to ascertain this, you have permission to examine the pit-head tally books at all times, and you will be duly advised of all new contracts.

2. The loading of each vessel must be personally superintended during the shipment.

3. Each vessel must be examined before receiving stiffening to see that the hold is properly prepared and cleaned to receive it, and that the coals are kept strictly clear of the ballast, which, if of sand, is injurious to them.

4. The vessel to be again examined when totally unballasted to ensure the hold being clean throughout.

5. The weight of the coals at the tips to be carefully superintended and checked, and subsequently compared with the colliery weights, the result to be reported on Form No. 2, and it is important that the weighing machines at the tips should be tested as to their correctness as often as opportunity arises.

6. In cases where the coals have to be screened at time of shipment, it must be seen that this is properly done, the screens kept open and in no way choked up with the small. The small coal to be drawn, weighed, and properly allowed for.

7. A check must be kept of the tares on the coal waggons, as differences have been frequently found to exist between the weights painted on them and the actual tares. Care must be taken that this is not done in dry weather, and you can exercise your own discretion as to the mode and time of doing this. You will find a memo. marked No. 3, showing how the weights are recorded and the averages arrived at in cases of this kind.

8. The Alexandra Docks at Newport being fitted up with tips and weighing machines, it is preferable that the ships chartered by the Company should load there, and if possible under those tips having anti-breakage boxes. You will see that the latter are always used at first to convey the coal easily into the hold, and, in conjunction with this, that the staith is lowered sufficiently, or as much as possible into the hold, and so prevent much breakage.

9. Although the Company undertake to load the vessels chartered by them in a certain number of days, it must be understood that the contractors hold them harmless in this respect (see Form No. 4), and in case of any question of this kind arising the captains must be referred to the contractors for a settlement, but the facts are nevertheless to be fully reported to the secretary.

10. When a ship is chartered, copy of the charter-party will be at once sent you, and no coals are to be shipped (except those required for stiffening) until the ship be wholly unballasted and ready for cargo, when the loading days may be said to commence, supposing the ordinary notice for cargo has been given to the contractors.

11. You will carefully ascertain what coals the vessel has on board (if any) previous to cargo being shipped. This should be kept apart, and made up to one per cent. of cargo. Should the captain have any wood on board it can stand against a proportionate quantity of coal, if you think it advisable.

12. Bills of lading are issued on the Company's form, No. 5, in sets of four; two of which are to be sent to the Company's office, one by the ship for the Company's agent, with the copy of charter-party, and the other for the captain. The captain must sign for the cargo on the bills of lading as per dock or railway weights.

13. The captain must sign (on the back of the bills of lading) for the advance which will be paid in London in terms of clause in charter-party. Great care is to be taken in calculating the freight, which is to be inserted on the bills of lading, deducting the advance if any. It is seldom more than one third of the freight is advanced, but in no case (unless with the Company's sanction) is the advance to exceed the amount stated in charter-party. The captains can, however, take what lesser amounts they choose, provided the same be not lower than 50*l.*, except in cases of very small ships.

14. A form of certificate, No.   , is to be filled up for each vessel which may be loaded, and sent to the Company's office with the bills of lading. On the back of this certificate the colliery and tip weights are to be inserted, also the quantity of small extracted, which deduction from the tip weights would, in the case of double-screened coal, form the bill of lading quantity.

15. The contract for coals required at Southampton has been made with Messrs. D. Davis and Sons for their double-screened Merthyr coal. A steamer is sent by Messrs. Wm. Hill & Co. about once a week for these supplies, and the Company pay for the same in accordance with the *delivery* weight at Southampton. It is, however, necessary that in addition to the usual inspection you should ascertain the quantity shipped, and inform the Company's superintendent at Southampton (Captain Bevis) immediately a steamer is loaded of the quantity she has on board.

16. A daily report (No. 6) should be made to the Company stating the quantity of coals shipped during the day, vessels in port when stemmed for cargo, and all other information which you may consider the Company should be acquainted with. It would be interesting also if you stated any information you might glean about new

pits being opened, alterations in wages, strikes, &c. of colliers.

17. Before the invoices for coals are sent to this office for payment they should be certified by you as correct.

18. You will send a note of your travelling expenses to the secretary monthly, as well as a note of your salary, a cheque for which will be sent to you.

19. A demand is to be forwarded to the secretary every three months for all stationery required, and the supplies will be sent from the Company's printers. Samples of same are to accompany your demand, but in case you should have to purchase any stationery, &c., a receipted invoice for the same is to accompany the monthly account.

20. The Company's agents at their coaling depôts are:—

Lisbon -	Messrs. R. Knowles & Co.
Cape de Verds	Messrs. Millers and Nephew.
Rio de Janeiro	Thomas Hollocombe, Esq.
St. Thomas -	J. B. Cameron, Esq., Superintendent.
Jamaica -	Captain Dix, Superintendent.
St. Lucia -	F. Peter, Esq.
Colon -	J. H. Leverick, Esq.
Havana -	J. V. Crawford, Esq., H.B.M. Consul.

The only known case of coals heating or taking fire on board or in stores took place at Cape de Verds in 1873 amongst a heap of Coed Talon and Bryn Mally coals.

(e.) PAPER and STATISTICS from the PENINSULAR and ORIENTAL STEAM NAVIGATION COMPANY.

The following information and statistics were furnished to the Commission, with reference to their Inquiry, by the Peninsular and Oriental Steam Navigation Company:—

MEMORANDUM relative to SPONTANEOUS COMBUSTION of COAL on SHORE, and in BUNKERS of the COMPANY'S STEAMERS.

Cases of spontaneous combustion in the Company's coal stacks have taken place, but taking into consideration the heavy stocks kept up, and the extremes of heat and moisture to which they are exposed, such instances are very rare.

About 10 years ago a case of firing occurred near the bottom of a large stack of coal at Calcutta, when about a thousand tons of coal had to be removed; it was then discovered that for a space of about six feet square the coal was in a very heated and charred condition.

At Aden, in July last, two cases of heating occurred, one in the heart of a stack of North Wales coal, and the other near the surface of a heap of Bebside Hartley (Newcastle) coal.

In the course of the last 10 years three or four cases of explosion in the bunkers of the Company's steamers have taken place owing to the *close* covers of the bunkers having been kept on too long; it is, however, one of the Company's standing orders to their chief engineers, that "the close "covers of the bunkers must only be put on when the "decks are being washed, or in very bad weather, *grated* "covers being used on all other occasions, so as to permit "of the escape of the gas generated in the coals."

(For the same reason it would be well were the hatches of colliers lifted on all occasions where practicable.)

In the Company's experience, cargoes of the South Wales coal are much less liable to spontaneous combustion than either Newcastle or North Wales coal.

The arrangements for stacking the Company's coal are as follows:—

Malta -	- In sheds in the open, and in barges ready for shipment.
Brindisi -	- In the open.
Aden -	- " "
Bombay -	- Under sheds.
Calcutta -	- " "
Galle -	- In sheds and in the open.
Singapore	- In sheds.
Hong Kong	- "
Shanghai	- "
Yokohama	- In floating hulk, and in sheds on shore.
King G. Sound	- In floating hulks, and in the open on shore.

P. & O. S. N. Company, London,

(*f.*) PAPER and STATISTICS from the MERSEY DOCKS and HARBOUR BOARD.

STATEMENT as to the SHIPMENT of COAL at the BOARD'S HIGH LEVEL RAILWAY, LIVERPOOL, and at the BOARD'S APPLIANCES, BIRKENHEAD.

DEAR SIR, Secretary's Office, Liverpool, May 15, 1876.

REFERRING to my letter of the 25th ultimo, the statistical information in relation to the shipment of coal at this port, which has been prepared on the suggestion of the Chairman of the Traffic Committee, is now complete, and I am instructed to hand you the enclosed returns, &c. containing the same, for the use of the Royal Commission.

I am, &c.
EDW. GITTINS,
Secretary.

J. M. Carmichael, Esq.,
Secretary of the Commission on the Combustion of Coal at Sea,
32, Abingdon Street, London, S.W.

SUMMARY OF INFORMATION.

1. List of Vessels and Lighters loaded from January 1st, 1875, to December 31st, 1875.
2. Time loading.
3. Weight and carrying capacity of Waggons.
4. Appliances, capacity of.
5. Rules, Regulations, and Charges.

——	Board's High Level Railway, Liverpool.	Board's Appliances, Birkenhead.
No. 1. LIST OF VESSELS AND LIGHTERS LOADED.	Vessels. See Table A. Lighters. See Table C.	Vessels. See Table B. Lighters. See Table D.
No. 2. TIME LOADING:		
(*a.*) Time required to take in each waggon of coal, say from the time the waggon is hooked to the crane until the coal is tipped down the hatch.	Two minutes	Three minutes.
(*b.*) Quantity per hour that can be loaded into one ship, per crane or hoist.	100 tons per hour per crane, at the quickest speed.	180 tons per hour per hoist is the maximum quantity.
(*c.*) The largest quantity of coal shipped into one vessel per day.	600 tons in one day of 8 working hours.	608 tons, maximum quantity shipped at one hoist in one day of 12 working hours.
No. 3. WAGGONS:	Tons. cwts.	Tons.
Weight of the largest waggon that can be discharged by the appliances.	12 tons gross— Weight of waggon about 4 5 Weight of coal 7 15 12 0	15 tons gross. Weight of waggons 5 Weight of coal 10 15
No. 4. APPLIANCES:		
Capacity of appliances to ship per day of 12 working hours, if fully supplied with coal and ships.	2,200 tons per day	The maximum work done at the coal appliances has been given above (see No. 2), but the speed of tipping being dependent upon the trimming, and taking into consideration the class of vessels that load here, 350 tons of coal per day of 12 hours is a fair average work for each hydraulic tip, which will give a daily shipment by the three tips of 1,050 tons, equal to 326,550 tons per annum. The five hand tips are capable of loading 2,500 tons of coal per day of 12 hours, equal to 777,500 tons per annum.
No. 5. RULES, REGULATIONS, AND CHARGES:		
(*a.*) Rules and Regulations, and Charges.	Copies herewith. See Printed documents marked E. and F.	——
(*b.*) Regulations	- - - - -	See printed document marked G.
(*c.*) Charges	- - - - -	See written statement marked H.

October - - -	394	52,356
November - -	396	51,911
December - -	501	64,244

STATEMENT as to the QUANTITY of COAL SHIPPED by the BOARD'S APPLIANCES at LIVERPOOL and BIRKENHEAD, &c. for the Year ending the 31st of December 1875.

By the Board's Appliances, Liverpool, High Level Railway:—

	Tons.
By hydraulic cranes into ships and flats -	363,433
By hand tip into flats - - -	73,504
Total - - -	436,937

By the Board's Appliances, Birkenhead:—

	Tons.
By hydraulic tips into ships and steamers	77,479
By hand tips into flats and lighters -	579,175
Total - - -	656,654

NOTE.—The under-noted was shipped during the same period by other methods, viz.:—

	Tons.
By railway company's hand tip into flats and lighters - - - -	174,402
By licensed stevedores by barrow into sailing vessels - - - -	254,756
Total - - -	429,158

1867 to 1871	743,000	297,000	1,040,000

E

REGULATIONS to be observed in the loading of Coal and discharging of Ballast at the Coal Tips, Low Level, and Ballast Crane, at Birkenhead.

1. All vessels intended to be loaded with coal shall be berthed in the order in which they are booked for berths at the dock master's office, provided, however, that no coal agent shall load more than one vessel at the tips at the same time, if any other agent requires a berth.

2. No vessel shall be berthed until a certificate is lodged at the dock master's office, that there are fifty tons of coal ready for immediate shipment at the low level berths, and one hundred tons at the tips.

3. Until vessels in berth shall have discharged their ballast, the minimum quantity of coal shipped, or of ballast discharged, shall be one hundred tons as the average, daily at the low level, and two hundred tons at the tips; and

afterwards, the average minimum quantity of coal shipped daily at the low level shall be one hundred and fifty tons, and at the tips two hundred and fifty tons.

4. Vessels not complying with these regulations will be immediately removed from the berth, but will be entitled to the first vacant berth on having the required quantity of coal to proceed with their loading.

5. Vessels in ballast intending to load by the coal tips to take precedence at the ballast crane; and vessels intending to load coal for stiffening to have the use of the crane in preference to vessels to be loaded with an entire cargo by the crane.

6. The use of No. 2 tip is not to interfere with the working of Nos. 1 and 3 tips when the latter are being used by large ships.

By Order of the Board.

Dock Office,
26th September 1867.

F.

SHIPMENT of COAL and DISCHARGE of BALLAST, &c. at BIRKENHEAD.

Secretary's Office,
Liverpool, December 9th, 1874.

The Mersey Docks and Harbour Board are prepared to ship coal and discharge ballast at their hoists, hand tips, and ballast crane, at Birkenhead, also to move, under their regulations, vessels using the appliances in the west float, at the following rates, viz:—

COAL.

	Per Ton.	
	s.	d.
1. For loading coal into ships or steamers, by the hoists, including haulage of wagons, tipping and stowage, and the lowering of ten per cent. of the registered tonnage into the hold at the commencement of loading to avoid breakage - - - - -	0	5
2. Ditto for the bunkers of steamers, by the coal hoists - - - - - - -	0	7½
3. Ditto ditto, by hand, from wagons on the quay - - - - - - - -	1	1
4. Ditto into flats, by tips - - - - -	0	3
5. Ditto into steam barges or steam lighters, by hoists or tips - - - - - - -	0	3
6. Ditto for stiffening, if desired, by the ballast crane, into vessels discharged by the crane, to the extent of ten per cent. of the registered tonnage - - - - - - -	0	6
7. Ditto by the ballast crane, and trimming an entire cargo, or any excess over ten per cent. of the registered tonnage - - - -	0	8
8. Ditto into flats by the ballast crane - -	0	6
9. If weighed by the Board's weighing machines	0	0½
For loading, by the appliances, coal for home consumption (in addition to the above rates) - - - - - - -	0	2

NOTE.—For the shipment of coke double the above rates will be charged.

BALLAST.

	Per Ton.	
	s.	d.
10. For discharging ballast from ships or vessels by the hydraulic crane - - - - - (One tub of ballast in every ten to be weighed on one of the Board's weighing machines.)	0	6
11. Ditto by hand, when the cranes are not available, ballast from vessels berthed at the appliances - - - - - - -	0	10

MOVING VESSELS.

	s.	d.
12. For moving, under the Board's regulations, vessels in the west float requiring the use of the coal hoists or ballast crane, for each 100 tons register measurement, or for any fractional part over 50 tons - - - -	4	0

Vesels can be loaded with coal at the rate of from 300 to 600 tons a day, if a sufficient supply be brought down.

Ballast can be discharged at the rate of 200 tons and upwards a day.

Two of the hoists are provided with lowering tubs, worked by machinery, with the view to prevent the breakage of coal, and the use of these tubs, with the machinery, is allowed free of charge for landing from vessels any pyrites stones, &c. that may be found amongst the coal placed on board by the appliances.

An apparatus for screening coal is also provided.

At each of the hoists, and at the hand tips, Vittoria Creek, there is a machine for weighing coal, if required.

The contractor for shipping coal and discharging ballast, &c. is a licensed master stevedore and master lumper.

The rates are to be paid in advance to the board's treasurer, dock office, Liverpool. Every information can be obtained there, at the office of the traffic manager, district E, Duke Street entrance, and at the coal tips, Birkenhead.

The board recommend parties interested in the shipment of coal to inspect personally the working of the appliances, so that they may estimate the advantages to be gained by their use.

EDWARD GITTINS,
Secretary.

G.

REGULATIONS for working the HIGH LEVEL COAL TRADE at the BRAMLEY-MOORE and WELLINGTON DOCKS.

1. As many vessels and flats to be admitted into the Bramley-Moore, Wellington, and Wellington half-tide docks to work at the high level railway, as shall be consistent with the general work of those docks.

2. No vessel to be allowed to enter the Bramley-Moore, Wellington, or Wellington half-tide docks, nor to be entered on the Application Book for admittance into those docks, to load coal from the high level railway, except upon the production of a jerque note, or a certificate from the master of the dock in which the vessel is lying at the time, showing that she is discharged, and also a certificate from the coal agent that she is to load coal at the high level railway. No coal agent to be allowed to load more than two flats at the cranes at the same time, nor to have more than three vessels in the Bramley-Moore, Wellington, or Wellington half-tide docks (inclusive) loading and to load coal at the cranes, at one time.

No flat to be admitted until a certificate is produced from the coal agent that she is to load coal at the high level railway.

3. Applicants for vessels to be admitted into dock to call at the dock master's office 2 hours after high water, when high water happens between 8 a.m. and 2 p.m.; and when before or after these hours, to call at 10 a.m., when the list of vessels waiting to enter dock will be called over, and orders given for such as are on turn, and represented, to the enter dock.

4. No vessel to be entered in the Berthing Book, kept at the office of the Superintendent of the high level railway, before she is in the Bramley-Moore, Wellington, or Wellington half-tide docks, and each vessel is to be berthed in regular turn, as entered, if the specified quantity of coal is at the Sandhills Station; if not, the next vessel on turn, having sufficient coal ready, to take the berth; any vessel losing her turn in consequence of coal for her not being at the Sandhills Station, to be considered first on turn when the coal is ready. Flats and vessels to follow the same order as to turn for loading, whether entered for the cranes or the shoot.

5. When a crane is idle from want of coal, the first vessel on turn not in the dock having the quantity of coal specified by these regulations at Sandhills Station ready for shipment, (to be proved by a certificate from the coal agent which must also be endorsed by the Superintendent of the high level railway,) may, at the discretion of the dock master, be admitted into dock out of regular turn, as shown in the Application Book. The Superintendent of the high level railway is not to put coal that he has certified for one vessel into any other vessel.

6. No coal to be brought on the high level railway without the permission of the Superintendent, who will inform the railway clerk which vessel is first on turn for a berth, so that the coal may be sent to the high level railway previous to the vessel being berthed.

7. No vessel or flat to be berthed under a crane or a

shoot before the quantity of coal, according to the following scale, is at Sandhills Station, ready for shipment, viz.:—

Vessels or flats under 100 tons register	Full cargo.
Do. do. of 100 ,, ,, and under 300 tons register -	100 tons of coal.
Vessels of 300 tons register and upwards - - - -	150 ,, ,,

The Superintendent of the high level railway to be furnished with a return from the Sandhills Station, at 8 a.m., 1 p.m., and 4 p.m. each day, of the number of loaded wagons (distinguishing box from square wagons) at the station ready for shipment, with the names of the shippers of the coal.

8. Each coal wagon to have a card attached to it, stating the number and weight of the wagon, and weight of the coal thereon; the card to be taken off by the Superintendent, and filed, for a check on the weight shipped.

The gross weight of each waggon of coal intended to be lifted by a cradle crane must not exceed twelve tons; if it exceed that weight, such loaded wagon, will be liable to be returned to Sandhills Station. Wagons sent on to the high level railway without having the requisite cards attached thereto, will also be liable to be returned to that station.

9. Should any delay arise in working any crane or the shoot, from the want of coal for a vessel loading there, or by default of such vessel, that vessel to be immediately removed from the berth, and the next on turn for which coal is ready to be placed therein.

10. Each vessel entered for a berth, to undertake to provide a sufficient number of trimmers; or failing to have a sufficient number of trimmers, and thereby causing obstruction to the full working of the appliances, is liable to be removed from the berth.

11. No transhipment of coal, coke, or other articles from one wagon to another, to be allowed on the high level railway.

12. Vessels, when taking in coal or coke from the high level railway, to be allowed also to take in machinery or cargo from the low quay, when it can be done without causing any delay to the work of the high level railway.

13. Every vessel to leave the dock within 24 hours after she has received the quantity of coal intended to be shipped on board her, if called upon by the harbour master to do so.

14. In the event of a vessel having to vacate her berth, and requiring not over 120 tons coal to complete her loading which is to be proved to the satisfaction of the dock master, one or two flats may be allowed to bring coal into dock for such vessel to the extent of, but not exceeding, 120 tons.

By Order of the Board,
Dock Office Liverpool, EDWARD GITTINS,
March 25th, 1875. Secretary.

DUTIES of the SUPERINTENDENT of the HIGH LEVEL RAILWAY.

1. The Supintendent of the high level railway to keep an account of the vessels that use the coal cranes and shoot; and when a vessel has finished loading or discharging, the amount of tons of coal, or other articles, to be inserted in the Superintendent's Registry Book, and compared with the railway clerk's account; the entry in the Registry Book to be signed by the latter.

2. To enter vessels in the Application Book, and to berth them in regular turn as entered, as per No. 4 regulation; and to prevent vessels grounding under or near the appliances, so that they may be removed any time when required.

3. A dock gateman to be stationed at the east end of the Bramley-Moore and Wellington docks, to attend to the Superintendent's orders, so far as regards the removal and berthing of vessels in connexion with the high level railway.

4. The Superintendent to see that the regulations for working the high level railway are strictly carried out, and, in case of any obstruction or unnecessary delay, to send for the dock master, or the north assistant harbour master, and note the cause in his Memorandum Book.

By Order of the Board,
Dock Office, Liverpool, EDWARD GITTINS,
March 25th, 1875. Secretary.

H.

STATEMENT of CHARGES for the use of the BOARD'S HIGH LEVEL RAILWAY.

COAL EXPORTED.

1. FOREIGN:—

	Per ton.	
For use of High Level Railway -	2*d*.	Collected by the Lancashire and Yorkshire Railway Company, and paid to the Board.
Dock dues - - -	1½*d*.	Collected by the Board.
Town dues - - -	2*d*.	Ditto.

2. COASTWISE:—

For use of High Level Railway -	2*d*.	Collected by the Lancashire and Yorkshire Railway Company, and paid to the Board.
Dock dues - - -	Nil.	
Town dues - - -	2*d*.	Collected by the Board.

3. HOME CONSUMPTION, EXCEPT FOR SALT WORKS:—

For use of High Level Railway -	2*d*.	Collected by the Lancashire and Yorkshire Railway Company, and paid to the Board.
Ditto - - -	3*d*.	Collected by the Board.
	5*d*. per ton.	

4. FOR SALT WORKS:—

For use of High Level Railway -	2*d*.	Collected by the Lancashire and Yorkshire Railway Company, and paid to the Board.
Ditto - - -	2*d*.	Collected by the Board.
	4*d*. per ton.	

5. FOR USE OF SEA-GOING STEAMERS, OR FOR SHIP'S STORES:—

For use of High Level Railway -	2*d*.	Collected by the Lancashire and Yorkshire Railway Company and paid to the Board.
Dock dues - - - Town dues - - -	Nil.	

(*g*.) Letters and Statistics from Mr. R. Cooper Rundell, Assistant to the Secretary, Liverpool Underwriters' Association.

Sir, Liverpool, 30th October 1875.

When I had the honour of placing before the Royal Commission, last June, my evidence respecting spontaneous combustion of coal cargoes, I gave some statistics as to the number of vessels with cargoes of 500 tons of coal and upwards which had sailed from the Mersey on voyages beyond the Equator during the first nine months of 1873 and of 1874, and compared the total number of these cargoes with the number of cargoes in which spontaneous combustion had been reported.

I was then asked if I could inform the Commission how many of the vessels which sailed were iron, how many were loaded on the Liverpool side of the Mersey, and how many by the tip, in order that a further comparison might be made with regard to these particulars.

The tables which I have now the pleasure of sending you herewith supply this information for each month of the two periods. The voyages are classified as before.

Table I. gives the number of vessels which sailed from the Liverpool side of the Mersey, and the number which sailed from the Birkenhead side.

Table II. The number of those vessels which were iron, and the number which were wood.

Table III. The number loaded by tip, and the number loaded by hand.

Table IV. The number of tons of shipping and the number of tons of coal for each month.

Table V. The average tons of shipping and of coal for each month.

In each of the tables the number of cases of heating and fire are printed within parentheses.

My evidence before the Commission showed that the greatest increase in the number of cases of spontaneous combustion in 1874 occurred in shipments of coal from the Mersey for the West Coast of America, and in sending you these tables I take the opportunity to point out some facts supplied by these tables with regard to the shipments in question.

Table I. shows that 41 vessels sailed from the Liverpool side during the first period, and 82 during the second period, while from the Birkenhead side 34 sailed during the first period, and only 17 during the second. There were no casualities to any of the 1873 shipments, while for the second period there were 12 out of the 82 shipments from the Liverpool side, or about 15 per cent., and one only out of the 17 from the Birkenhead side, or 6 per cent.

It would appear therefore from this table that the Liverpool shipments had increased 100 per cent., while the Birkenhead ones had decreased in the same ratio, and that the per-centage of casualties in shipments from the Liverpool side was more than double that from the Birkenhead side.

Table II. shows that 40 iron vessels sailed from the Mersey during the first period, and 40 during the second. Also that 35 wooden vessels sailed during the first period and 59 during the second, representing an increase of 69 per cent. Three casualties occurred in the 40 iron vessels, *i.e.*, in 7½ per cent. of their number, and 10 in the 59 wooden vessels, or in 17 per cent. of their number.

This second table consequently shows that the increased number of vessels which sailed in the second period were of wood, and that the per-centage of casualties from heating was more than twice as great for wooden vessels as for iron.

Table III. shows that, during the first period, 19 vessels were loaded at the tip on the Liverpool side, and during the second period, 43. Also, that 22 were loaded at the tip from the Birkenhead side during the first period, and 10 during the second period. Casualties happened in 12 out of the 43 vessels loaded from the tip on the Liverpool side, or 28 per cent. of the number, and no casualty is reported in the 10 vessels loaded from the tip on the Birkenhead side. No cases of heating are reported in any of the 39 vessels loaded by hand on the Liverpool side during the second period, and although one case occurred in the 7 vessels loaded on the Birkenhead side, there are circumstances connected with it which indicate that the casualty had no connexion with the way in which the vessel was loaded. I allude to the case of the "Merchant.'

Table III. therefore shows that the number of shipments from the tip on the Liverpool side increased more than 100 per cent.; while on the Birkenhead side they decreased in about the same ratio, and that the per-centage of casualties in vessels loaded from the tip on the Liverpool side was 28 per cent., while in those loaded from the tip on the Birkenhead side there were none.

Table IV. shows that while there was but a slight difference in the average size of the vessels which sailed during the second, or of their cargoes, as compared with the average size of the vessels and their cargoes for the first period, yet the tonnage during the hot months of the year shows a great increase in 1874.

Table V. gives the average size of ship and cargo for each month of the periods in question. The average cargoes during the hot months of the second period are larger than the average cargoes during the same months of the first period; but it will be seen that they are not in any case so large as those of some of the early months of the first period.

In many cases, the vessels which sail for the West Coast take only a part cargo of coal, and consequently the average given above does not definitely indicate whether more large cargoes were shipped in the second period than in the first.

Now 10 out of the 13 casualties which occurred in cargoes from the Mersey for the West Coast were in cargoes of 1,300 tons and upwards; and, taking this limit, the following table gives the number of vessels, with 1,300 tons of coal and upwards, which sailed from the Mersey for the West Coast during each month of the two periods selected for comparison.

	1873.	1874.
January	4 sailed.	1 sailed.
February	1 "	None "
March	None "	None "
April	6 "	2 "
May	1 "	1 "
June	2 "	2 "
July	None "	5 "
August	1 "	8 "
September	1 "	5 "
	16 "	24 "

It will hence be seen that 16 such cargoes were shipped during the first period and 24 during the second, representing an increase of 50 per-cent. Also that 20 out of the 24 sailed during the hot months of 1874, while during the same months of 1873 only 4 sailed.

To sum up, therefore, the tables show that in the second period the greatest per-centage of casualties to cargoes from the Mersey to the West Coast occurred, (1), in vessels loaded on the Liverpool side; (2), in wooden vessels; (3), in vessels loaded at the tip; (4), in vessels with cargoes of 1,300 tons of coal and upwards.

Features (1) and (3) relate to *condition* of the coal; while (2) and (4) relate to the vessel and the size of cargo. With regard to these latter elements, it may be observed that several of the vessels, in the cargoes of which cases of spontaneous combustion were reported in 1874, sailed in previous years with cargoes of coal equally large, and no signs of spontaneous combustion were reported. I append the names of some of these vessels, and the kind of coal which they took.

I am, &c.,
R. Cooper Rundell.

The Secretary,
Royal Commission on Spontaneous
Combustion of Coals, London.

TABLE I.—Liverpool and Birkenhead Sailings.

Table showing the Number of Vessels with Cargoes of 500 tons of Coal and upwards which have sailed from the Mersey during each of the first nine Months of 1873 and 1874 on voyages to the South Atlantic, to the Eastward of the Cape of Good Hope, and to the West Coast of America; distinguishing between those loaded at Liverpool and those at Birkenhead.

Note.—The number of cases of heating are printed between parentheses.

PARTICULARS of COAL CARGOES taken on previous Voyages by some of the Vessels which were reported in 1874 with their Cargoes of Coal heated or on fire :—

"Centaur," left Liverpool, August 1871, for Rio Janeiro, with 1,771 tons of Westminster Brymbo main coal, loaded at Birkenhead.

"Glory of the Seas," left the Mersey in July 1872, for San Francisco, with 1,502 tons of Westminster Brymbo steam coal, loaded at Birkenhead.

"Mogul," left Cardiff for Rio Janeiro in November 1872, with about 1,750 tons of South Wales Coal, shipped by Messrs. Goodwin, Barnes, & Co.

"St. Nicholas," left the Mersey in June 1873, with 2,262 tons of South Wales coal, shipped under the tip at Birkenhead, for Callao.

"Euxine," left the Mersey 21st April 1873, for Aden, with 1,950 tons of North Wales coal, shipped at Birkenhead by hand.

"Monmouthshire," left Newcastle, 8th June 1871, for San Francisco, with a cargo of East Coast coal;—left Ardrossan, 13th August 1872, for San Frncisco, with a cargo of Scotch coal;—left Birkenhead, 14th August 1873, for San Francisco, with 1,382 tons of North Wales coal, loaded from the tip.

"Staffordshire," left Dundee, 3rd June 1871, for Calcutta, with a cargo of Scotch coal, and subsequently left Sydney, New South Wales, for San Francisco, with a cargo of Australian coal.

Litherland Park, near Liverpool,
3rd April 1876.

SIR,

IN continuation of the statistics before sent to the Royal Commission, I now beg to forward to you the accompanying tables.

My former statistics related to the number of vessels with cargoes of 500 tons of coal and upwards which had sailed from the United Kingdom on voyages beyond the Equator during the first nine months of the years 1873 and 1874, and to the number of these cargoes in which spontaneous combustion had been reported. I have now extended my data so as to comprise the whole twelve months of each of these years, and have further added similar statistics for the year 1875.

These additions do not materially affect the conclusions previously arrived at.

Tables I., II., III. show the number of vessels (under the same limiting conditions as before) which have sailed from each port for each month of the three years 1873, 1874, and 1875, and the number of cases of heating and fire which have occurred out of these sailings.

Table IV. shows the number of vessels which have sailed from each port for (1) the South Atlantic, (2) the East Indies, and (3) the West Coast, during each of the three years in question.

Tables V., VI., and VII. relate to further particulars respecting the Mersey shipments merely. The number of vessels which have sailed from the Mersey are here given, and the number which have sailed from the Liverpool side distinguished from the number which have sailed from the Birkenhead side, and whether loaded by hand or by tip. The cases of heating are printed between parentheses.

A comparison of Tables I., II., and III. shows that for 1873 there were 26 casualties out of 1,506 sailings, or about 1·7 per cent.; for 1874 there were 54 casualties out of 1,773 sailings, or just over 3 per cent., and for 1875 there were 22 casualties out of 1,619 sailings, or about 1·36 per cent.

Hence it would appear that the great increase of the per-centage of accidents in 1874 has not been maintained in 1875; but that, on the contrary, the per-centage for 1875 is lower even than that for 1873.

An examination of the statistics for the several districts indicates which district shows the greatest relative improvement in 1875 over 1874.

The per-centage for the East Coast has diminished from about 4 to about 1½. That for South Wales from about 1·3 to 0·96. That for Liverpool, from nearly 10 to 3·6; for Birkenhead, from nearly 2 to 1; for Scotland, from 6·6 to 1·3.

The greatest improvement has, therefore, been in Scotch coal. Lancashire coal comes next, and then the East Coast coal. The improvement in the East Coast coal is the more marked from the fact that the per-centage of loss was as high in 1873 as in 1874; while the other districts, particularly the Mersey and Scotch districts, showed such a great increase in 1874 over 1873. Further, if the Yorkshire and London statistics be taken from the returns for the East Coast with which they are included, the decrease in the per-centage of heatings in cargoes from the East Coast (Northern ports) becomes still greater.

Reference to Table IV. will show on what class of voyage the number of casualties have been greatest, and from which districts.

It will be seen that the West Coast voyages are still those which give the preponderance of casualties. The per-centage for West Coast voyages in 1875 is over 3; while, for the East Indian voyages it is under 1, and for South Atlantic voyages it is so low as 0·2.

The East Coast coal contributes the largest per-centage of West Coast casualties. The per-centage is even greater than that for 1874, and this is entirely owing to the Yorkshire shipments.

The remaining tables, V., VI., and VII., refer merely to the Mersey coal shipments, and show that in 1873, 86 vessels loaded at the tip, out of the 264 which sailed, or under 33 per cent.; that in 1874, 144 out of the 357 which sailed, or over 40 per cent.; and that in 1875, 118 out of the 335 which sailed, or about 35 per cent.

I believe these Liverpool statistics respecting the way in which the cargoes were loaded to be fairly accurate; but as they have been compiled within the last few days from the newspaper dock lists and other non-official sources, they may possibly be subject to a few slight errors.*

In addition, I also beg to send you a classified list of those vessels which have sailed from the United Kingdom during 1875, in the cargoes of which spontaneous combustion has been reported. The list gives particulars of ship and cargo.

I am, &c.

The Secretary, R. COOPER RUNDELL.
Royal Commission on Spontaneous
Combustion of Coals, London.

---

* The sailings for the chief of the other coal ports have been obtained from Brown's Monthly Export Lists. In these lists, when more than one vessel have sailed during the month from either port for the same voyage, only the aggregate of their cargoes is given, and not the number of tons of cargo belonging to each vessel. In the tables each vessel is included if the aggregate tonnage of the cargo gives an average of more than 500 tons, and unless the average amounts to 500 tons the vessels are excluded. The tables are thus subject to any slight errors which this may occasion.

TABLE I.—TABLE showing the Number of Vessels which have sailed (S.) from the under-mentioned Ports with 500 Tons of Coal and upwards on Voyages across the Equator, and through the Suez Canal, during each Month of the Year 1873, and the Number of Cases of Heating and Fire (H.) which have occurred out of these Sailings.

(*h*.) PAPER by Mr. A. P. Sandeman, Surveyor under the Marine Department of the Board of Trade.

COAL CARGOES.

THE liability to spontaneous combustion on board coal-laden ships, and the fearful consequences which have lately been reported, appear, and reasonably so, to threaten a serious restriction to our foreign export coal trade, if not to entirely suspend it. We may with truth say a week now seldom passes without its sad tale of loss in many instances of life, as well as of valuable ships, and all attributable to this cause.

The question has been asked in the House whether these startling facts have been noticed, and in reply (through the President of the Board of Trade) the public are informed that a Royal Commission will possibly be appointed to inquire into the subject of "coal cargoes." But "in the meantime" the evil will continue, and this, when a remedy may at once be applied, appears to be a hard case. Ships coal-laden continue to leave our ports daily, whose cargoes are loaded in the same manner, no change whatever occurring to remedy the evil, or indeed any action shown "whatever," as to uneasiness or a sense of any increasing cause for alarm beyond that taken by *underwriters*, who have raised their rates of premium—a clear demonstration of the increased risk.

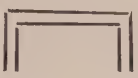
It may, and doubtless is, presumed by many that nothing can be done beyond what is being done to remedy or guard against serious evil, or it may be that they believe extra special care is being taken, or possibly they altogether ignore the practicability of doing anything that would further protect their vessels from the risk of being burnt and the lives of the crew from the perils which must necessarily attend such a calamity, and hence the evil continues and is likely to do so. I believe all shipowners are interested in this matter, but all are not agreed as to the causes which contribute to spontaneous combustion of coal cargoes. One class of shipowner will show constant interest by adopting all "ordinary precautions," a platform is laid, and vertical shafts are introduced at each hatch, and where no permanent 'tween deck is laid, fore and aft trunks are laid on or under the lower beams, with thwartship connexions to the vertical hatchway shafts. "This is all in the right direction," but it is inefficient, and requires to be extended more thoroughly through the cargo to be effective. In other instances the kelson *only* is ventilated; this is a matter of economy and is seldom of much use, as it is not frequently well or effectively done. The vertical hatch shafts are led into this, and if the line of kelson remains clear the circulation or current of air is to a limited extent maintained. In other cases again, and not a few, little or no interest is manifested "*whatever*" in ventilating, and no effort is made to prevent the coals heating or to carry off any combustible gas that may generate.

However carefully the ventilation may be arranged, even presuming it was sufficient to keep the cargo cool, so little interest is taken in the matter that it frequently gets damaged and is rendered useless before the loading is completed. I could instance cases where large vessels taking nearly 2,000 tons have been ventilated with all "ordinary" care, but that done no further interest was apparently manifested, the master may not have joined, the overlooker is merely on board occasionally, and the mate, as a rule, seldom knows anything about it. The coal trimmers are left in possession of the hold to load the vessel as they please, and they care little about the ventilators. One vessel in particular as a "case in point" came under my observation. She belonged to a Liverpool firm who are reputed for their care in ventilating; her kelson was ventilated, she had well-made ventilators in each hatch, and longitudinal shafts intermediate and in the wings which had connexion with the hatchway shafts, and appeared to be in order; as an underwriter's surveyor I had in ordinary course to report on the vessel, and I found the whole of the three hatch ventillators had got damaged and were filled with coal within a few feet of the top, and the coal had broken down the kelson ventilation both at the fore and after ends. I met one of the owners and the overlooker on board who were ignorant of the damage, and the mate could give no explanation.

It is very different with rice cargoes, for the preservation of which a most careful system of ventilation is adopted, which under ordinary circumstances in proportion to the cargo is about five times greater than what it is in coal-laden vessels. In the carriage of grain a loss may be attributed to the owner, or if the cargo sweats the reputation of the ship will suffer, and hence every care is taken to keep a cargo very liable to heat from doing so, master and officers are prompted and encouraged to superintend the laying of the ventilation, and every care is adopted to protect the owner from loss. But with coal cargoes, where life is frequently jeopardised, it appears to be almost completely the reverse; in most cases the coal is put on board heavily charged with moisture and liable to heat if confined under hatches. Ventilation may or may not be arranged, but as a rule no one seems to be employed to look after it, and to see that it is not damaged; the cargo is not unfrequently hurried in from the Birkenhead tips or high-level quays, and all is left to stevedores, and, the cargo in, the hatches are put on, and in many cases if combustion is the result it is little to be wondered at.

If coal-laden ships were placed on a par with rice-laden ships in the matter of ventilation, and the same observant care taken whilst loading, I am persuaded we should hear no more of these calamitous events. The system of ventilation would merely have to be more in detail, and if it is admitted that *perfect ventilation* will keep coal from heating, as it does a rice cargo, then detail becomes a matter of easy arrangement.

The platform, as in rice-laden ships, is most essential, as it affords a free circulation of air underneath. I would step large vertical shafts on the middle line in each of the hatchways to rise above the coamings, to be protected and secured so as to be open in all weathers. Other vertical shafts should be placed in proportion to the size of the vessel intermediate from the middle line in towards the wings spaced about 25 feet apart, all the vertical shafts to pass through the platform.



Section showing the vertical shafts and the intermediate fore and aft shafts leading into them; the fore and aft shafts are open underneath.

Fore and aft shafts should be placed in connexion with the intermediate and middle shafts on the lower deck beams and about half-way from lower deck to platform, and also fore and aft shafts in the wings on both sides; the whole of these longitudinal shafts to penetrate the cargo from end to end.

Transverse shafts should also be fitted to connect the fore and after with each other and with the vertical hatch shafts "always open," thus there would always be a current of fresh air passing through the cargo. Deck ventilators might also be fitted forward and aft to supply fresh and carry off heated air.

So ventilated there would be a column equal to a square foot of fresh air passing through every square block of 40 tons, and so ventilated it would be most improbable that coal, however wet or liable to sweat when confined, could do so so as to endanger spontaneous combustion. The cost would of course be much greater than it is at present constructed, but I apprehend it would not greatly exceed 1*s*. 6*d* per ton on her cargo, and when value is allowed for the material when sold at the port of destination it would be considerably less.

This system of ventilation has been advocated by the underwriters for years past, and their surveyors have been *specially instructed* to recommend its adoption; and the sooner it is insisted upon and made compulsory the sooner will we cease to hear of the sad and revolting catastrophes which have lately resulted from spontaneous combustion with coal cargoes on foreign voyages.

In meantime I would submit that until some remedy is adopted so that coal cargoes can be carried to distant ports without danger of fire, vessels so laden should be required to carry properly fitted "life-boats," found with mast and sail, and having provision tanks, water breakers, and boat compasses ready for use in case of need; and considering the painful evidence which we have had of the danger to which such cargoes expose the vessel, and consequently the crew, they appear to be special cases almost calling for supervision under section 12 of the Merchant Shipping Amendment Act of 1873, as defective in equipment (boats) for their intended voyage.

(Signed) A. P. SANDEMAN.

Liverpool, 3rd March 1875.

(*i.*) PAPER by Mr. Jeula. (See his Evidence, page 141, Q. 12.)

LOSSES OF COAL-LADEN VESSELS.

THE only way of really ascertaining the facts as to losses of ships and lives which have already occurred is to tabulate the number and dates of clearances for, say, five years, stating the vessel, her flag, size, crew all told, the description and quantity of coal shipped in her, and her voyage, with any other available particulars; if this were done, reliable information would soon be obtained, but a comparison between the number of voyages entered upon and the number of casualties occurring is absolutely necessary to a correct estimate of results.

I venture respectfully to suggest that the following heads of inquiry would be of importance for future guidance:—

A. The special character of different coal ordinarily shipped, on long or short voyages, as to elements of combustion, hardness or softness, and probable crumbling and breaking up, or the contrary?

B. The results of shipping it wet or dry, large or small, and by barrows or from a tip?

C. The influence of recent strikes upon the out-put, and the results of more immediate transfer of coal from the mine to the ship consequent thereon?

D. Whether, when laden in large or small vessels, it is more or less dangerous, and whether explosions are more frequent in small vessels and spontaneous combustion in large vessels?

E. Whether usually ventilated or not; whether different customs as to ventilation prevail at different coal ports, consequent upon special kinds of coal being shipped therefrom, or otherwise; and, if ventilated, whether at the top over the coal only, or by vertical, with or without horizontal, ventilators, near the keelson, or higher up in the body of the cargo, or by any or all of these means, or by any others, and if so, whether by wooden, metal, or earthenware ventilators; and the results of the various systems?

F. What means are generally employed for putting out a fire in a coal-laden vessel when it occurs? Could steam be used with advantage (especially in steam vessels) in preference to water, and if so, could arrangements be made without very much difficulty or expense for applying it in case of need?

G. The relation of the vessel's registered tonnage and her crew to the quantity of coal shipped in her; and whether this relation varies in consequence of the different character of the coal, or with the different ports from or to which she sails, or with different seasons of the year?

H. Whether unguarded lights, or safety lamps, are generally used on board coal-laden vessels, and if any special rules are adopted?

HENRY JEULA,
20th April 1875. Lloyd's, E.C.

MINUTES OF EVIDENCE

TAKEN BEFORE THE

ROYAL COMMISSIONERS

APPOINTED TO INQUIRE INTO THE

SPONTANEOUS COMBUSTION OF COAL IN SHIPS.

Tuesday, 20th April 1875.

PRESENT:

THE RIGHT HONOURABLE HUGH C. E. CHILDERS, M.P., IN THE CHAIR.

Sir GEORGE ELLIOT, Bart., M.P.
HENRY HUSSEY VIVIAN, Esq., M.P.
FREDERICK AUGUSTUS ABEL, Esq., F.R.S.
RICHARD CORY, Esq.
GEORGE DUNCAN, Esq.
JOHN FENWICK, Esq.
JOHN FERGUSON, Esq.
CHARLES ICELY, Esq.
JOHN PERCY, Esq., M.D., F.R.S.
WILLIAM YOUNG, Esq.
J. M. CARMICHAEL, Esq., Secretary.

Captain HENRY M. HOZIER, Secretary of Lloyd's; HENRY JEULA Esq., Underwriting Member of Lloyd's, examined.

Captain H. M. Hozie and H. Julia Esq.

20 April 1875.

1. (*Chairman to Capt. Hozier.*) You are secretary to Lloyd's?—I am.

2. (*To Mr. Jeula.*) What position do you hold at Lloyd's?—I am an underwriting member of Lloyd's, and was honorary secretary to the Statistical Committee of Lloyd's at its commencement.

3. You have taken a great interest in the statistics of this question before us?—Yes, in this question with others.

4. (*To Capt. Hozier.*) Have you any information to lay before the Commission in connection with the subject of their inquiry?—I put in a list of coal-laden vessels posted at Lloyd's as lost or damaged through fire in 1874,* showing the results to the vessel and cargo. I also put in a list of missing coal-laden vessels (*handing in the same.*)†

5. Can you give us at present any further information about any of those ships?—I would rather do that later. I may mention that in the year 1872 only 14 coal-laden vessels were posted as missing, all being sailing vessels. In 1873 45 were posted as missing, 41 being sailing vessels, and four steam. In 1874 the number was 35, 31 being sailing vessels, and four being steam vessels. In the first quarter of 1875 the number was 10, seven being sailing, and three being steam vessels.

6. Could you give a similar list for any number of years previous to 1872?—We could furnish such a list for any number of years back.

7. The materials are available for carrying it back 10 years?—Yes.

8. The commissioners would be glad to be furnished with a similar list for 10 years back if you could give it them?—I will have such a list prepared.

9. (*Mr. Vivian.*) Could you give the proportion which those ships bear to the total number of ships laden with coal?—I will furnish that.

10. Could you also compare the number of coal-laden ships lost or damaged or missing in the years for which you give the return with the total number of ships that have sailed laden with other goods which have been also reported lost or damaged or missing, because many may have been lost, not by the spontaneous combustion of coals but by ordinary casualties of the sea?—I will furnish such a comparison.

11. One question which would arise would be whether the ships which load with coal are in the main of a lower class than other vessels; whether some portion of the excess of missing coal laden ships, if there is any such excess, is due to the class of ships; will you therefore give the classes of the vessels, and specify whether they were iron or wooden vessels?—I will give those particulars.

12. (*Chairman to Mr. Jeula.*) Have you any suggestions to make to the Commission?—I hand in a paper containing a few suggestions as to some directions in which I think inquiry would be useful (*handing it in*).‡

13. (*To Capt. Hozier.*) Have you anything else to put before the Commission at present?—I hand in a letter from the Coal Inspector of the Peninsular and Oriental Company to the Committee of Lloyd's (*handing in the same*).§

The witnesses withdrew.

NOTE.—The form and scope of the returns alluded to in questions 6 to 11 were subsequently modified, in consideration of the serious expense which their preparation would have incurred, but the returns which were prepared by Lloyds for the Commission will be found at pages 101 and 108.

---

* *See* Appendix, page 104.

† *See* Appendix, page 108.

‡ *See* Appendix, page 140.

§ *See* Captain Steinson's letter quoted by Mr. Price, page 177.

T. H. Farrer, Esq.

20 April 1875.

THOMAS HENRY FARRER, Esq., examined.

14. (*Chairman.*) You are permanent secretary to the Board of Trade?—I am.

15. This Commission, I think, originates from the Board of Trade, though it is in form issued by the Home Office?—That is so.

16. Will you state to the Commission the circumstances under which you recommended its issue?—There had been a considerable number of cases in which coal-laden ships were lost by fire, in which the Board of Trade had ordered inquiries under the provisions of the Merchant Shipping Acts, and they took some pains in some of the later inquiries to get scientific evidence, and to go as fully into the question as they could. They found, however, that the tribunal before whom those inquiries were conducted, that is to say a magistrate and two nautical assessors, was scarcely competent to investigate the scientific and complicated questions that arose, and they therefore thought it was useless to order more inquiries which did not produce any great elucidation of the subject. Lloyd's Committee thereupon, I will not say remonstrated, but desired that there should be further inquiry, and we had some correspondence with them upon the subject, and also with the Salvage Association of which Mr. Harper is secretary. The result of that correspondence was that the Board of Trade ascertained that those bodies desired not so much further statutory inquiries under the Merchant Shipping Act, as a careful investigation such as could only be conducted by a body specially appointed for the purpose, and in the end this Commission was appointed.

17. Can you put that correspondence before the Commission?—I will put in the whole of the correspondence.*

18. Can you also furnish us with the minutes of the evidence taken in inquiries in special cases?—I put in the minutes of the whole proceedings containing the evidence on the two inquiries which throw most light upon the subject, viz., the inquiries into the cases of the Herbert Graham and the Minnie Graham, and I put in a list of the cases in which we have had inquiries. I also hand in copies of the abstract of the Wreck Register in which the results of those inquiries are stated generally (*handing them in*). If the Commissioners think it it desirable to have before them the evidence taken on the inquiries in the other cases, I can produce it.

19. (*Dr. Percy.*) I think it would be desirable to have the proceeding on the other cases?—I will send the minutes of the proceedings in the whole of those cases.†

20. (*Chairman.*) Besides holding those inquiries have you had any correspondence with the officers at the ports on the subject?—No, I think we have had no correspondence that throws any light upon this question.

21. So that the inquiries, and the correspondence with Lloyd's, and with the Salvage Association, tell the whole tale as far as the Board of Trade can give it?—They do.

22. You have held 12 inquiries into the causes of the burning of coal-laden vessels since 1868?—Yes.

23. Is there any special reason for selecting the two cases of the "Herbert Graham" and the "Minnie Graham"?—I took out those two because in looking through them it appeared to me that the subject was gone into more fully in those cases than in any others, and some scientific evidence was taken in those cases.

24. Have you anything else to put before the Commission at the present moment?—Only two returns, one of which has been presented to Parliament, and the other is on the point of being presented (*handing them in*).

25. That is the whole of the information which Parliament has about the burning of coal-laden vessels at sea?—Yes. I could of course give from our wreck returns the proportion of losses of coal-laden vessels to the losses of vessels laden with other cargoes. I could get a return of that sort made out; but without a great many more details than we could give, I doubt whether it would be of much value.

26. Lloyd's would probably be able to give such a return as completely as it could be given?—Yes. From some experience in trying to get at results from statistics of that kind I am not very sanguine about getting very important results from them.

27. (*Mr. Vivian.*) The Board of Trade take cognizance only of English ships?—Only of British ships.

28. (*Sir G. Elliot.*) You, generally speaking, have stated that 12 inquiries have taken place into losses by fire of coal-laden vessels; what proportion do you suppose they represent of the total number which have taken fire within the period?—I could tell you what proportion they bore to the total number that we know to have taken fire. I can tell you nothing about missing vessels.

29. Have you any impression what proportion it would be?—Not at this moment.

30. The ships which come under your jurisdiction are called British vessels; what proportion would the casualties we are speaking of in British vessels bear to similar casualties in the whole of the vessels carrying coal sailing from British ports?—I could not tell you that.

The wiitnss withdrew.

Adjourned.

Tuesday, 1st June 1875.

PRESENT:

THE RIGHT HON. HUGH C. E. CHILDERS, M.P., IN THE CHAIR.

SIR GEORGE ELLIOT, Bart, M.P.
HENRY HUSSEY VIVIAN, Esq., M.P.
FREDK. AUGUSTUS ABEL, Esq., F.R.S.
RICHARD CORY, Esq.
GEORGE DUNCAN, Esq.
JOHN FENWICK, Esq.
JOHN FERGUSON, Esq.
CHARLES ICELY, Esq.
JOHN PERCY, Esq., M.D., F.R.S.
WILLIAM YOUNG, Esq.

J. M. CARMICHAEL, Esq., Secretary.

Mr. R. C. Rundell.

1 June 1875.

Mr. R. COOPER RUNDELL examined.

31. (*Chairman.*) Will you tell the Commissioners what position you occupy?—I am assistant to the secretary to the Underwriters' Association of Liverpool.

32. I believe you have given a good deal of attention to the question which is specially referred to this Commission?—I have given it attention for some five or six months past, particularly to a point which is of special interest to underwriters, namely, the increased marine risk; and it was with the view to discover the probable cause of the spontaneous combustion of coal in ships, and to afford some means of estimating the increased risk, that I prepared some statistics which I have recently presented in the form of a report to the Underwriters' Association. The committee have desired me to state that they will be

---

* *See* Appendix I., page 1.

† *See* Appendix II., page 4.

Mr. R. C. Rundell.

1 June 1875.

pleased to present the Commissioners with a copy of the report when it is finally printed; it is already in the hands of the printer.

33. That report will be issued to your own body, and published for private circulation?—Yes.

34. I think you have collected some statistics with reference to three-fourths of the year 1873, and you are able to compare those with the corresponding period of the year 1874?—Yes.*

35. What was your particular object in taking three-fourths of the year, and not the whole year?—At the time when I commenced this investigation sufficient time had not elapsed for the completion of the voyages for the year; it was with the view of having all the voyages completed that I took the nine months instead of the 12 months.

36. However, what you have is a complete analysis of the results in coal-laden ships, sailing with above a certain quantity of coal, and crossing the Equator, during similar periods, in the two years?—Yes. I have taken vessels carrying 500 tons of coal and upwards. The reason for selecting the first nine months of each year was, as already stated, to allow time to ascertain the result of each sailing, and the reason of selecting the two elements of carrying over 500 tons and crossing the Equator was because a preliminary investigation showed that the heating and fires chiefly occur in vessels with cargoes of 500 tons and upwards, and that a considerable time usually elapses before the signs of heating are discovered.

37. Will you give us the results of the statistics you have collected with regard to those vessels from this country which have crossed the Equator carrying 500 tons or more of coal during those two periods, namely, the three first quarters of 1873 and the three first quarters of 1874?—An examination of the facts collected show, first, that in the cases selected for comparison no fires occurred before the 37th day after leaving port, while in one case there was no evidence of fire before the 190th day. The greater number of fires have, however, occurred about the 60th day. Secondly, that the fires have not been confined to one kind of coal, but have occurred in most, if not all, of the varieties which are usually exported. In fact, the inquiries which have been made support the opinion that no kind of ordinary coal containing hydrogen has entire immunity from spontaneous combustion. Thirdly, we find that fires occur in the cargoes whether the coal be ventilated or not, whether loaded in summer or winter, by tip or by basket. Among the instances are vessels ventilated by shafts through the coal, both horizontally and vertically, by vertical shafts only, and by means of platforms and side linings which allow a circulation of air under the cargo from one end of the ship to the other. Some of the cargoes also are especially named as having been shipped in fine weather. It is probable, however, that there is a certain amount of moisture always present in all coal.

38. Those are the general conclusions which you have come to; will you give us the statistics upon which those conclusions are based. In the first place, how many vessels as to which you have information sailed with cargoes of above 500 tons on voyages crossing the Equator during the nine months in each year?—In the first period, that is to say, the first nine months of 1873, 1,133 vessels sailed. Out of those there were 23 casualties from spontaneous combustion, or about two per cent. In the second period, that is to say, in 1874, there were 1,240 sailings, out of which there were 50 casualties, or about four per cent.

39. Those are casualties connected with fire?—Yes.

40. Do those casualties include missing vessels?—No. I have a separate list of missing vessels out of those particular sailings. In the nine months of 1873 out of the 1,133 coal-laden vessels which sailed from the United Kingdom (not necessarily British ships) there were five missing vessels, and in 1874 out of the 1,240 there were seven missing vessels.

41. That is to say, in 1873 there were 23 disasters known to have arisen from fire, and five missing ships?—Yes.

42. And in 1874 there were 50 casualties known to have arisen from fire and seven missing ships?—Yes; several of those were ships that probably foundered at sea. I have examined each case on its merits, and in the case of some of them wreckage was picked up, or there was some sign from which it might be presumed that the vessel had not been burnt.

43. You have limited your inquiries to vessels that crossed the Equator?—Yes.

44. (*Mr. Young.*) You say they are "selected" cases; what do you mean by selected cases?—I have selected those ships carrying 500 tons and upwards, and I have also selected those crossing the Equator.

45. Do the 1,133 and the 1,240 comprise every ship carrying above 500 tons of coal that crossed the equator?—Yes, from the United Kingdom.

46. (*Chairman.*) Then you have classified those sailings according to the districts from which the coal was shipped?—Yes. I have adopted a classification of the coal ports already in use, viz., East coast ports for north country and Yorkshire coal, South Wales ports for South Wales coal, Liverpool and Birkenhead for Lancashire and North Wales coals respectively, and Scotch ports (both east and west) for Scotch coal. The facts brought out in this classification and comparison are shewn in the following figures: Out of 268 sailings from the east coast ports during the first period, there were 13 casualties, or 4·85 per cent., while during the second period, out of 312 sailings, there were 15 casualties or 4·81 per cent. This shows that although in each year there is a high percentage of casualties in coal from the east coast ports the percentage has somewhat decreased in the second period, that is as to the east coast. There is one fact that may be interesting with respect to the east coast shipments. It is by the addition of the Yorkshire and London statistics that the east coast returns show a decrease in the percentage of casualties. If these be taken from the returns of the east coast ports, the number of casualties for the first period will be about four per cent., while for the second period it will be about five per cent., thus showing an increase of 25 per cent.

47. On what?—On the casualties in the cases of vessels from the northern ports; that is to say, by taking away the South Yorkshire and London shipments.

48. (*Sir George Elliot.*) You mean the coals shipped at Grimsby have not given such a result as regards spontaneous combustion as the coals shipped at the northern ports?—The Yorkshire ports have shown a decrease, while the northern ports have shown a slight increase in the percentage of cases of heating.

49. (*Dr. Percy.*) Do the figures you are giving comprise cases of heating only, or do they include cases of explosion also?—They apply to cases of spontaneous combustion alone. I have not taken account of any case where I had reason to suppose that it was a case of explosion.

50. (*Chairman.*) Will you now pass to shipments from another district?—I will pass to the South Wales district. Out of 587 sailings from South Wales ports during the first period, there were seven casualties, or about 1·19 per cent.; while during the second period out of 589 sailings, there were 10 casualties or 1·7 per cent. This shows that in each period there has been but a small percentage of casualties in coal from the South Wales ports, but that the percentage has increased nearly 50 per cent. in the second period. Next taking the Liverpool district. From the Mersey there are two very distinct classes of coal shipped, namely, the North Wales coal and the Lancashire coal. Lancashire coal is shipped on the Liverpool side of the Mersey, and the North Wales coal on the Birkenhead side. Taking the shipments at Birkenhead there were 120 sailings from Birkenhead during the first period, and out of those there were no casualties. During the second period out of 133 sailings, there were three

---

* Mr. Cooper Rundell's Statistics, revised and extended by him for the information of the Commission, will be found in the Appendix, at page 127.

Mr. R. C. Rundell.

1 June 1875.

casualties or 2·27 per cent. From Liverpool there were 69 sailings during the first period, and out of these there were no casualties, while during the second period, out of 109 sailings, there were 13 casualties or 11·9 per cent. Passing to the Scotch ports (east and west), out of 89 sailings from Scotch ports (east and west), during the first period there were three casualties, or 3·37 per cent.; while, during the second period, out of 97 sailings, there were nine casualties or 9·28 per cent. This shows that while the percentage of casualties in the coal from the Scotch ports is high in each period it has increased in the second period nearly threefold.

51. Can you give the Commission not only the class of coal or the seam from which the most dangerous coal seems to come as shown by the aggregate losses but the percentage on the shipments?—No. Underwriters would be very pleased to be able to get that information; it has been only in a few cases that I have been able to obtain it. From Liverpool there were 13 cases of heating, seven of which occurred in coals supplied from one firm and four of which occurred in coals supplied by another firm. A glance at the names of the different kinds of coal which have heated will show that while they are generally subject to this danger of spontaneous combustion, there are two or three which are conspicuous from the frequency with which they recur. It must not, however, be hastily concluded that the latter are of a more dangerous kind as the shipments may also be more numerous. I may mention that, although some Lancashire coal has been burning, there are some very distinct varieties of Lancashire coal. There is the cannel coal, which is considered a very safe coal.

52. (*Mr. Vivian.*) I presume there have been no cases of spontaneous combustion in the case of cannel coal?—I have not heard of any at all, it is looked upon by the Liverpool underwriters as a very safe class of coal. They have also in esteem several other kinds of coal that go from Liverpool which I could mention. The best Orrell coal bears a high character.

53. You cannot classify the Lancashire coals in any way so as to distinguish between those that are combustible spontaneously and those that are not?—No, but certain kinds, such as Crow Orchard coal, are thought to be more liable to spontaneous combustion, and Liverpool underwriters who discriminate between the different kinds of coal do not care to insure them.

54. You cannot distinguish as between dry coal and bituminous coal, that is to say, coking coal and non-coking coal?—No, I do not find that Liverpool underwriters go into that question, though bituminous coals are avoided by some.

55. That is to say, coking coals?—Those that cake. In west coast voyages there is the largest increase in the number of casualties in the second period as compared with those in the first period and this increase proceeds chiefly from coal shipped at Liverpool and from South Wales ports. In the Liverpool sailings to the west coast the greater number of cases of heating were in cargoes of Lancashire coal, while in the South Wales sailings, but with one exception, all were in cargoes of bituminous coal shipped, I believe, for smelting purposes.

56. (*Chairman.*) You have given us an analysis of casualties with reference to the districts from which the coal was shipped, can you tell us out of so many ships carrying north country coal, for instance, what percentage of casualties there would be, and out of so many ships carrying Welsh coal what percentage of casualties there would be?—Yes. Taking the different districts, the east coast ports, for instance, I could tell you, out of the number of casualities, what coal in particular cases was shipped by one shipper and what by another shipper. I could give the names of the vessels.

57. Could you analyse the return and give those statistics?—Yes; I will furnish that to the Commission, but I could not give the percentage of casualities on the shipments of any class of coal. I can only say in how many cases heating occurred with Scotch coal or Lancashire coal, and so on.

58. With reference to the class of shipping in which these casualties occur, I think you have some information to give the Commission?—Yes. In the first period in which the casualties which I have mentioned occurred, the average tonnage of the vessels was less than in the second period. Only one third of the vessels in the first period are over 1,000 tons, while in the second more than half of them are above that tonnage. In the second period there are eight vessels above 1,500 tons, and only two in the first period. To estimate how far the greater size of the ships explains the larger number of cases in the second period it would be necessary to ascertain if the average tonnage of the vessels which sailed during the second period is much greater than in the first period. Those particulars I have not had an opportunity of getting for the whole of the districts, but I have the particulars for Liverpool.

59. Have you distinguished between sailing ships and steamers?—I have taken steamers when they have taken a cargo of coals, but not when they have taken coals for merely bunker use.

60. Have you distinguished in the 1,133 and the 1,240 how many were steamers and how many were sailing ships?—No, but I can do so hereafter, so far as Liverpool is concerned. Nearly the whole of those vessels whose cargoes heated were first-class vessels, vessels holding a high class in the register. I may mention that from Liverpool for the eight months to the 31st of August 1874 I find that the number of sailings of iron vessels to wooden ones bore the proportion of about one to three; of the whole number of sailings about a fourth were iron vessels, but taking voyages to the west coast of America the iron vessels were about 75 per cent. of the whole number of sailings. A much greater proportion of iron vessels seem to have gone to the west coast of America. Among the vessels before referred to whose cargoes heated, the proportion of iron to wood is greater in the second period than it is in the first. Seven out of the 24 iron vessels were built during the second period. In connexion with the character of the ships to which casualty occurred, the depth of hold is a point worth noting as influencing the breakage of the coal. The depth of hold in the second period averages about 16 inches more than in the first period. But the mere depth of hold without taking into account the number of laid decks will only imperfectly indicate the mass of the cargo. The "Glory of the Seas" has by far the greatest depth of hold but she has three laid decks, so that the coal could be turned over when necessary. The captain also reports that his being able to turn over the coal and expose it to the cooling effect of the air, enabled him to bring his ship to San Francisco.

61. With regard to the number of days that elapsed in the cases of the casualties to which you have referred between the period of the sailing of the ship and the first indication of heating, have you any information to give us?—In a table which I have here, the 73 cases to which I have already referred are arranged to show the number of days that elapsed between the sailing of the ship and the first indication of heating. The earliest case occurred when the vessel was between 10 and 20 days out, in the latest the fire occurred nearly 200 days after sailing, and when the vessel had been in port about nine days. Indeed, the number of cases which occur after the arrival of the vessel in port shows that extra care should be taken at this time. It has been suggested that the heating is caused by the access of air when the hatches are taken off, and the discharge commenced, but in the case of the "Merom" the fire was in the fore compartment where the discharge had not begun. In another case, the "Respigadera," I am informed that until her arrival in San Francisco there was no sign of heat in the coal.

62. Can you give us the number of cases in which casualties occurred after leaving port within the first month, and the number in which they occurred in

Mr. R. C. Rundell.

1 June 1875.

the second month, and so on?—Yes. In 1873, I have found no cases until after the fortieth day, between 40 and 50 days out, there was one case; between 50 and 60 days out, two cases; between 60 and 70 days out, three cases; between 70 and 80 days out, three cases; between 80 and 90 days out, three cases; between 90 and 100 days out, one case; between 100 and 110 days out, four cases; between 110 and 120 days out, two cases; between 120 and 130 days out, one case; between 130 and 140, one case; none between 140 and 190 days out; one case between 190 and 200 days, making 22 cases; and then there is the case of the Arracan, where I have not been able to get the time.

63. That exhausts the 23 cases of the first period?—Yes.

64. Can you give the corresponding particulars for 1874?—The first case occurred between 10 and 20 days out; the next case between 30 and 40 days out; the next nine cases between 50 and 60 days; the next six cases between 60 and 70 days; the next two cases between the 70th and 80th day; the next four cases between the 80th and 90th day; the next six between the 90th and 100th days; the next six between the 100th and 110th day; then there were two cases between the 110th and 120th day; one case between the 120th and 130th day; three cases between the 130th and 140th day; one case between the 140th and 150th day; and four cases between the 150th and 160th day, making 46 cases. Then there were five cases in which I have not been able to obtain the exact period. The coal carried in those cases being: Tyne coal by the "Unione," Bower's West Hartley by the "Maassluis," Powell Duffryn steam coal by the "Lady Louisa," and Brancker's Orrell coal by the "Victorine." I may remark that this table affords no indication that spontaneous combustion is more quickly developed in coal from one district than in that from another, and with different kinds of coal, the greatest number of heatings occur about the 60th day after leaving port.

65. Have you any statistics bearing on the question of temperature?—The tables I have here show very decidedly that the summer sailings are the most dangerous, that is to say, those for the months of June, July, and August. In 1873 the largest percentage of cases occurs in the August sailings, in 1874 it occurs in those for July. If the different districts be compared in this way, the following is the result: from the east coast district in 1873 the greatest number of casualties occurred in the sailings in June, and in 1874 in July. From the South Wales district the greatest number of casualties in 1873 occurred in June, and in 1874 in July. In the Liverpool district in 1873, there were no fires, in 1874 the greatest number of casualties occurred in June. In the Scotch district in 1873 the greatest number were in August, and in 1874, July.

66. These are the dates of sailing?—Yes.

67. Have you any percentages as to the dates of the casualties?—The greatest number of casualties have occurred in September and October.

68. Must not your statement be qualified by this, that you do not give any statistics as to the ships which sailed in the last quarter of the year?—Yes.

69. So that the comparison is only between the sailings of the first nine months of the year?—Yes. My statistics refer to these periods, but I have a table which shows graphically the period of the year over which a much greater number of voyages in which casualty has occurred have extended, and that table shows that these voyages have occurred during the hot period of the year. That table includes 128 cases. It embraces a period from 1868 to 1874, and about a half of the whole number of cases occurred in 1874. I will furnish the Commissioners with that table. There are two points worth noting while considering the effect of temperature, that is when and where the first signs of heating were discovered. In selecting those voyages only which extend beyond the Equator there is necessarily a high temperature for a large portion of each voyage. It will be found in each year that the greatest number of heatings occurs in September and October. As regards geographical position in the first period, out of 23 cases 11 occurred in the Atlantic, and 12 to the east of the Cape of Good Hope. In the second period out of 50 cases, 30 occurred in the Atlantic, 14 to the east of the Cape of Good Hope, and six on the West Coast of America. If we compare these with the total number of selected vessels which sailed into the three geographical divisions thus indicated, to the South Atlantic division must be added the sailings east of the Cape of Good Hope and west of Cape Horn (excluding the Indian sailings by way of the canal). These selected sailings into the South Atlantic are about 1,129 for the first and 1,237 for the second period. Comparing with these numbers the respective Atlantic casualties, the percentages are for 1873, 0·97 per cent.; for 1874 2·43 per cent., an increase of more than 150 per cent. If the sailings for the Indian Ocean are compared in the same way the resulting percentages are 2·41 and 2·56 respectively, or an increase of only about six per cent. for the second period. For the West Coast, in the first period, there were no casualties out of 235 sailings, while, in the second period, out of 283 sailings there were six, or 2·11 per cent. This shows the relative increase for each of the three divisions.

70. That is with reference to the voyage?—Not as regards whether it was a West Coast voyage or an East India voyage, but showing the division where the casualties have occurred, and the percentage is on the number of vessels which sailed from the United Kingdom *into* that division.

71. Have you also statistics with reference to the voyage?—Yes; by comparing for each period the selected sailings for the three divisions with the casualties respectively belonging to these sailings, we obtain the following results:—For South Atlantic voyages in the first period there are four heatings in 399 voyages, or about one per cent.; in the second period there are three heatings in 410 voyages, or about three-quarters per cent., or a slight decrease in the danger on these voyages. For Indian voyages in the first period there are 14 heatings in 499 voyages, or 2·81 per cent.; in the second period there are 23 heatings on 546 voyages, or 4·21 per cent., an increase of about 50 per cent. For West Coast voyages in the first period there are five heatings in 235 voyages, or 2·13 per cent.; in the second period there are 24 heatings on 284 voyages or 8·44 per cent., an increase of nearly 300 per cent. This shows a remarkably large increase in the number of cases of spontaneous combustion in coal shipped to the West Coast ports.

72. Have you any explanation to give of that?—I have separated them into districts to show where the coal came from, and the details are as follows: From the east coast ports in the first period there was one casualty out of 21 sailings, or about five per cent.; in the second period there were three out of 62 sailings, or about five per cent., the same as before. From the South Wales ports in the first period there were four casualties out of 122 sailings, or 3·28 per cent.; in the second period there were seven out of 101 sailings, or an increase of more than 100 per cent. From the Mersey in the first period there were no casualties out of about 71 sailings; in the second period there were 13 out of 99 sailings, or over 13 per cent. In the second period there were 12 cases out of about 82 sailings from the Liverpool side of the Mersey, while there was only one out of 17 sailings from the Birkenhead side. From Scotch ports there were no casualties out of 21 sailings in the first period, and in the second period there was one out of 22 sailings.

73. These all refer to voyages to the West Coast?—These all refer to voyages to the West Coast. The great increase, therefore, in the percentage of casualties in West Coast voyages occurs in coal shipped at Liverpool and the South Wales ports. I may repeat what I said before that 12 out of the 13 cases of heating in these sailings from the Mersey were in cargoes of

Mr. R. C. Rundell.

1 June 1875.

Lancashire coal, while those in South Wales cargoes were generally in bituminous coal.

74. Having given us those particulars as to the voyage, as to the class of coal, as to the place of shipment, and as to the month of the year in which the sailings and the casualties have taken place, have you any statistics to give as to the mode of shipment?—In Liverpool coals are shipped both by hand and by tip. On the Birkenhead side the shipments are by shoots, and on the Liverpool side by a crane that carries the wagon over the vessel; the truck is lowered and then tipped, the coal falling down the whole depth of the hold. In some cases the crane also takes boxes from a truck. There are three boxes generally on a truck, and those boxes are lowered by means of the crane into the hold so that the coal need not get so broken when it is unloaded from the box as when it is tipped from the wagon. The hand loading is by basket and by barrow.

75. Have you any statistics as to the apparent effect of different kinds of loading?—No, but comparing the loading by crane and the loading by hand I have the following: Of the vessels which sailed from the Mersey in the nine months, January to September 1873, 65 out of 189 were loaded by tip, or 34 per cent. of the whole. In the same period for 1874 88 out of 242, or about 36 per cent., showing a very slight increase in the percentage of shipments by tip during the second period.

76. How does that bear upon the result as to casualties?—I have given here the total number shipped by tip, the shipment by tip on the Liverpool side, and the shipments by tip on the Birkenhead side; if we separate the shipments by tip on the Liverpool side from the shipments by tip on the Birkenhead side, the Liverpool side shows an increase in the number of shipments by tip in 1874 of over 75 per cent. which is a significant fact when we remember that the great increase of fires has been in the Lancashire coal shipped on the Liverpool side. The conclusion, therefore, that I would draw is that the shipment of coal by tip breaks the coal very much and increases the danger.

77. (*Mr. Vivian.*) As to the Birkenhead shipments can you tell us what description of coal it was, whether it was bituminous coal or not?—The fires have occurred in North Wales steam coal in each case. There were only three cases; the first was a North Wales steam coal, the particular colliery not named; then there was main coal from the Tryddyn Colliery, Coed-Tallon, and a mixed cargo of Westminster, Brymbo, and Oak pits; that was in the 1874 period. There were no cases of heating in cargoes of coal shipped from Liverpool or Birkenhead in the 1873 period.

78. Can you give us the description of coal shipped from the South Wales ports?—There were ten cases of heating in the 1874 period, one in each of the following: Powel Duffryn steam coal, Insoles' No. 3 Rhondda, Insoles' Merthyr steam coal, Hood's Merthyr steam coal, and six in No. 3 Rhondda coal, which I believe is a smelting coal.

79. Were those to the West Coast of America?—These shipments from the South Wales ports were not entirely to the West Coast; there were three to the East, one to Shanghai, and two to Singapore. In the 1873 period there were seven cases of heating from the South Wales ports as follows: two in Rhondda bituminous coal, one in steam coal (colliery not named), two in Broad Oak bituminous coal, one in Through-and-through bituminous coal, and one in Aber smelting coal.

80. Where was that shipped?—At Porthcawl.

81. Where was the Through-and-through coal shipped?—From Newport.

82. Does that exhaust the whole of the South Wales coal?—Yes, I have given you the whole of the names.

83. Can you give us the same particulars with regard to the Scotch ports?—Beginning with the 1873 period when three cases of casualities occurred, the descriptions of coal were as follows: Wishaw Ell coal supposed to be from the Larkhall district, Townhill steam coal from Fife, and Ell coal from the Wishaw district. In 1874 there were nine cases, viz.: Steam coal, Ell coal, splint coal, collieries not known, Russell's main coal. Then there was a cargo containing four different kinds of coal, all splint coal from these collieries, Woodside field, Hell field, Lougler field, and Skellyton field. Then Watson's Hartley, Auldton Ell coal, Auldton steam coal, and Splint steam coal, colliery not known.

84. Those were shipped from what port?—Some from the Clyde and some from Dundee; the Auldton Ell coal and the Auldton steam coal were shipped from Dundee, and one splint steam coal from Leith, all the other coals being shipped from the Clyde. That was in 1874, and in 1873 the two shipments of Wishaw Ell coal and the Townhill steam coal were shipped from Dundee.

85. Can you give us the same particulars with regard to ports on the east coast of England?—In 1873 out of 13 cases, there was a shipment of each of the following: Harton Wallsend house coal, Davison's West Hartley steam coal, Howard's West Hartley steam coal, Cowpen Hartley steam coal, Featherstone's main second-class large steam coal, West Yorkshire, Featherstone's West Riding steam coal, Yorkshire Hartley steam coal, and three shipments of which I do not know the particulars. Then shipped from London there was Newcastle West Hartley coal in two cases. In the year 1874 there were fifteen cases, viz.: Of Cowpen Hartley, three, of Howard's West Hartley, one cargo of a mixture of both of these, one of Bower's West Hartley, one of Carr's Hartley, one of Ravensworth West Hartley, another of coal described as West Hartley main steam, one of coal Bedside West Hartley, one of Davison's West Hartley steam coal, and one of Hastings Hartley coal; one cargo I have been unable to trace, and this makes the whole for 1874.

86. (*Mr. Cory.*) You have given the number of casualties and the different kinds of coal, can you give also the number of shipments of different kinds of coal?—No. I have only had the number of shipments in 1873 and 1874 from two collieries sent to me.

87. The number of casualties does not very clearly show the comparative liability of coal to spontaneous combustion?—No, unless you know the number of shipments of a particular kind of coal you can scarcely form an idea whether it was a dangerous coal, it might be that that coal was more generally shipped.

88. (*Mr. Fenwick.*) Do I rightly understand you to say that more accidents occurred in iron vessels laden with coals than in wooden vessels?—In the second period there was a greater proportion of iron vessels in the casualties, but it is difficult to say whether it was on account of there being more iron vessels, there was a greater proportion of casualties in the second period. It is noteworthy that out of the casualties in 1874 a large proportion occurred in new ships.

89. Do you give any particulars as regards coal shipped in wooden vessels as compared with coal shipped in iron vessels?—Only with respect to those vessels to which casualty has occurred. In a tabular form I have the particulars of each vessel as well as the kind of coal, on one page the particulars of each vessel and her cargo, giving the names of the vessels, the nationality, the year when built, the class, whether iron or wood, net registered tonnage, depth of hold, number of decks and if laid, tons of coal, description of coal, name of fitters or shippers, and kind of ventilation. Then on the other side are particulars of the voyage and the casualties, giving the date of sailing, the destination, date of the casualty, or when signs of heating were first discovered, the number of days the vessels were out, where the casualty occurred, the nature of the casualty, and some few remarks.

90. (*Mr. Icely.*) Have you any accurate information with regard to the mode of ventilation adopted in the cases of those vessels in which casualties occurred?—Yes, for a number of cases.

91. Have you had any sketches made of the ventilation adopted?—In some cases I have had sketches

Mr.
R. C. Rundell.
June 1875.

made, and I should be pleased to put them in. It is a very difficult matter to say whether a vessel is sufficiently ventilated or not. She may have left the United Kingdom with good arrangements for ventilation, or been prepared for a certain amount of ventilation, and that ventilation may have been crushed in by carelessness in loading. The underwriters surveyors at Liverpool have recommended a certain system of ventilation, and they would be able to give the Commission very detailed information as to the mode they recommend. These surveyors go round the docks and give information amongst other things to the underwriters respecting the mode of ventilation adopted.

92. (*Mr. Young.*) You said if I remember rightly that of the whole number of sailings in the two years one third of the vessels were of iron and two-thirds of wood?—I spoke merely of sailings from Liverpool for the second period when I said that the number of iron vessels which sailed was a third of the number of wooden.

93. You did not tell us how many iron vessels were burnt or encountered disaster?—Eight on the first period and sixteen in the second. Four out of the sixteen Liverpool casualties were in iron vessels.

94. You said that the sailings in June, July, and August were the most dangerous?—We have had the greatest number of casualties in the sailings for those months.

95. You have not gone into a comparison of the number of sailings in those months with the number of casualties?—Yes, I have the date but have not given the percentages.

96. You have taken into account that there are a greater number of vessels actually sailing in those months as well as a greater number of casualties?—I have a table showing for each month of the two periods the number of sailings, and the number of casualties which have been reported out of those sailings.

97. From that you would come to the conclusion that June, July, and August are the most dangerous months?—Yes, the greatest per centage of casualties have occurred in the sailings for those months.

98. I understand that that conclusion arises from a comparison of the whole number of vessels that have sailed, with the whole number of casualties?—Yes, after that I have been able to ascertain.

99. (*Chairman.*) Crossing the Equator?—Yes.

100. (*Mr. Young.*) Throughout your statistics, do I understand that you have as far as possible got the particulars of every vessel that has sailed as well as of every vessel that has had a casualty?—Yes, as far as possible; the per-centage of casualties on sailings of course is the information that is desired. The sailings from most of the coal ports have been obtained from Brown's monthly export lists. In these lists, when more than one vessel has sailed during the month from either port for the same voyage, only the aggregate of their cargoes is given and not the number of tons of cargo belonging to each vessel. In the tables, each vessel is included if the aggregate tonnage of the cargo gives an average of more than 500 tons, and unless the average amounts to 500 tons the vessels are excluded. The tables are thus subject to any slight error which this may occasion.

101. (*Mr. Abel.*) Do your statistics include as casualties only those cases in which important damages have been recorded?—Any case of heating that I have heard of I have included as a casualty.

102. Any case of heating that has come to your notice as having given rise to damage?—There has been scarcely any case of heating that I have had an opportunity of examining, but that there has been some damage more or less; in fact some pecuniary less

103. May we look upon these cases of heating, which are classed as casualties, as giving something like a complete return of the cases of heating and fire that have occurred?—As far as I have been able to ascertain, I think all the published cases, and, I do not know what proportion, but I should expect a large proportion, of those cases that have not been published, perhaps more particularly as far as Liverpool is concerned.

104. (*Chairman.*) Would the cases which you have included in your figures be those in which a claim has been made upon the underwriters?—No, I have not been governed by that; some are cases in which a great amount of heating in the coal has been observed, and where I am unaware of any claim having been made.

105. (*Mr. Abel.*) You have included casualties where there was heating and fire and you have included also cases of heating without fire which have given rise to damage?—Yes, cases where jettison has resulted, where a man has been so alarmed about the heating that he has jettisoned the cargo. I have the details of each case of damage, and extracts from the masters' protests in a great number of cases giving particulars as to what efforts were used by the captain to extinguish the fire or to prevent the heating of the coal, showing that some captains showed great promptness and energy in preventing the extension of the evil.

106. I suppose you have not any data in your statistics which give the relation between the cases of casualties and the price of coal at the time of shipment?—No; where there is a readier market for coal you find that there is then an incentive to send coal for shipment that would not otherwise be sent. I have here some remarks from our agent at Marseilles that rather bears upon that point. In the latter part of the year 1874 there were a great number of casualties in the shipment of lignite from Marseilles for the Mediterranean ports and the agent's remarks in connexion with this was, "That increased demand has "has induced sellers to ship coals immediately after "their arrival from the mines, that is, with a certain "amount of dampness," showing that if they had not had this increased demand the coal would have probably been left at the coal pits some time before shipment. Inquiry was made of our agent with a view to discover if there were any transhipments of English coal from Marseilles, whether these fires had been in English coal. As far as he could ascertain they have been entirely confined to coal from the south of France.

107. I gather that you establish a decided relation between the breaking up of the coal and the frequency of the casualties in the coal shipped?—The breakage increases greatly the surface; for instance, if coal is tipped and much broken, the surface is greatly increased and there is a greater amount of decomposition going on in a limited space.

108. As a fact your statistics show that where the coal was either shipped by tipping or was "through and through" coal, coal containing a considerable proportion of slack, the number of cases of heating was increased?—I think that would be the deduction to be drawn from the statistics I have here, that the smaller the coal the more frequent the casualties.

109. (*Mr. Ferguson.*) As regards the 1,240 sailings in 1874 and the 1,133 sailings in 1873, have you taken any notice of other casualties that happened to those ships other than spontaneous combustion of coal?—No, but there have been cases of stranding.

110. You do not take those casualties into account in your statistics?—No, I have only taken missing vessels; I have, however, noted that in coal laden vessels on these voyages casualties, otherwise than from heating, are rare.

111. Of several vessels missing during that time it might be fair to conclude that some of those vessels might be lost from other causes than spontaneous combustion of coal?—Yes, in the cases I have here of missing ships I have endeavoured to form some conclusion as to whether they were lost by perils of the sea apart from fire, or from fire.

112. (*Mr. Duncan.*) Have you taken any notice whether the coals were single or double screened?—When I have had any information given me as to that point, I have taken note of it, but I have not asked

Mr. R. C. Ruudell.

1 June 1875.

for it specially; if I have had it, it has been given me gratuitously without its being asked for.

113. There is nothing in your statistics which would show whether or not coals double-screened would be less likely to take fire than coals single-screened?—No.

114. You would consider that when coals were carried by the crane over the hatchway and allowed to drop into the hold a greater quantity of small coal would be put on board than if the coal were put on board by barrows?—Yes, the coal would be liable to break more. Some coals are very friable. In "Stevens on Stowage" it is stated that in South Wales it is the practice to dig out a quantity of small coal from the hatch after the vessel has completed her loading, and to replace it by larger coal, showing that there is a feeling that danger may arise from too large a surface of small coal.

115. If they handle coals as I have seen them handle them in Liverpool in the case of the Peninsular and Oriental ships, where the coals are put into barrows, which barrows are lowered into the hold and there emptied, the coal is prevented from becoming broken?—This Company is very particular I believe about the shipping of its coal, and a special agent is appointed to inspect the shipping of the coal, not so much with a view to prevent fire as to prevent the coal becoming broken.

116. Have you been able to make any distinction between ships loaded in that way and ships loaded in the ordinary way by dropping the coals in from the tip?—Yes, and I have a return given me by Mr. Hughes of Liverpool, showing the number of vessels in which he has shipped North Wales coal by hand, showing that they have all arrived safely.

117. Your papers when put before the Commission would give information that would indicate that where coal is shipped in this way by barrow, the coal is not broken so much, the effect of that being to lessen the danger?—Yes.

118. I suppose you are aware that there is a considerable difference between the construction of the new ships and those constructed formerly, that difference having a tendency to affect their ventilation, that is to say, that the stringer plates are brought home to the shell of the ship in place of being attached to the frames as before. Whereas formerly there used to be an opening, now the stringer plate is secured by the angle iron to the shell of the ship and therefore to that extent the amount of space for ventilation is diminished?—The two periods that I have selected being only 1873 and 1874, I do not know that there would be that difference, between 1873 and 1874 in the style of building vessels.

119. You stated that there were a great number of new ships in 1874; the mode of construction to which I have referred of bringing home the stringer plates to the shell of the ship is a mode of construction that has been introduced within the last few years?—Anything that would tend to shut up the coal would naturally conduce to the danger of combustion.

120. That is one of the things that might have some effect in causing coal carried in new iron vessels to burn more readily than in the case of old vessels?—Probably. There is another point with regard to new vessels. It has been stated to me that when a shipowner has a new ship and he wants to load her with coal he asks the builder on what day she will be ready—the builder is always ready to name a day, and replies, "You may depend on having the vessel ready by such a day;" the owner says, "Well if so I will order the coals round." The shipbuilder declares that the vessel will be quite ready by that time and the owner orders the coals. Instead of being ready by that time the vessel may be days and weeks before she is quite ready, and the coal is all the while lying in the trucks exposed to bad weather, and I heard of one case in which coal brought down in that way and kept waiting for the vessel was exposed to bad weather so that the small coal became quite "pasty;" that was the term used.

121. (*Mr. Vivian.*) Did that coal fire?—It went merely from one of the east coast ports to London. I made inquiry about it, but could not find that it heated; it was a short voyage.

122. (*Mr. Duncan.*) You have stated that the coals appear to fire most readily that are shipped in the driest months of the year?—Dampness being one of the elements in spontaneous combustion I made inquiries to see how far the period in 1874 may have been damper than the period in 1873, and I found this to be the result. Taking in each year July, August, and September, when most of the coal cargoes affected by fire were shipped, there appears to have been no appreciable difference in the amount of rainfall in North and South Wales during these two periods, while in Lancashire, and Yorkshire, Northumberland, and Scotland those months were decidedly drier in 1874 than in 1873.

123. So that according to that it would seem that exposing them in the waggons does not do them any harm?—Not for these periods, so far as rainfall is concerned, but the coal may have been worked damper in 1874 That is another point; the surface seams in Lancashire (in this I am only speaking from hearsay) are damper than the deeper seams, but I have not heard that they were more worked in 1874 than in 1873. With regard to the coal from the seams in Lancashire I heard that some old seams that had been out of use for some time were reworked in 1874.

124. And those workings were all the time standing full of water?—I have no information upon that point.

125. You would not infer that there would be more coals brought in June, July, and August than in other months of the year?—No, not as a rule. In 1873 more vessels sailed in the previous three months.

126. (*Chairman.*) May the Commission take it as the upshot of your evidence that the casualties from spontaneous combustion of coal afloat are on the increase?—There is a great increase in 1874. As regards a comparison between 1873 and 1872, I could not give the result, as to the per-centage of casualties on voyages, but only approximately from a table I have here as to the number of casualties; I think I mentioned before that the number of casualties from 1868 up to the end of 1873 were 65, while the number in 1874 alone there were 64 cases, showing that for seven years we have the same number as in 1874.

127. From the knowledge which you have derived from your connexion with the Underwriters' Association of Liverpool, would you say generally that casualties were on the increase?—No, I should say not; there have been scares; as far back as 1867 there was a great deal of talk about spontaneous combustion of coal, and underwriters gave some particular attention to it, but since that I think premiums, so far as I have been able to judge (I have only limited experience in that matter), have not increased till last year.

128. During a series of years, up till last year, premiums were pretty steady?—As far as I know.

129. In this year they have risen?—They have risen from 25 to 75 per cent.

130. So far as the figures you have produced may be relied on, they have risen with justice; they are in consonance with the actual results?—Yes, but when the underwriters hear of a great number of fires occurring they are unable to tell, without going into a calculation of this kind, what the per-centage would be on the sailings, so as to estimate the risk, and therefore each one is left to himself to form an idea what would be a safe premium.

131. The per-centage on the sailings of 1874 is very much higher than the per-centage on the sailings of 1873?—100 per cent.

132. That is understood and acted on by the underwriters?—Yes.

133. They have not yet got before them those details which you have been working out, still the general results are tolerably well known?—I do not know what effect those statistics may have in altering

Mr. R. C. Rundell.

1 June 1875.

the rates of premium. I do not know that they will have any effect, but each underwriter has been forming his opinion during this period, and I understand that generally the rates have somewhat declined of late; they consider that coals are safer now than they were in 1874.

134. Looking at the fact that for a good many years before 1873, so far as you can judge, there was no seriously increased per-centage of casualty, and that that per-centage seems to have suddenly increased in 1873 and 1874 and is now going down again, does not it look as if the proportion of casualties had a good deal to do with the increased demand and to the consequent want of care in the selection of coal?—Yes, I think that is a very natural deduction to make.

135. So far as you can judge, the casualties are not so much the result of carelessness on board, or in the appliances of the ship, as of want care in the selection of the coal and an absence of proper precautions in the shipment of the coal?—The information I have obtained appears to lead step by step to the conclusion that the increased number of casualties from spontaneous combustion proceeds from the condition in which the coal is shipped, and the coals shipped in 1874 were most probably not so free from pyrites and small coal as in the case of the coals shipped in the preceding years.

136. The very large increase in the demand for coal, compared with the supply in 1874, would account for coal being shipped that would be liable to take fire?—The coal agents found a market for the inferior coal, they were able to sell and get rid of.

137. Have you considered at all whether there is any connection between the increased amount of casualty, and the increased want of control over the men who are concerned in handling the coal?—No, I have only gone into the labour question as far as this, that for the last two years there has been a great increase in the cost of labour, and consequently there has been an inducement to curtail, as far as possible, all labour beyond that required to get and deliver the coal. The Coal Mines Regulation Act which came into force on January 1st, 1873, has also made one source of cheap labour less available. By this Act children are not allowed to work at the mine, except under certain restrictions, which have had the effect of gradually removing a great many of those who were formerly employed in cleaning and selecting the coal, and the remainder of the children, I am told, have thus been able to secure an increase in their wages of nearly 100 per cent. And then with regard to demand, there has also been a great demand for coal and a ready sale has been found for inferior and unclean sorts which would not formerly have been marketable.

138. That again is an element on shore and not afloat?—Yes.

139. Have you considered whether this also may not be an element, the diminished control over the men in the collieries, the men sending up coal which they ought not to send up and ought to throw aside?—I have been told this, that formerly men were fined for sending up bad coal, but that they are not fined for doing so now. The pitmen, it is stated, would have been fined for sending up so much bad stuff, and the stony and metallic part of the coal which did come up would be carefully separated at the pit's mouth. Now, the coal agent, in order to meet the demand, appears to accept anything passed to him.

140. So, summing it up, you, whose special function it is more to observe what happens afloat than what happens ashore, and who would be the first to mark if there was anything serious going wrong afloat, do not attribute either to the construction of the ships or to the management of the coal ships, or to the selection of the coal ships, the increased proportion of casualties, but you rather attribute it to what occurs before the coal is shipped?—Yes, greatly. There may be some other causes that help to make the increase larger, but I think the great cause for the increase arises from the condition of the coal before it goes on board.

141. A question was put to you as to the construction of coal ships, and you said on one point the more modern construction may lead to greater danger than before, by its interference with the ventilation?—I was not aware of the fact of my own knowledge, till Mr. Duncan mentioned it, but I think that would bear on the ventilation of the cargo.

142. Do you think that the class of ship that is being employed for carrying coal on these voyages is a worse class or a better class than it used to be?—I have not very great experience in the matter, but I should fancy that other freights being lower a better class of vessel is employed in the shipment of coal on long voyages than formerly.

143. The popular impression is that any ship would do for coal, but so far as those voyages you have been analysing are concerned you do not think that impression is borne out by the facts in recent years?—No, the casualties have been in high class ships. I am told as regards a number of American vessels that go from Liverpool which used to carry coal, the owners in America are sending them now with salt in preference to coal on account of the increase in the premium.

144. With regard to the owners of the ships which are used in the coal trade for those longer voyages, speaking generally you see no foundation for any imputation that they are less careful than they used to be in the selection and in the handling of those ships?—I have no reason at all to suppose so from what I know.

145. You attribute the increased proportion of casualties to what occurs on shore not to what occurs afloat?—Yes.

146. You have analysed the voyages of the larger ships on the longer voyages crossing the Equator, have you any general facts as to shorter voyages?—I prepared some preliminary statistics taking in North Atlantic voyages as well as South Atlantic voyages, and I limited it at first to all vessels taking above 100 tons of coal. I then prepared another series of statistics giving vessels which had taken 250 tons of coal and upwards.

147. Could you give us the general impression in your own mind of the result?—My impression from those statistics was that a greater number of casualties occurred in voyages across the Equator, and for that reason in subsequent investigations I limited myself to those longer voyages.

148. Is the general impression on your mind that casualties are on the increase on the shorter voyages?—I am not able without reference to say, but my opinion is from recollection that they would show about the same great increase in 1874 over 1873.

149. You think that the longer voyages are a good specimen of the whole trade?—Yes.

150. What would you call the average voyage of a sailing ship to New York for instance?—About 30 days.

151. And to the West Indies?—To the West Indies, say St. Thomas you might put on five or six days; where they are going south they get finer weather sometimes, the length of the voyage also depends on the class of ship.

152. They come within the period in which a considerable number of casualties occur according to your statistics?—Yes.

153. So far as you have carried your inquiry you have not seen any reason to discriminate between the longer voyages and the shorter voyages?—Time is an element, but I think the same thing which would operate to give the increase on the longer voyages would operate to give the increase on the shorter voyages, that is the condition of the coal.

154. Have the premiums risen in equal proportion?—Yes, irrespective of the voyage, that is, taking it apart from its character as a marine risk.

155. The premiums have risen in the same pro-

Mr. R. C. Rundell.

1 June 1875.

portion for the short voyages as for the long voyages?—Yes.

156. As to the mere coasting trade, do many casualties from fire, as far as you know, occur in the colliery coasting trade?—I am not prepared to give any information upon that.

157. (*Mr. Vivian.*) You were asked as to the shipping of coal in barrows, is not it a much longer process to ship coal in barrows than in the ordinary way by tips?—It takes considerably longer.

158. Is not it the case that vessels have frequently only a certain number of days allowed them to load?—Yes, a vessel going under the tips at Liverpool, that is to say, at the cranes, can load, I am told, as much as 800 tons a day.

159. How many tons a day do you think a vessel could load with barrows?—A vessel of 1,200 tons would take I believe 10 or 12 days.

160. What number of days is a vessel usually allowed for loading?—I have no information upon that point.

161. It would take, perhaps, very nearly five or six times as long to load by barrows?—I should think that would be about the time.

162. She would be occupying dock space all that time and incurring other expenses?—Yes. With respect to shipments in South Wales, I was told the other day by a shipper who had had some experience in shipping coals there, that the shipments were sometimes very hurried, and occasionally it was to the advantage of the coal agent that the shipments should be hurried. For a consideration a coal shipper will undertake to load night and day, so that a ship may go off on a tide. I was told that it would be from 50*l.* to 100*l.* more in the coal shipper's pocket by shipping the coal off quickly, and I think Mr. Duncan knows a case where 300*l.* has been paid to hurry the vessel forward.

163. That would be inconsistent with shipping the coals in small quantities by barrows, would it not?—Yes, it would have to be done by tip.

164. Are you aware that there are some drops in South Wales in which boxes are used?—No, I have no information except from hearsay with regard to South Wales. On the Liverpool side they have boxes lowered into the hold of the vessel.

165. Do you know at all how the coal has turned out which has been shipped by boxes?—No, the returns I have been favoured with only give the number of vessels loaded under the crane; the crane may lower the wagon, which is then tipped, and the coal may fall down the whole depth of the hold, or it may have a box from a truck slung to it and this box can go into the vessel. You can only say that it has been loaded from the crane, or loaded from the high level, as it is termed.

166. Frequently a vessel is loaded partly in one way and partly in another, is it not?—I do not know.

167. Is it not the case that sometimes a column of coal is formed in the hatch by boxes, and subsequently the coal is tipped from the wagons upon that?—Those that are careful might possibly make arrangements of that sort.

168. The wagon itself is lowered just over the hatch?—Yes, as near as can be.

169. It is quite as much to the coal owner's interest to preserve the coal from breakage as it is to the interest of the person who purchases. I presume the character of his coal depends on its size?—Of course those coal agents who have a name to keep up are desirous that their shipments should turn out satisfactorily.

The witness withdrew.

Captain J. Scurr.

Captain John Scurr examined.

170. (*Chairman.*) You command one of the ships of Mr. Ferguson, who is a member of this Commission?—Yes, the "Brenhilda."

171. You have carried several cargoes of coal?—Yes, two as master, but I have carried several half cargoes, and at one time when I was a seaman we carried an entire cargo.

172. The last voyage of the "Brenhilda" was your third voyage, was it not?—Yes, the second as master with an entire coal cargo.

173. On the previous occasions had you any trouble with your coal?—None whatever.

174. On the last occasion had you some trouble?—Yes.

175. Will you explain to the Commission what happened?—I found the coals got heated very much in the fore hatchway. The ship is wonderfully well ventilated; it has all the new improvements in ventilation; there are three large ventilators, one in each hatchway, coming from the keelson right up, wooden ventilators with holes pierced right through at intervals.

176. Your voyage was from where to where?—Glasgow to Calcutta.

177. When did the "Brenhilda" sail?—She sailed from Glasgow on the 23rd June 1874.

178. Where were you when you first experienced that heating?—Between the Tropics and the Equator.

179. Between the northern Tropic and the Equator?—Yes.

180. When you were between the northern Tropic and the Equator you first noticed this heating?—Yes.

181. About how long had you been out?—I should say it was 40 days. I had a long passage.

182. What did you first observe?—I observed a heating in the coals, and a strong smell of gas coming out.

183. In what part of the ship?—The forehatch.

184. What did you do?—I turned the coals over. I took the heated coals out, and endeavoured as well as I could to get to the cool coal. I took 20 tons of coals on deck to let them cool and put them in the fore peak.

185. How long did that take?—I daresay three days.

186. After that had you any further trouble?—I looked at them from time to time and turned them over.

187. Was there any coal between decks?—Yes; there was coal between decks as well as in the hold, but there was no heating between decks. It was all down in one place in the forehatch. The heating was just under the forehatch, between the afterpart of the forehatch and the foremast. We turned the coal over till we got to the cool coal.

188. And you replaced it in about three days?—Yes.

189. After that before you got to Calcutta did you notice any heating again?—No.

190. Did you take any precautions after you observed that heating?—Yes, we went and turned the coal over from time to time.

191. Between decks the coal never heated?—No.

192. What arrangements had you for ventilation?—We had three ventilators; we had one ventilator in the forehatch, and one in each of the other hatches.

193. What was the depth of the ventilator in the forehatch?—It went right to the keelson; that would be about 22 feet.

194. What did it ventilate into?—Into the hatch.

195. When the hatch was down what did it ventilate into?—The other ventilators would then carry off any foul air.

196. Supposing there was smoke or gas escaping, how would it get from the ventilator in the fore hatch to the other ventilators; I mean when the hatches were down how would any ventilation take place through the coal?—The coal was 3 feet from the 'tween decks. The ship was not full of coals; she was empty from the fore part of the fore hatch. The coal did not reach within 3 feet of the upper deck.

197. At all times and in all kinds of weather,

Captain J. Scurr.

1 June 1875.

whether heating was going on in the coals or not, would the ventilators reach the outer air?—Yes; we always kept the permanent ventilators open in any kind of weather.

198. (*Mr. Young.*) Had they the cowls on?—No; they are a sort of skylight, they are sloping. The masts are ventilators as well, they are iron masts.

199. (*Chairman.*) You reached Calcutta without further accident?—Yes.

201. Had you any trouble with your coal there?—Yes.

200. Will you describe what happened?—We discharged some of our cargo from the main and after hatches, and on the Saturday we found a dense smoke coming up. That was as soon as we got well down in the main hatch and the after hatch. A great draught seemed to come from aft, the wind being from north-east, causing a greater draught, and the coal seemed to ignite.

202. Will you describe what happened; what were the first symptoms of anything being wrong?—After discharging about 500 tons, the draught got into the ship and we noticed a strong smell of gas, we could not go into the fore hatch. The moment I found it out I got boats alongside, and got a lot of coolies to come on board, and I put canvas on the coolies' feet and set them to work on the coals. I put the steam donkey pump and the force pump down into the hold, keeping them constantly at work, and I kept the hose down the ventilator. I found that there was still a smoke, and that what I was doing was not sufficient to put out the fire, and I went to the port conservator and got him to let me have the steam float alongside, in case of further mishap, on account of being among a number of ships.

203. Was much water sent into the ship?—Four feet of water in about half an hour.

204. Then you got the coal out?—Yes.

205. In what state did it come out?—I should think 5 tons of this coal was taken out (*producing a specimen*) 10 feet below 'tween decks about 6 feet from the keel. It seemed to be in the middle of the fore hatch.

206. You took this coal in at Glasgow?—Yes.

207. How would you describe that coal from its look?—As half cinder, resembling coke.

208. Quite light?—Yes; there were 3 or 4 tons of that.

209. It had been in a state of half combustion long enough to reduce its weight to very little more than coke?—Yes.

210. Is it your impression that from the time when you had the indications of fire, near the Equator till you reached Calcutta, that coal had been burning?—I fancy so, on account of the heat being still in the same place; it was only 5 feet from where I found the previous heat, this was in the centre of the fore hatch, the other was between the fore hatch and the foremast.

211. What in your opininion saved you from worse disaster, was it the goodness of your ventilators?—I cannot fancy that because on previous occasions I had no trial of ventilators at all. It is a guess of mine, but I think the cause of the casualty must have been in the coals, because in some of the pieces I took up there was a stronger heat in the middle of the pieces of coal when I broke them than on the outside. I am speaking of pieces of 70 lbs. or 80 lbs.

212. Would it be your impression that it was the impossibility of any air getting to the coal that saved you from the like casualty on former occasions?—I would not like to say.

213. To go back to the coal itself, you say you sailed from Glasgow, do you know where the coal came from?—It was called Watson's coal in the bill of lading, that is all I know about it; I could not say from what colliery it came.

214. Do you know anything about the time it was in reaching you from the colliery?—It was a very short time.

215. Was it run down to the ship by rail?—Yes, the coals were taken in in four days.

216. They were put in at once?—Yes.

217. The coal was not standing a long time before you took it?—No.

218. The trucks were run straight to the ship?—Yes.

219. Was there a large proportion of small coal?—No, it was principally large.

220. Was it well picked as usual?—Yes.

221. It was not worse coal than you had had on former voyages?—No; on the former voyages I took 600 tons of small coal with large coal for Bombay.

222. What you were taking this time professed to be large coal?—Yes.

223. You knew nothing about it except that it went on board very quickly after it came from the pits?—Yes.

224. How was it put into the vessel?—By a steam crane which lifts the trucks up and tips them into the ship, we would not let them drop the coal far down.

225. It was carried by a crane and tipped. How high would the trucks be when they were tipped?—I should think 4 feet from the deck.

226. Did it seem to break very much in falling?—No, very little.

227. Did you notice whether it was damp at all?—It was perfectly dry when it came in; it was beautiful weather at the time, there was not a shower of rain.

228. It was at midsummer?—Yes.

229. Had you very dry weather going out?—I always tried to keep the coals dry, I would not let any wet get to them.

230. Had you any bad weather?—No, it was middling good.

231. Was it very close between the tropics?—It was very warm.

232. Was the air very highly charged with moisture?—Yes.

233. Were you hanging about in the tropics a long time?—Yes, I should think it was three weeks before we got the south-easterly trade. It was indifferent weather, the winds were contrary.

234. (*Mr. Vivian.*) Is the "Brenhilda" a sailing ship?—Yes.

235. (*Mr. Duncan.*) Do you know whether or not the coals which took fire in the forehatch were the same description of coals as those in the other part of the vessel?—They were the same, I believe.

236. Do you know of any reason why the coals in the forehatch should take fire any more than the coals in the after-hatch?—No, I do not know why they should; the coals which took fire seemed to be more charged with gas, they seemed to be a slatier coal, when you broke a piece it broke clean like a slate.

237. Did they look like the coals from which they get oil?—They had not any of that appearance. They seemed a slatier kind of coal.

238. You do not think that any water went down the fore-hatch by accident or otherwise?—No, I took great care of that. I always endeavoured to keep the coals quite dry.

239. At the time that you put out the fire in the fore-hatch when you were at Calcutta, by the means which you adopted, did you find the other coals quite cool in the lower hold?—Yes, all except in that one spot. They were a little warmer under the after-'tween-decks, but I attribute that to the want of circulation of the air on account of the weather. It was raining heavily at the time I was in Calcutta, that is to say, on the Saturday and Sunday.

240. (*Mr. Ferguson.*) Were there any other vessels loading coal at the time you were loading?—Yes, the "County of Perth" was loading.

241. Was the "Blair Athol" loading?—No.

242. Was she after you?—Yes, the "County of Perth" took all her coal over at Stob Cross by barrow.

243. Was that the same coal?—Yes, I believe so.

244. She loaded by barrow while you loaded by tip?—Yes.

245. Are you aware that the "County of Perth"

Captain J. Scurr.

June 1875.

was burnt ?—Yes, she took fire near Calcutta about 100 miles from Sand Head.

246. The "Blair Athol" took fire at Bombay ?—Yes.

247. She was loaded just after you ?—Yes.

248. With what kind of coal ?—I fancy Watson's Hartley.

249. During the time you were loading was there any rain at all ?—No.

250. (*Mr. Abel.*) When you first found that this heating had taken place in the coal you went down as far as the heated portion went ?—Yes.

251. Did you take out all the heated coals ?—Yes, and turned them over.

252. You went down to the perfectly cool coal ?—Yes.

253. Till you could feel no sign of heat whatever ?—Yes.

254. On both sides ?—Yes.

255. When the coal had got cool again did you put it back in the same place ?—We lifted 15 or 20 tons and filled the coal hole up with them. I thought that was the best thing to do. We kept it for the ship's use. There was 20 tons on the bill of lading for the ship's use, so I did not put it back as I thought it would be a good opportunity to use it.

256. Was other coal shifted into the place from which you had taken out that coal ?—It was just trimmed, and we left a vacant space in case of any more turning up.

257. I understand you to say that on the second occasion when the fire was discovered it was about the same place in the ship ?—A little before the same place, about 5 feet before.

258. But at the time when you first observed this heating you examined the coal generally ?—Yes, from time to time.

259. And you did not discover any other sign of heating ?—No.

260. Did you shift the coal at all after that from time to time during the voyage ?—No.

261. You did not assist the ventilation in any way ?—No. I did not think the ship required it, because she was so well ventilated all round. The air could get all round the lower hold, and also 'tween decks.

262. I thought you said that it was only in unloading the coal after you had got down to a certain point when the air began to get to the coal that you noticed the fire ?—Yes, that was in Calcutta.

263. Had anything been done between the two periods to stop the ventilation ?—On the second occasion there was a wind from the north-east, which caused a great current of air to go through.

264. That would look as if there was very little ventilation through the coal ?—As regards the body of coal I could not say. In the lower hold she was not sufficiently full in the wings or in the 'tween decks to stop ventilation.

265. So that the air circulated round the coal, but did not seem to penetrate through it ?—Not through the body of the coal.

266. What time elapsed between the discovery of the heating, and when you afterwards unloaded ?—Eleven weeks.

267. And you think there was no heating or fire at the time you replaced the coal, when you filled up the space after the heat was discovered ?—I did not fill up the space; I left it open.

268. Then there was increased ventilation to that extent at that part ?—Yes. At the time of the heating of the coal in Calcutta the principal rush of the smoke and the gas was up the ventilator.

269. Have you any reason to believe that one part of the ship was better ventilated than the other ?—None whatever; it was ventilated right through.

270. Was the size of the coal much the same throughout the cargo ?—The same.

271. There was very little more broken, or no more broken, in this particular lot than the other ?—It was about the same.

272. You think the character of the coal was somewhat different ?—I think so. It seemed a slatier kind of coal in the fore-hatch; it might have only been a truck or two.

273. (*Mr. Young.*) You say the ventilators were wooden ventilators ?—Yes.

274. Was there any sign of charring upon them when you got them out of the ship ? — None whatever.

275. When the fire occurred you did not find gas and vapour coming from the ventilator itself ?—No.

276. The smoke came from the body of the coal ?—There was a sort of steam came up the ventilator from the water going down.

277. I mean before that ?—It seemed to come right up the fore hatch.

278. There was no draught in the ventilator ?—No.

279. (*Mr. Icely.*) Is this (*pointing to the sketch*) a moveable cowl attached to this ventilator ?—Yes.

280. Did you trim it according to the direction of the wind ?—We always trimmed it off.

281. So as to be a down-cast or an up-cast ?—It was an up-cast for the gas to go up.

282. Were these ventilators in the hatchways always open on the top, or did you only open them occasionally when the weather would permit ?—No they would come up to here (*pointing to the sketch*). This ventilator was placed on the fore part of the hatchway.

283. Did the ventilators come through the hatchways ?—No.

284. Therefore, they were not up-casts except when you took the hatch off ?—That is so.

285. (*Mr. Cory.*) Though they do not come through the hatches they are always open, are they not ? The ventilator is still a ventilator though the hatch is closed ?—Yes.

286. (*Mr. Icely.*) Are you certain that there was a space between the deck here (*pointing to the sketch*) and the surface of the coal ?—I could travel from this coal right along to the fore hatch.

287. And these (*pointing to the sketch*) were constantly open ?—Yes, in whatever weather. In fine weather they were all open. These hatches (*pointing to them*) were all off. There are four sections of hatches between decks. I took the precaution of keeping them all off.

288. (*Mr. Ferguson.*) Had you the wing hatches off as well ?—Yes ; and the mid-ship hatches too. I stood them up against the side of the ship.

289. (*Mr. Icely.*) Was this (*pointing to the sketch*) an up-cast ?—This was a down-cast.

290. Could you get the air down there ;—Yes, when it did not rain. The moment it came on to rain we turned it off.

291. This ventilator with the cowl was used as a down-cast ?—Yes.

292. And this as an up-cast ?—Yes.

293. Were these masts also utilized as up-casts ; are there perforations in the masts as well ?—Yes. Then in our lazarette there was a grating that was always off, which caused a great draught. The rush of air was through here (*pointing to the sketch*).

294. (*Mr. Ferguson.*) Had you your hatches often off ?—Yes ; always when it was not raining.

295. During what portion of your voyage had you them off ?—During half the passage they were only put on at night, but the flap of the booby hatch was always down.

296. (*Mr. Icely.*) How did you ascertain that the cargo was becoming heated ?—You could tell by the heat and smell the moment you went down.

297. You did not take the temperature by the thermometer ?—No, In fact it was a thing I forgot to take with me.

298. Is it the custom to take a thermometer in ships ?—Not that I am aware of.

299. Or to test the temperature in the hold in any way ?—Not that I am aware of.

300. Do you think if the temperature of the cargo were tested at different points throughout the cargo,

Captain J. Scurr.

1 June 1875.

the means of discovering the seat of the fire would be afforded?—I dare say that might be done. It is one of those things that masters and mates, I am sorry to say, do not think of till it breaks out upon them.

301. You found the seat of the fire by walking along the deck and finding that it was hotter in one place than another?—Yes, I found smoke rising there (*pointing to the spot*). We could get right over the coals fore and aft. We could see anything rising in the way of smoke and gas.

302. (*Mr. Fenwick.*) What was the quantity of your cargo?—1,776 tons.

303. Was your vessel built of iron or wood?—She was an iron ship. It was her first voyage.

304. (*Mr. Cory.*) Upon the whole do you think you are better without ventilators or with them?—I think I should be just as well without them, looking at the way in which the ship is ventilated in other respects.

305. (*Mr. Vivian.*) Have you often carried cargoes of coal?—No, only on two previous occasions. I have several times carried half a cargo of coals.

306. On the previous occasions did you have ventilators?—None whatever.

307. Was the coal which you carried on the former occasions the same description of coal?—No, it was from the north of England.

308. If you had to load this same description of coal would you prefer to have ventilators or to have no ventilators?—I should leave that to my owners.

309. What would be your own judgment about it?—I am not able to give a confident opinion upon it. But speaking for myself, I would as soon go to sea with a ship that was not furnished with ventilators as with a ship that had them, provided then a stream of air got to the coals, or if the coals had been loaded out of barges.

310. That is to say, if they were put on board gently?—Yes, if they were taken from a craft alongside.

311. And lowered down into the hold?—Yes.

312. So that they would not become too dense in the ship?—Yes, I fancy myself from what I have heard that the heating of the coals is due to the coals coming direct from the pits into the trucks?—A sufficient time is not allowed for the gas to escape from them as used to be the case a few years back.

313. Will you give us the exact history of the occurrence of the fire at Calcutta. When did you commence to discharge?—On the Tuesday I broke bulk, and on the Saturday evening following we observed the smoke.

314. From the Tuesday to the Saturday the hatches were off and the cargo was ~~being~~ discharged?—Yes.

315. Was it being discharged at all the hatches at once?—No, from the main and after hatches. I was discharging from the after-hatch by coolies, and from the main hatch by the steam winch. The fore hatch was untouched.

316. That went on during the period between the Tuesday and the Saturday?—Yes.

317. How much coal was taken out between the Tuesday and the Saturday?—I should think 500 tons.

318. A freer circulation of air must have been caused after that quantity of coal was discharged?—We were well down in the main hold then.

319. You were well down in the main hold before the fire occurred?—Yes.

320. And consequently more air must have passed down?—Yes.

321. Then on the Saturday evening a dense smoke occurred?—It was slight on Saturday evening, then it increased on the Sunday.

322. Did you between the Tuesday and the Saturday examine the main hatch at all?—No.

323. Then you did not know whether the heat was gradually increasing during that period?—I could not say.

324. Your attention was attracted to the smoke rising?—Yes, on the Saturday evening the night watchman came and reported that there was a strong smell of gas, the fore hatch was off then. When the rain had ceased the the hatch was taken off to allow it to get cool, but he reported that there was a strong smell of fire coming up the fore hatch.

325. Did you smell it?—I went and smelt it.

326. What was the smell like?—A strong gasy smell.

327. Was it anything like ordinary gas?—It was a sulphury smell, a stifling smell.

328. Like a sulphur match?—A very stifling smell.

329. Was it anything like the smell when an ordinary fire-place is smoking?—No, nothing like it; it affected your breath, it was a stifling smothering smell.

330. What occurred after the Saturday evening?—On Sunday I could not do anything. I was going constantly to and fro. I found that the smoke and heat was increasing, and on Monday morning I got the donkey engine and the force pump to work and put down the hose, and as soon as I thought the office of the port conservator would be open, I went to the port conservator and got the steamfloat alongside.

331. By that time what was the condition of things?—It was getting worse and worse.

332. There was more and more smoke coming?—Yes, the steam donkey pump and the force pump were not sufficient to keep it down; they kept it down to a certain pitch, but the floating engine put it out instantly.

333. If you had been at sea you would only have been able to use your donkey engine?—Yes, the donkey pump, the head pump, and the fire engine.

334. Would they, in your judgment, have been sufficient?—Yes, I think so, if I had turned all hands to putting out the fire.

335. You think you would have had pumping power enough to extinguish the fire?—I think so, only as this fire-engine is kept on purpose at Calcutta I thought I might have the use of it. If I had been at sea we would have strained every nerve to put it out ourselves.

336. You said that on breaking some of the pieces of coal which were comparatively cool outside, you found that they were in a state of ignition inside?—There was a strong smoke arose when one of those pieces was broken.

337. You exposed more surface in breaking it?—It did not feel so warm outside as inside; it was only in some of the pieces of coal that we observed that. As the men passed them up, I saw a smoke rising from them, and I broke them on deck.

338. Do you think it possible that that coal had been submitted to the action of water outside, which had cooled the external surface, and had not cooled the inside of the coal?—I don't think it. I was very cautious not to let any wet get to the coals.

339. Are you speaking of when you turned over that coal at sea, or of the occasion when you discharged part of your cargo in Calcutta?—When I turned the coal over at sea I found this smoke.

340. And then you found the blocks of coal were cooler on the outside than in the inside?—Yes, if you struck them they would all fall to a crumble, and there was much heat inside.

341. Was there much small coal?—No.

342. The bulk of it was large coal?—Yes, ordinary sized coal, there were some very large pieces among them.

343. Did you find pieces of 20lbs. weight, for instance, in a state of heating?—No. I tried one or two pieces when the men were passing the coals up, and I let them lie on the deck to cool till I put them down the fore peak.

344. Did you remark any brassy look in the coal?—No. I did not notice that there was a shiny appearance.

345. A black shiny appearance; not a yellow appearance?—There was some of that on the coal too;

Captain J. Scurr.

1 June 1875.

there were gold looking streaks in some of it. I did not notice it in that which I broke, but I saw some of that on the coals like a vein of gold.

346. Was there more of that in the portion of the coal which was on fire in the fore hatch than there was in the other portions ?—I did not take notice of that.

347. (*Chairman*). Do you know iron pyrites when you see it ?—No.

348. Your impression is that the cause of the heating of the coal was its being brought too rapidly from the bottom of the colliery into the ship ?—Yes.

349. The coal you had been accustomed to take before had been exposed to the air longer ?—Yes.

The witness withdrew.

Adjourned to Tuesday next at 12 o'clock.

Tuesday, 8th June 1875.

PRESENT :

THE RIGHT HONOURABLE HUGH C. E. CHILDERS, M.P., IN THE CHAIR.

FREDERICK AUGUSTUS ABEL, Esq., F.R.S.
RICHARD CORY, Esq.
GEORGE DUNCAN, Esq.
JOHN FENWICK, Esq.
JOHN FERGUSON, Esq.
CHARLES ICELY, Esq.
JOHN PERCY, Esq., M.D., F.R.S.
WILLIAM YOUNG, Esq.
J. M. CARMICHAEL, Esq., Secretary.

Mr. CHARLES TULLY examined.

Mr. C. Tully.

8 June 1875.

350. (*Chairman.*) You are a shipowner at Newcastle ?—Yes.

351. I believe you have had some experience of cases of spontaneous combustion or explosion on board your ships ?—I have.

352. Have you a large fleet ? — We have 19 altogether.

353. Are many of them employed in the coal trade ? —The whole of them are employed in the coal trade.

354. And I believe within the last few years you have had more than one instance of spontaneous combustion ?—We have had two vessels burnt at sea.

355. One as far back as 1865 ?—Yes, 10 years ago.

356. And the other more recently ?—The other was in January 1873.

357. Are those the only instances that have occurred in your own fleet ?—They are.

358. Will you give the Commission some information about the first case ; what was the nature of the casualty ?—The ship was loaded with smelting coals from Swansea bound to Valparaiso. She was properly ventilated, because in West Coast charters we have always been bound to ventilate the coals properly, as smelting coals are more likely to take fire than steam coals. When she got off the river Plate the men felt the heat, and it gradually got worse and worse till she burned altogether. That was after she had been 60 days out.

359. Have you any recollection of the manner in which the coal was put on board ?—It was put on board in the usual manner, but I believe it was during wet weather.

360. Was it tipped ?—It was tipped in the usual way at Swansea.

361. Do you remember what the condition of the coal was when it came on board ; was there any objection to it on account of its dampness ?—I cannot remember that.

362. Was there any suspicion that the coal contained pyrites ?—It was just the same as the ordinary smelting coals ; they are very full of gas.

363. Will you describe how the ship was ventilated ? —At the present time they have iron ventilators, but we had wooden ventilators like spouts, which communicate with different parts of the vessel. These ventilators come up to the hatchway.

364. To each hatchway ?—To each hatchway.

365. When the hatches were down did the ventilators act ?—They would only act to a certain extent.

366. So that in bad weather when the hatches were down the ventilation would be imperfect ?—Yes.

367. Do you recollect any other special circumstance connected with the casualty which would tend to indicate the cause of it ?—No ; not any further than the nature of the coals. Smelting coals are very full of gas.

368. Was the ship totally destroyed ?—Yes. The fact was the men could not do anything with her : they had to come out of the cabin at last, they felt the heat so much. The ship took fire gradually, and the men had to leave her.

369. (*Mr. Duncan.*) Had your ventilators any connection the one with the other : had you any trunk below connecting the ventilators ?—Yes ; we had the trunk that we carried the copper ore in on our return voyages.

370. You had a double bottom ?—Yes.

371. Was each ventilator put through that double bottom ?—Yes, the ventilators were put through the double bottom.

372. Did they endeavour to put water down the hold ?—Yes.

373. They poured water down the ventilators, and did everything they could for some time ?—Yes.

374. (*Mr. Ferguson.*) Do you know whether the hatches had been much off during the voyage ?—Not expecting to be asked that question, I did not ascertain that, but I should think that during fine weather they would be off. We generally give instructions to that effect, that whenever it is possible to have the hatches off they are to be off.

375. Had she a permanent ventilator ? — Not through the deck. When the hatches were on there might be a little ventilation, but it would be very imperfect.

376. Was she a wooden or an iron vessel ?—Wooden.

377. What was her size ?—460 tons register ; she would carry about 700 tons.

378. She would have 15 feet depth of hold ?—She would be more than that ; she would be 17 feet I should think.

379. Was she filled with a full load of coals ?—Not quite a full load.

380. (*Dr. Percy.*) Do you know from what colliery the coal came ?—I cannot say.

381. Was it small coal, like slack ?—Yes.

382. There was not much lump in it ?—No, it was smelting coal.

383. Smelting coal is what we should call slack ?—Yes.

384. I suppose it would be difficult to ventilate a mass of slack ?—Yes, very difficult.

385. (*Mr. Abel.*) Have you been in the habit of shipping this particular coal ?—We have been years in the trade, and all the time that we have been in the trade we have been shipping the same class of coal.

386. Have you any reason to believe that there was anything exceptional in this particular cargo of coal ?—No, except that I think the weather at the time was very wet when they were shipped.

387. You are not aware whether the coal had been

Mr. C. Tully.

8 June 1875.

long exposed before shipment?—No, I could not say that.

388. (*Mr. Young.*) What was the name of the ship?—The "Morning Glory."

389. Were there any premonitory symptoms of fire; was there any smell of fire or gas beforehand?—If I remember rightly, the men for some days before felt that there was some fire about the vessel.

390. That is to say, they noticed the heat coming up the ventilators?—Yes.

391. Were the ventilators showing any signs of charring?—Very probably.

392. (*Mr. Icely.*) Were your men in the habit of taking the temperature of the coal by a thermometer? —No, I do not think they were at that time.

393. That has never been the practice?—No, it had not been the practice as far as we were concerned; it may be at present, it was not then.

394. (*Chairman.*) Now as to the second case, the second case was in January 1873?—Yes.

395. What was the ship's name?—"The John."

396. She was on a voyage also from South Wales to Valparaiso?—Yes, Porthcawl to Valparaiso.

397. Will you state what the nature of the coal was?—The same kind, smelting coal.

398. From the same colliery?—No, from another colliery, but it was the same character of coal.

399. Do you know from what colliery it came?— I cannot say exactly.

400. It was shipped at Porthcawl?—Yes.

401. Where did the combustion take place?—Off the Falkland Islands, when she had been 100 days out.

402. In the former case the ship had been about 60 days out?—Yes.

403. Do you remember the circumstances under which the ship was loaded: was it wet weather?— Yes.

404. Was the coal received on board in the usual way?—Yes.

405. Was it as small coal as the other?—It was about the same character of coal; it was smelting coal.

406. How was the "John" ventilated?—In the same way.

407. Was she about the same tonnage as the "Morning Glory"?—She would have about 580 tons on board.

408. She was rather a smaller ship than the other? —Yes.

409. Was the fire suspected some time before it broke out?—Yes, some days before. They felt the heat in the cabin some time before.

410. Do you remember what they did when they first found it out?—They threw water down.

411. Was the ship burned?—Yes, they ran on shore on the Falkland Islands to save their lives.

412. Both became total losses?—Both became total losses.

413. Was there any suspicion of the presence of much iron pyrites in the coal?—Not to my knowledge.

414. In fact the two cases were on all fours?—Yes, just about the same.

415. (*Mr. Ferguson.*) Was she a wooden vessel likewise?—Yes.

416. (*Dr. Percy.*) In 1873 the price of coal was very high, was it not?—Yes, in 1873 and 1874.

417. I suppose it is probable under those conditions that an inferior kind of coal might be supplied?—I cannot say that.

418. There might have been rather more slack than usual?—I cannot say.

419. (*Mr. Fenwick.*) You say she was fitted as a copper ore ship?—Yes, with a platform and trunk, so that when the ship was coal-laden the platform would be down, but the trunk would be taken away, leaving the uprights.

420. What space was there between the platform and the bottom?—Four feet.

421. (*Chairman.*) Have you any suggestion to make to the Commissioners on the subject referred to them, which is, what precautions should be taken to prevent the spontaneous combustion or explosion of coal, or what special steps should be taken when the existence of combustion is suspected?—In the case of smelting coals or gas coals much more difficulty arises than in the case of steam coal, but I think as regards small vessels on short voyages it would be a sufficient precaution if for a little time after the vessel was loaded, the hatches were kept off every fine day during the voyage; but in a larger vessel, where there is a greater quantity of coal, and where the voyage is longer, I think she ought to be properly ventilated. I think those vessels which are not fitted with trunks ought to have ventilators on each side of the keelson, and a ventilator up each hatchway and one besides those between the hatchways. A large vessel ought to have ventilators within a foot of the deck at least, and I think she ought to have screw ventilators some height above the decks, so that the water would not go down.

422. Those are all the precautions that you think would be necessary?—My own idea is that the heating of the coal is attributable to a great extent, to the coals being shipped fresh from the colliery, they come direct out of the mine into the vessel and as they fall into the vessel they break and the gas generates about the vessel. But you could not very well remedy that, the only remedy would be to apply precautions on board the vessel at sea. In former years the coals used to be allowed to lie in heaps some little time and the gas got away before they were shipped; but now they come, one may say, red-hot out of the mine.

423. Do you think they will continue to come, as you describe it, red-hot out of the mine, even when the price falls as it is falling?—Yes; because they will not work them in advance of the demand for them.

424. Is it your opinion that the intervention of Government, by means of a special inspection of coal-laden ships, would be of any advantage?—I think if there was a general law laid down providing for certain precautions, it would be acceptable to shipowners and it would be observed by them. All the owners that I have come near are anxious to save their vessels and they would be very glad to ventilate them. In fact, most of the merchants have the provision inserted in their charters, that the ship is to be ventilated.

425. You think if the law provided that certain precautions should be taken, the anxiety on the part of owners to save their own property would be quite sufficient an inducement for those precautions to be taken, and it would not be necessary to have an army of inspectors to inspect coal-laden ships?—Not at all.

426. What would you prescribe by law as to the ventilation of coal-laden ships?—The difficulty would be this, that each different vessel might require to a certain extent a different kind of ventilation. For instance in an iron vessel you might have permanent ventilators in different parts of the vessel, such as the stanchions and the timber heads might all be ventilated; but in a wooden vessel you would have to depend on screw ventilators on deck.

427. Could you formulate those requirements in any way, so that they could be expressed in a law, or in regulations having the effect of law?—I think it would be quite possible.

428. Do you think the Board of Trade could be empowered to make regulations?—Yes

429. How would they be enforced?—There is the difficulty; unless there were some person to see the vessels when they went away, I do not see how the regulation could be enforced.

430. You have not perhaps thought that point out? No. Before I left Newcastle I was told there was an old captain who had saved two or three vessels after a fire had taken place. He did it in this way (*producing diagram*). He had a number of wooden cones made, which he put on the top of one another as he dug down to the heated coals. He would put down one of these cones, in the inside of which there would be room for a man to work the coals, and then when he had got down to a certain depth he would put another cone on the top. He saved three vessels by that means. The cones would be 4 feet high by 4¼

Mr. C. Tully.

8 June 1875.

feet wide; there would be just room enough in them for a man to work. One man could not work in them for very long; he kept changing the men and kept working down, making a sort of shaft as it were.

431. Did he keep a stock of those on board?—Yes, he saved three vessels in that way, the "Cambria," the "Manfred," and the "Druid." They all took fire by the heating of the coals, and he saved them in that way.

432. (*Mr. Duncan.*) If those cones were only four feet square he could manufacture them out of inch and a half boards?—He must have made them on board.

433. (*Chairman.*) He did not take them with him?—No, he did not anticipate the fire.

434. (*Mr. Young.*) Did he make them after the fire began?—I cannot answer that question; he got them right down to the spot where the fire was. He told me that from the working of the cargo in the ship there was very little labour after the first one had been got down; it was just a matter of getting the first one down.

435. (*Chairman.*) What depth would the cones in that diagram represent?—About 18 feet.

436. (*Mr. Cory.*) That diagram is not intended to represent the precise number that would be required?—No.

437. (*Mr. Duncan.*) You say that for the purpose of ventilating the upper part of the vessel below the upper deck you would have screw ventilators?—Yes.

438. Have you ever seen the ventilator which is called McKinnel's ventilator, which has an up and a down shaft?—No, not to my knowledge.

439. A ventilator which has an outer and an inner jacket?—No, I have not seen it.

440. Such a ventilator as that which would constantly act would be better than your proposal?—Yes.

441. (*Mr. Ferguson.*) You have given us the particulars of two casualties which have occurred out of the whole number of coal-laden vessels which you have sent away during the time you have been a ship owner; what has been the total number of coal-laden vessels you have sent away?—Very many; we send between 400 and 500 cargoes away every year.

442. The proportion of burnt vessels to the total number of vessels you have sent away would be very small?—Very small indeed; I could not say how many years we have been shipping coal, but a great many years, and we only have had those two cases. That sort of casualty has mostly taken place of late years in the case of very large vessels bound to India, and it has taken place more with steam coals than with other coals. We have a fire-engine on board all the vessels, that is to say, one of those small engines they wash the decks with, and in case of fire they put the hose over the side of the vessel, and pump the water.

443. Is it not a steam pump?—No, a hand pump.

444. (*Dr. Percy.*) You spoke of the occurrence of spontaneous combustion; have you had any experience of explosion from gas?—No; I have known two or three instances on the Tyne, where after the gas coals had been loaded and the hatches had been put down, immediately the vessel blew up altogether, that is to say within two or three hours afterwards. In those cases the vessel had not begun her voyage, but the hatches had been put down, and the coals being full of gas, they caused an explosion.

445. Did I rightly understand you to express an opinion that steam coals were more liable to fire than other coal?—No, smelting coals are more liable to fire, but of late years the steam coals have been shipped in large vessels that they have taken fire more than the ordinary smelting coals which have been shipped in smaller vessels.

446. What particular kind of steam coal do you refer to, Welsh coal or north country coal?—Some of the north country; my experience is more in connection with the north country coal.

447. Do you know of any case of spontaneous combustion in the case of Welsh steam coals?—I should think there have been such cases; those vessels to which I allude carry between 2,000 and 3,000 tons, it is a great quantity of coal to be put in one vessel.

448. (*Mr. Fenwick.*) Do you ventilate all your vessels?—Yes, that is to say all vessels going any distance, not if they are only going to Spain or Portugal.

449. Your impression is that ventilation is very important?—For a long voyage.

450. (*Mr. Cory.*) I presume with respect to ships employed in coasting voyages it would be quite unnecessary to ventilate them?—Yes, they are only three or four days out.

451. Are you aware of any fire having taken place in those cases?—I never heard of one. I have heard of them being blown up after being loaded. Being small vessels there is not the same quantity of gas generated in the vessel.

452. (*Mr. Duncan.*) You have had great experience in shipping coals; you are a coal exporter?—Yes.

453. What is your experience with reference to the coals that are shipped in the present day, as compared with the coals which used to be shipped in former years, say ten or a dozen years ago, are they as well screened now, and in as good order for shipment as they used to be?—Better, I think. The screens are better now than ever they were, and the mode of shipment is better. In former years they lowered the coals down in wagons, and they knocked out the end of the wagon when perhaps it was 10 feet above the vessel. Of course all the coals went down, breaking as they went. Now they have spouts. The coals shipped by spouts certainly do break in large vessels, on account of the depth of the hold, but the spout itself comes down close to the hatchway of the vessel. They do not load the coal by wagons as they used to do.

454. Where are those coals screened?—At the pit before they come down to the spout.

455. How are they screened?—They have a large metal screen, and as the coals come out of the pit they are put through the screen, and the small coal goes one way and the large goes another.

456. Is it not the case that the coals come up in the truck from underground, and are then run on a railway to the edge of the staging to the screen upon which they are tipped?—Yes.

457. And the coal when screened goes direct into the wagons that go to the ship?—There are two wagons; one of the wagons receives the small coal, and the other wagon receives the large coal.

458. The one that receives the large coal stands at the end of the screen, and the one that receives the small coal stands under the screen?—Yes.

459. If there is a considerable slope do not you think it quite possible that some of the unscreened coal as it runs down may get mixed with the screened coal?—No.

460. In the rush down from the top of that screen to the bottom of it, might not a good deal of dust get into the large coal?—No, not much.

461. You are prepared to say that according to your experience coals are as well screened now as formerly?—Double screened coals which are the best steam coals are free from small when they are sent from the pit, of course they break afterwards.

462. Have you any reason to believe that on account of the high price that has been paid for coal, there may have been a temptation to the coal owners to ship a lower class of coal?—They could not do so, because their pit only produces a certain class of coal. For instance, north of the Tyne we have our steam coal pits, and those pits only produced the steam coals; we have other pits that produce gas coals.

463. In some of those pits many different seams, in the same pit.

464. Would you consider house coals as safe to ship as steam coals?—Quite as safe.

465. Would they be as a rule as well screened?—I think so.

Mr. C. Tully.

8 June 1875.

466. Supposing when a vessel was being loaded with steam coals they had not the necessary quantity of steam coals, and they made up the quantity with ten or a dozen tons of house coals, would that have an injurious effect upon that cargo?—No; it would not produce the steam when it got to its destination; but, so far as regards safety in carriage, I think it would be as safe. It would soon be detected that it was not steam coal, and the shipper would not get another order.

467. (*Chairman.*) Can you give the Commission the number of ships and the tonnage of the coal you have sent out?—We ship between 400 and 500 cargoes a year. I should say on the average they would be 300 to 400 tons.

468. (*Mr. Icely.*) Is it the custom to shelter the coal before shipment?—No, they could not do that; it comes down direct from the pit; if it is wet weather it receives the wet, and if it is snowy weather it receives the snow.

469. (*Mr. Young.*) I understand you to say that both those vessels were built to carry ore home; do you think the platforms and other things in ore ships tend to facilitate combustion, or to stop it?—I think so, they tend to prevent it. I think that has been proved by the very few copper ore ships that have been burnt.

470. The platforms are all made of wood?—Yes.

471. If there were combustion at all the wood would assist it?—With the platform above, and the ceiling underneath, there is always a current of air.

The witness withdrew.

Mr. James Finlay examined.

Mr. J. Finlay

472. (*Chairman.*) You have been master of a ship for some time?—Yes, from 1852.

473. And you have been carrying coal in the ships of which you have been master?—Yes, constantly.

474. I believe you have had no case of combustion since you were master of a ship?—No.

475. When you were chief mate you had a case, I believe?—I had one case, in 1851.

476. Will you describe to the Commissioners the particulars of that case?—The ship was the "Alfred" of Belfast. She was loaded in London. The coals were brought from the Tyne in colliers. She was 1,073 tons register, and we only took 1,050 tons of coal.

477. You were only half full?—About half full, a little more. The coals were shipped on owner's account, bought in the London market. I noticed the coals were small sized. I noticed they were weighed into the ship in drafts of 2 cwt. at a time by a sworn meter. She was bound for Valparaiso. We got on all right till we were off Conception, within a few days' sail of Valparaiso, when one morning, at daybreak, on opening the hatches we found a strong smell of coal gas; that was the first intimation of there being anything wrong. Soon after that smoke began to ooze up through the coals. We dug a large pit in the coals where the smoke was coming up the most, as deep down as we could, as long as the men could stand, for the smell of the gas made them sick. We then cut a hole in the upper deck over that, and poured down water and filled the pit quite full till it overflowed. The water did not seem to penetrate the coals much, as it overflowed and ran down by the ship's side. It was all of no avail, the smoke and heat increased in the hold, fire broke out, and about 60 hours after we first discovered that there was anything wrong we were driven out of her. The ship was then like a volcano.

478. The ship was lost?—The ship was lost.

479. Was the coal steam coal?—I could not say.

480. You described it as being small coal?—I noticed that it was small-sized coal.

481. It had not been screened I suppose?—I do not know.

482. Do you know how the ship was ventilated?—There was no ventilation whatever through the coal. We kept the hatches open in fine weather. We kept them on at night, and opened them in the day.

483. She was not a regular coal-carrying ship?—No.

484. Was it the first time she had carried coals?—Yes.

485. She was an ordinary cargo ship, not fitted for carrying coal, in fact?—Yes.

486. It was a case of combustion in an unventilated ship?—Yes, that ship had no 'tween decks. I consider 'tween decks a great help to a ship in the way of ventilation.

487. Have you had much experience of coal carrying since?—Yes; I have carried 15 cargoes to the East Indies and China, some of them very large, over 1,800 tons.

488. Within the last few years?—Within the last 20 years.

489. Have those ships been generally fitted for the carrying of coal?—Yes, they were ventilated.

490. How were they ventilated?—Wooden ventilators ran fore and aft through the bulk of the coals in the lower hold; 'tween decks they were not required as there is only a limited thickness there. This is a model of the ventilators which are put through the lower hold (*producing it*).

491. Those were put horizontally?—Yes, fore and aft, on each side of the stanchions. Suppose this is the middle of the ship, on each side there is a line of these ventilators fore and aft.

492. (*Mr. Duncan.*) At the bottom?—No, in the middle. In the ships I have commanded the lower hold would be about 16 feet in depth, and the 'tween deck about 7 or 8. The ventilators ran through the centre of the lower hold.

493. (*Chairman.*) Have they all been fitted in that particular way?—In that particular way.

494. Is that plan of ventilation your own invention?—No.

495. Is it a common plan?—It is a common plan adopted in vessels loading at Birkenhead.

496. What upright ventilators had you besides?—We had one in the main hatch. We connected the two ventilators in the main hatch, and put one upright in the after part of the main hatch.

497. Was there nothing up the fore hatch?—We kept the ends of the ship clear right down to the keelson, and these fore and aft ventilators projected through both at the fore end and the after end.

498. If the hatches were down what ventilation would the ship have then?—We had always some scuttles down through the forecastle and down aft, and four cowl-headed ventilators through the poop and forecastle open all weathers.

499. All ventilating upwards?—Yes.

500. Nothing ventilating downwards?—No; except that some of the mouths of the ventilators were generally turned to the wind, and the others from it.

501. So that some would ventilate downwards, and the others upwards?—Yes, according to the wind.

502. According to your experience that method is a very satisfactory one?—Yes.

503. Have you carried coal of all kinds—north country coal and South Wales coal, bituminous coal and non-bituminous coal?—The principal coals which I have carried were North Wales coals, Brymbo coal. We shipped one cargo of Merthyr steam coal at Birkenhead.

504. Have you ever had any suspicion of heat in any coal which you have shipped?—No.

505. Do you attribute your immunity in any degree to satisfactory ventilation?—Entirely, and keeping the hatches open.

506. You say that that system is common in Birkenhead ships; do you mean that it is adopted in all ships sailing from Birkenhead?—I cannot say that it is universally adopted. I know that a good many have it.

507. Do several different owners apply the same

Mr. J. Finlay.

8 June 1875.

plan?—Yes, I believe so. The firm by whom I am employed have a great many coal-laden ships, and in those ships this plan has been invariably adopted, instructions being given to keep the hatches open.

508. (*Mr. Duncan.*) As to that cargo which you took from London, was it small coal like what you would call smithy coal?—No, it was ordinary coal.

509. Such coal as you see discharged from vessels in London for steam purposes?—Yes.

510. It did not appear to have been very well screened, but it was steam coal?—Yes.

511. It was not small coal?—No, not small coal entirely, there was some large among it.

512. The two handlings of the coals, first in the shipment on board the brig, and then on board your vessel, would have a tendency to break the coals; would not the distance which they would have to fall break them a great deal?—The depth they would have to fall in the ship's hold would be gradually decreasing, there would be a very small fall towards the end of the shipment. The coals were wheeled away from the hatchways in barrows.

513. Was she a colonial-built ship?—Yes, a St. John's built ship.

514. From the way in which she was loaded the whole weight of the coal would go down upon that which was at the bottom, and make it closer?—Yes.

515. Do not you think it would be an improvement in the case of those vessels which you say are ventilated in the way you have mentioned, if you had one shaft coming up through the quarter hatch, and another shaft coming up through the fore hatch, with which shafts the horizontal boxes which you say you placed fore and aft among the coals could communicate?—Yes, no doubt it would.

516. (*Chairman.*) That is a very cheap method of ventilation, is not it?—Very cheap.

517. What would it cost in the case of a ship carrying 1,200 tons?—The ship in which I sailed last was a ship 1,300 tons, and I reckoned that it cost about 13*l.* for the material.

518. The original cost?—Yes; the ship's carpenter made it on board as it was required, and saw the ventilators properly placed.

519. (*Mr. Ferguson.*) Do you know whether any of the other vessels which have from time to time loaded at Birkenhead, and which have adopted that plan of ventilation have taken fire?—I do not know of any; the employers for whom I sailed had at one time over a dozen ships, and they were nearly always carrying out coals to the East, and I never heard of a case of combustion in any one of them.

520. Have you heard of any casualty occurring in the case of any of the vessels which loaded at Birkenhead with the same coal, and which adopted the same method of ventilation?—No; I never heard of any casualty having occurred in the case of any one of those vessels in which that plan of ventilation had been adopted.

521. (*Dr. Percy.*) How long has this system of ventilation been in operation?—For over 20 years to my knowledge.

522. (*Mr. Abel.*) Are you in the habit of examining the cargo periodically, or the ventilators, to ascertain whether the coal remains cool?—I was in the habit of visiting the hold each day.

523. Is that a rule laid down by you on board ship?—No, not a stringent rule, but I made it part of my duty to go over every part of the ship every day.

524. You do not keep a record of having inspected the cargo, and seen whether there is any heating?—No.

525. (*Chairman.*) Do not you mention it in the log?—No.

526. (*Mr. Abel.*) Have you ever known a case of explosion on board a coal-laden ship?—No.

527. (*Mr. Young.*) Most of the cargoes you have carried have been from Birkenhead?—Yes.

528. You are in the employment of a Liverpool firm, I believe?—I was till I left off going to sea in 1872.

529. What is the name of the firm?—Messrs. J. and T. Sinclair of Belfast and Messrs. W. and P. Sinclair and Co. of Liverpool. I have taken three cargoes from Sunderland.

530. (*Mr. Icely.*) What is the name of the coal you have been in the habit of carrying?—Brymbo. One cargo I took from Birkenhead was Merthyr steam coal. From Sunderland it was Londonderry and Cowpen coal.

531. You have carried all those coals which you have mentioned?—Yes.

532. And never had an accident with them?—No.

533. Are you in the habit of shipping coal in all weathers?—Yes, I have shipped coal in wet weather.

534. You have known a cargo to be wet when shipped?—A little wet.

535. Charged with moisture?—Yes.

536. Still no accident has occurred?—None whatever.

537. (*Mr. Fenwick.*) You must have met with a great many other ships which have taken coals out to India; do you know whether they have all been ventilated?—There is a great diversity of opinion about ventilation; some captains are strongly in favour of ventilation; the majority I have talked with on the subject are in favour of ventilation, others are not.

538. You do not know whether every coal-laden ship that sails for India has been ventilated?—No; the majority are in favour of ventilation, but I have met with some, a few, that do not believe in ventilation.

539. (*Mr. Cory.*) Most of those cargoes which you loaded at Sunderland, and those you shipped at Birkenhead, came direct from the colliery to the ship?—Yes, as far as I know.

540. In the case of the particular cargo which you loaded in London, they had been some time out of the colliery, no doubt?—Yes.

541. They had had a thorough airing?—Yes.

542. Nevertheless, that particular cargo was the one that took fire?—Yes. We did not think there were any particular precautions necessary as the vessel was not taking a full cargo.

543. (*Chairman.*) May I sum up your evidence as expressing this, that provided that system of ventilation was applied to which you have referred, and provided the hold is visited every day, you would feel perfectly safe in carrying coal to any part of the world?—Yes.

544. You believe that those are all the precautions that are necessary to be taken?—Yes; and keeping the hatches off night and day.

545. Whenever the weather allows?—Yes.

The witness withdrew.

Mr. J. P. Newton.

Mr. JOHN PAUL NEWTON examined.

546. (*Chairman.*) You have been for some time commanding a coal-carrying ship have you not?—I have been in several ships carrying coals.

547. For how many years?—Since 1842.

548. How long have you been a captain?—Twenty-two years.

549. Have you made many voyages every year?—Yes. I have not been carrying coals continuously, but from time to time during that time.

550. How many voyages altogether have you made with coal?—I have carried coals from England to the Baltic once or twice, once to the Mediterranean, twice or three times to the Brazils, once to Calcutta, once to Shanghai, once to Japan, and once to Aden.

551. During the 22 years that you have been making voyages as a captain, have you had more than one case of spontaneous combustion?—Only one case.

552. Will you describe to the Commission what the particulars of that case were?—The vessel which was called the "Lochee," was loaded in the Tay, off Tayport, in the month of September, 1864. The weather was very wet and there were gales of wind every day. The coals were brought off in lighters, and the lighters

Mr. J. P. Newton.

8 June 1875.

in some cases were nearly foundering alongside, so that the coals were thoroughly saturated with both rain water and salt water. The coals were filled in tubs and whipped on board ship out of the lighters.

553. They came on board very wet?—Thoroughly saturated with wet. The ship just had her registered tonnage; she was not nearly full. She had 90,000 cubic feet of spare space. Her registered tonnage was 1,500 tons, and she only had 1,500 tons of coal in her. We sailed on the 17th of September, 1864, for Calcutta. Then on the 4th of January, 1865, about three months afterwards, we discovered a little smoke from the coals. On discovering this smoke I lowered the thermometer so as to get the temperature, which I found was very high, and I considered then that if she was not burning, she would very soon begin to burn. I was then in the Bay of Bengal. I immediately bore up for Ceylon, and when I was in sight of Galle she blew her decks out from end to end. That was a thing I had never heard of before or expected. I never apprehended any danger from explosion. No one could credit the force of the explosion. The decks were literally blown out. All the men were burnt and bruised. She went into flames immediately and we all got out of her as quickly as we could.

554. To what do you attribute that casuality?—I have not the least doubt that it was from the coals having been shipped wet. On the voyage before that, we had in the same ship 2,000 tons, which we shipped in London, and at that time she went perfectly safe. They were loaded then from small vessels, and the coal came from the north of England.

555. What coal was it in this case?—It was coal from the Town Hill Colliery in Fifeshire.

556. What coal is that?—Steam coal.

557. Since that casualty occurred I believe you have carried no coal?—No.

558. (*Mr. Duncan.*) I suppose you have known cases of this Town Hill coal taking fire since that time?—Yes, and before.

559. You have no reason to suppose that those cargoes were loaded in bad weather, or that the coals were saturated with wet?—I was in Dundee when the "Robert Gilroy" was loaded. She was loaded before the "Lochee." The coals which she shipped were very similar to those shipped by the "Lochee."

560. Were they loaded in the roads by lighters?—She took the greater part in in the dock, and finished loading in the river.

561. Was it very wet weather? — It was wet weather. She had a full cargo.

562. Those coals were brought from Fifeshire?—From the Town Hill colliery, the same colliery.

563. You have heard of other cases of this Town Hill coal burning where there was no reason to believe that the coal was saturated with moisture?—Yes; I have heard of several where the vessel has been destroyed having shipped the same coals, but I never took any interest in it till I was burnt out myself.

564. Have you any knowledge whether in the case of any of those ships that were burnt the coals were shipped dry? — In 1847 I went to Aden in the "Alexander," belonging to Dundee, and we took 1,000 tons of coal off Tay port in the month of May in dry weather, and no casualty happened in that case.

565. Were they Town Hill coals?—They were shipped at Tay port. I could not tell which colliery they came from. Those coals in 1847 went perfectly safe to Aden.

566. Do you remember what coal a ship which went out not long ago belonging to Messrs. Gilmore, Rankin, and Strahan was loaded with?—I could not say.

567. (*Mr. Ferguson.*) Previous to the explosion in your vessel how long had the hatches been on?—The hatches were off every day during the voyage. They were never battened down till the ship took fire. We never had occasion to close the hatches on account of sea. We merely put them on to keep out the rain and spray, covered with a tarpaulin, and tacked down in windy weather to prevent it being blown off, but they were never battened down.

568. You had them off nearly every day?—The hatches were lifted off the first thing every morning.

569. Were they off at the time of the explosion?—They were battened down then; that was to let the fire smoulder out, to keep it from spreading.

570. What mode of ventilation did you adopt?—There were several ventilators 12 feet apart, fore and aft, and in the main hatchway we had a ventilator at each corner.

571. Did those ventilators come up above the hatchway, or were they beneath the surface of the hatchway covers when the hatchway covers were on?—They were vertical ventilators made of wood.

572. Did they come up through the hatchway?—Only up to within 2 or 3 feet of the main deck.

573. Had the ship a permanent ventilator?—Yes. The ship was very well ventilated in that way, but I sealed her up tight when there was an indication of heating. This ventilation in the main hatch came up just under the hatch.

574. Was she an iron ship?—No, a wooden ship.

575. (*Mr. Abel.*) How long previous to the explosion had you any indication that there was anything wrong?—It was only 24 hours before she exploded that we had any knowledge of what was going on.

576. Then you found considerable indications of fire?—No, there were no indications of fire whatever till the morning before.

577. Do you remember any other case in which you noticed heating in a cargo of coal?—No. I never saw any heating in a coal cargo before in my experience.

578. (*Mr. Icely.*) You said just now that you lowered the thermometer into the hold when you discovered that the cargo was becoming heated. Had you been in the habit previously of trying the temperature of the cargo?—No; I never tried the temperature before.

579. It was only when you felt that there was heat that you put down the thermometer?—When I saw that the coals had really taken fire, I wanted to ascertain where the fire was. There was no doubt that it was in the main hatch.

The witness withdrew.

Adjourned to Tuesday next at 12 oclock.

Tuesday, June 15th, 1875.

PRESENT:

THE RIGHT HONOURABLE HUGH C. E. CHILDERS, M.P., IN THE CHAIR.

SIR GEORGE ELLIOT, Bart., M.P.
HENRY HUSSEY VIVIAN, Esq., M.P.
FREDERICK AUGUSTUS ABEL, Esq., F.R.S.
RICHARD CORY, Esq.
GEORGE DUNCAN, Esq.
JOHN FENWICK, Esq.
JOHN FERGUSON, Esq.
CHARLES ICELY, Esq.,
JOHN PERCY, Esq., M.D., F.R.S.
WILLIAM YOUNG, Esq.

J. M. CARMICHAEL, Esq., Secretary.

MR. JAMES WRIGHT examined.

Mr. J. Wright.

15 June 1875.

580. (*Chairman.*) You are engineer-in-chief to the Admiralty?—I am.

581. I believe you can give us some information about the cases of spontaneous combustion or explosion of coal which have occurred in Her Majesty's ships for some years past?—The papers generally

Mr. J. Wright.

15 June 1875.

pass through my hands, and I have looked up the records during the last seven years. So far as I can ascertain with any degree of exactness there have only been about five cases of spontaneous combustion, and two cases of explosion in men-of-war which were considered of sufficient importance to be reported during those seven years.

582. That is quite irrespective of ships chartered by the Admiralty to carry coal ?—Quite irrespective of those.

583. Can you give the Commission the particulars of some or all of those cases ?—Beginning in 1868 the first is the case of the "Euphrates" Indian troop ship. When nearing Bombay, shortly before midnight smoke was observed issuing from the starboard bunker. Fortunately there were only about 20 tons of coal in that part of the bunker. The fire was extinguished without any serious results. It was supposed to have been caused by the fact that some of the Spence's cement with which the boiler was covered had fallen off and an undue amount of heat had been communicated from the back of the boilers to the coal in the boxes. The kind of coal is not reported, but I believe it was Welsh coal.

584. That in the opinion of the Department was not a case of spontaneous combustion ?—Not a case of spontaneous combustion.

585. But of communicated heat ?—Yes.

586. What was the next case of which you have any particulars ?—The next case was that of the "Megæra." In February 1870, on her passage from England to Ascension, the temperature in the wing bunkers was discovered to be rising from 130° to 145°, and it was considered necessary to clear part of the bunkers. They did so, and the coal was found to be considerably heated, but no damage of any importance was done. The coal in that case was the Hirwain Aberdare.

587. What was the view of the Department as to the cause of the casualty in that case ?—The bunkers were reported to be well ventilated ; the usual precautions had been taken to prevent overheating. It was supposed that heat had been communicated in that case to the coal, but that was proved not to be the case* as the boilers were well covered, and no steam pipes went through the boxes. It was one of those difficult cases in which you could not give any clear reason for the heating of the coal. The Hirwain Aberdare is supposed to be a hard coal of the nature of anthracite, rather more so than most of the other coals. No satisfactory cause, I think, was ever given.

588. Was there an inquiry ?—Only the reports of the different officers upon the subject ; it was inquired into as well as it could be, but nothing satisfactory came of it as far as I could ascertain.

589. You were then at the Admiralty ?—Yes.

590. You could not arrive at any satisfactory conclusion ?—No.

591. What was the next case ?—The next case was the "Malabar" Indian troop ship. In February 1872, on her passage to Bombay, a strong smell of sulphur was observed by the men working at the boilers, on both sides at the same time. The bunkers were immediately cleared, and all ventilation stopped. The doors in the after end of the stokehold were opened, and the coal taken out as fast as possible. Much of it was found to be smouldering and heated, and only requiring a little air to burst into flame. It was necessary to flood the boxes entirely to put out the fire. The coal had been received from under cover at Malta only 16 days before, and was perfectly dry and apparently well mixed. It consisted of one half Cowpen Hartley received at Malta in April 1871, and one half Fothergills Aberdare received at Malta in September 1871. The test-tubes did not show any sign of the heat before the discovery, and afterwards they never showed more than 110°, which is very little above the usual temperature in the Red Sea.

592. What conclusion did you come to in that case ?—No decided conclusion was come to in that case either.

593. The coal was put on board perfectly dry ?—The coal was put on board perfectly dry, in good condition, and well mixed.

594. There was no reason to believe that the casualty arose from any external cause ?—Not in that case.

595. (*Mr. Vivian.*) That was the coal in the bunkers ?—Yes.

596. (*Chairman.*) What is the next case ?—The next case was that of the "Glasgow" on the East Indian Station. On the 22nd of June 1872 it was discovered that there was a heating of the coals in the starboard aft coal bunker. It was found that the greatest heat was about 6 feet down, and about 4 feet from the side athwart ships. The coal there was found to be at a temperature of about 135°. The coal was received on board perfectly dry, and in fine weather. The coal had been received at Aden, Bombay, and Trincomalee. It had been received on board in small quantities at those places. It consisted of Davis's Merthyr, Davidson's West Hartley, Tyne fine Merthyr, Cowpen Hartley. The greater part of it was Welsh coal ; it would probably be three-fourths Welsh and one-fourth of it North-country. There was no damage done in that case, and no clear reason was assigned for the heating of the coal.

597. What was the next case ?—The next case was the "Rattlesnake" on the coast of Africa. On the 20th of February 1872 smoke was discovered to be issuing from the bunkers at the back of the starboard boilers. On removing about 20 tons some discoloured coal was found. Precautions were taken to stow the coals quite dry. The coal was observed to contain a large quantity of sulphur and iron pyrites ; that was the report of the officer. I suppose it would be sulphide of iron.

598. In that case did you form any judgment as to the cause of the heating of the coals ?—No.

599. What coal was it in that case ?—It was entirely Cowpen Hartley.

600. In the two other cases, the "Malabar" and the "Glasgow," there was also some Cowpen Hartley on board ?—In small quantities.

601. (*Chairman.*) Will you go to the next case ?—The next case was the "Daphne," on October 11th, 1874. She was lying at Trincomalee. One lid of the port aft bunker and one lid of the starboard aft bunkers were blown off, and a flash of flame was observed. Smoke was then seen ascending. In shovelling out the coal a stoker came across a small portion of burning coal. The pumps were then used, and the fire was extinguished. The temperature of the bunkers before the occurrence, close to the seat of the fire, was not beyond the usual average. Starboard the temperature was 92° and port it was 95°. The main steam pipe passes through the port bunkers so that its temperature is rather higher than starboard when the ship is under steam. The coal was two thirds Nixon's Navigation and one third Davison's West Hartley. It was shipped at Aden in a perfectly dry state. It also appeared dry on the 11th of October. It afterwards transpired that the bunker lids on those coal boxes had not been removed for some time previous to the fire, contrary to regulations. It was supposed at first that the casualty was caused by an explosion of gas which had communicated the fire to the coal.

602. Was there any special inquiry in that case ?—There was an inquiry by the Commander-in-Chief.

603. Do you know by whom it was conducted ?—The Commander-in-Chief made the inquiry personally, I think.

604. What was his opinion ?—His opinion was that it was through not ventilating the coal boxes sufficiently.

605. Did you concur in that ?—So far as we could see there did not appear to be any other reason assignable for it. Those are the cases of coal taking fire. The only two cases resulting from explosion of gas occurred in the "Devastation" and the "Minotaur."

---

* *See* Admiralty Papers, page 62, which confirm this statement, and show that Mr. McCulloch in his replies, No. 729 and 730, was mistaken.

Mr. J. Wright.

15 June 1875.

In the "Devastation" in June 1874, the ship's cook's assistant very early in the morning entered the bunkers with a naked light and an explosion of gas took place.

606. Was any mischief done?—There was no mischief done except that the man was burnt somewhat about the face and neck; the bunkers lid had been removed two days before, so that the gas must have been generated during the interval.

607. Was anything done to the coal afterwards?—No, the coal was all examined. No increase of temperature was found to have been caused, and there was no appearance of any heating in the coal.

608. What description of coal was that?—Welsh. $\frac{2}{3}$ Fothergill's Aberdare and Insole's Merthyr, I think, and $\frac{1}{3}$ Cowpen Hartley.

609. What was the date at which the coal was received, and how long before that date had it come away from the colliery?—The coal had been shipped at Portland six days before. The bunkers was nearly full; there was no indication of heat or damp; the temperature was 66°, and the explosion was confined to the neighbourhood of the aperture.

610. The "Devastation" was one of the Channel fleet?—She was lying at Portsmouth at the time.

611. The "Devastation," while in the Channel fleet, received nothing but Welsh coal?—It was mostly Welsh, but mixed as before mentioned in the bunker where the explosion occurred.

612. The other case of explosion was the case of the "Minotaur?"—Yes, in June 1869. There then was a slight explosion of gas in the starboard aft bunker opening into the shell compartment. On a light being lowered into the bunker for the purpose of examination it was blown out by the rush of gas, and there was a slight explosion, but no harm done—nobody was injured.

613. Was the coal turned over afterwards?—The coal was examined and it was found that there was no heating; the temperature in the forward bunker was 71°, and in the aft bunkers 68°.

614. What coal was that?—A mixture of several kinds of Welsh and north country received on board at various times during the previous nine months. The last supply was received at Lisbon in May 1869, it was on the top of the other coal, and consisted of Dowlan's Merthyr, Ocean Merthyr, Powell's Duffryn, Hastings Hartley, and Cowpen Hartley; exact proportions not recorded.

615. Those are all the causes of spontaneous combustion or explosion which have occurred in the navy for some time past?—They are all the cases that appear to have been considered worth reporting to the Admiralty within the last seven years.

616. Can you tell the Commission what precautions are taken in the navy to guard against over heating and to detect any rise of temperature?—There is an old standing order that the wood work of all coal boxes is to be lined with sheet iron and the Captains are to see that the coals are never shipped wet. They are to see that they are kept as dry as possible on board, and when a fresh supply is received they are to cause as much of the old coal as possible to be trimmed forward so that it may be used first, and they are to cause the temperature of the coal to be taken through the temperature tubes every watch, and recorded. In all large ships, at least, the coal boxes are placed from 16 to 18 inches from the boilers, and means are taken to create a current of air between the coal boxes and the boilers. The boilers are covered with four thicknesses of boiler felt to prevent radiation of heat. There is a standing order also that the coal boxes shall be ventilated by the bunker lids being removed occasionally. And lately, about a year ago, a general order was issued that in all ships some means of ventilation should be provided for carrying off any gas that might be generated in the coal boxes. The general plan is to lead some light iron pipes from the upper part of the coal boxes to the nearest funnel casing.

617. Have you noticed of late years, say within the last two of three years since the great rise in the price of coal, any increase in the number of cases of spontaneous combustion?—I think not. Of late years there has been no difference. There were rather more cases between 1871 and 1873 than we have had the last two years.

618. To what do you attribute that?—I cannot give any reason for it.

619. At any rate in 1873 and 1874, when, undoubtedly the number of casualties in coal-carrying ships was much greater, there was no corresponding increase in the number of casualties in the navy?—No.

620. (*Mr. Icely.*) There was a case of spontaneous combustion of coal in a store at Jamaica some years ago. Have you the particulars of that case?—That was in September 1872. The coal was stored in a brick or stone-built building, I cannot say which, and it was roofed with corrugated zinc. The coal was Cowpen Hartley, and had been landed in April 1872. The temperature under the store was generally about 97°. The coal was discovered to be hot, and they removed about 240 tons. It was reported by the officer there that the coal appeared to contain a considerable quantity of sulphur and iron. There was no cause assigned for the heating further than that. There was no serious damage done. The coal was slightly charred and injured, but there was no serious damage.

621. Are there any means taken to ascertain the temperature in the Government stores from time to time?—I do not know that any special means are taken to ascertain the temperature in stores on shore; but a system of ventilation is carried out by louvres over the top in some cases, and in other cases by side louvres all along; but as regards the taking of the temperature, I do not think there are any distinct orders upon the subject.

622. Was there any evidence as to how the fire, or the heating of the coal was first discovered in the store at Jamaica?—That is not stated in the report. The report simply says that the coal was discovered to be hot.

623. Do you attribute the immunity which the vessels in the navy appear to enjoy from this tendency to spontaneous combustion of coal to the fact of the temperature being regularly taken, and to those orders of the Admiralty to which you have referred being carried out?—I should think that would be one great reason for it. By reason of the discipline on board a man-of-war, and by the temperature being regularly taken in that way, a fire is prevented from getting ahead to any extent before it is discovered. It is rather strange that in two of the cases which I have mentioned, the thermometer on being lowered in the temperature tubes did not show any unusual rise. The fire or heating seemed to be confined to a very small space. It was first discovered from the smoke or sulphurous fumes coming up the boxes, not from the indications of the thermometer.

624. Have you in any of the cases any information about any rise of temperature having taken place; for instance, is there any statement that the thermometer was lowered at a certain time and gave you a certain number of degrees, and that it was lowered at another period, an hour or so after, and that it showed an increase in the temperature during that period, so as to indicate whether the heating took place rapidly or not?—No, I do not think that in any of these reports that has been recorded, for in most cases as soon as they discovered that the temperature was high they took means immediately to get at the seat of the heat, so that they did not wait to take the temperature subsequently. In all these cases I think they did not wait to record the gradual increase of the temperature.

624*a*. At present those tubes are plain. Do you think if they were perforated they would show indications of heating in the coal more readily?—They would show those indications more readily no doubt, because there would then possibly be a current towards the tube. However, I believe it is a question with some people whether it is right to ventilate coal-boxes much or not.

Mr. J. Wright.

15 June 1875.

625. Are you in favour of the ventilation of coal-boxes?—We are in favour of the ventilation of coal-boxes, so much so, that an order has been given to ventilate coal-boxes in ships of any kind, by means of these tubes leading to the funnel casings.

626. Those are outlets, but are inlets provided, or recommended?—No inlets, except what you get by removing the bunker lids, and opening the trimming doors.

627. Then would the air pass through the body of the coal?—Yes. Then when the coal was taken on board ship on most occasions the trimming doors would be open, which would give ventilation from below. The shoots in front of the trimming doors are generally free from coal, so that generally there would be a current there whenever the bunker lids or doors were open.

628. That is usually the case on board ship?—Yes.

629. An inlet is provided by that means?—Yes.

630. The exit would be through the funnel casing, where an active circulation would be kept up from the heat maintained there?—Yes.

631. (*Mr. Fenwick.*) In all those cases which you have given us, the coal appears to have been mixed coal?—It was mixed coal in most of the cases, but Welsh in the "Euphrates" and "Megæra," and north country in the "Rattlesnake." The report in that case only refers to Cowpen Hartley received at Sierra Leone.

632. It was only Cowpen Hartley in the "Rattlesnake"?—Yes, so I infer from the report.

633. Do the Admiralty take such coal as the market produces, or is the Admiralty in the habit of sending particular descriptions of coal direct to the particular ports?—I am not very well acquainted with the way in which the contracts are made at present; but I understand that Mr. Rowsell, the director of contracts, has been requested to give evidence, and he will be better able to tell you all those particulars than I am. I think the Admiralty contract, in most cases, direct with the mine owner to supply certain quantities of coal for certain stations; and the Admiralty are not at the risk of shipping them, they only receive the coals as they are sent over the ship's side, the coal owner, or the shipowner, taking all the risk; the Admiralty simply receive the coals at the stores. They order a cargo of Cowpen Hartley, or a cargo of Davisons, or a cargo of Welsh coal to be delivered at certain depôts by certain times.

634. (*Mr. Vivian.*) You have given us five cases of spontaneous combustion, namely, the "Megæra," the "Malabar," the "Glasgow," the "Rattlesnake," and the "Daphne"—Cowpen Hartley formed a portion of the cargo in four out of five of those cases—have you investigated the character of the Cowpen Hartley coal at all?—No, I have not. Samples of coal are generally tested in the coal testing boilers in the dockyard, and, speaking from experiments that were made with it, I think as a steam producing coal it is about the best of the Hartley coals.

635. In view of the fact that in four out of the five cases Cowpen Hartley formed a portion of the cargo, you have not thought it necessary to examine it so as to see whether it contained much iron pyrites or not?—No.

636. In two cases it was reported to contain iron pyrites?—That was the statement in the report.

637. (*Mr. Duncan.*) As it is not customary to have in merchants' ships which carry coals these tubes for testing the temperature, perhaps you will be good enough to describe what those tubes are?—They are simply iron tubes fitted in the deck above the coal bunkers, 3 inches in diameter, having a moveable lid, and the tubes are long enough to reach to within about 2 feet of the bottom of the coal bunkers. You take off the lid and lower the thermometer by a string and leave it till you get the correct temperature of the region around. They are fitted at a distance of about 8 feet apart.

638. They have no holes perforated in them?—They have no holes perforated in them.

639. Unless the lower end was left open, they would be apt to get the small coal in them?—Yes; and if perforated round the sides the small coal would get through.

640. Those tubes come up through the deck?—Yes, so that you can lower the thermometer down them.

641. Have you any impression that the mixing of the coals is an injury, that is to say, the combining of different coals?—No, I have no opinion upon that subject. I have not seen anything to call particular attention to it.

642. Some ship owners object to carry mixed coals having the impression that the mixing of coals is calculated to cause spontaneous ignition?—There is at present a standing order at the Admiralty that mixed coals should be used in the navy in proportion of two-thirds Welsh and one-third north country on most of the stations, and that the coals should be mixed on board, that two bags of Welsh and one of north country shall be put in the bunker alternately.

643. The fair inference from that is, that the Admiralty have no idea that mixing has any effect at all in causing spontaneous combustion?—Quite so.

644. (*Mr. Ferguson.*) Were those coal boxes in which the coals took fire nearest to the boilers?—At the back of the boilers, near the boilers, there was a space of about 16 inches in each case between the boilers and the coal box.

645. Was there a fire in the boiler in all the cases?—There was not in the "Devastation," "Minotaur," or "Daphne," I think.

646. It is not usual in merchant vessels to put the bunkers so far away back from the boilers. Six inches is about the distance in the case of old low-pressure boilers, but in the case of high-pressure boilers the distance apart is greater?—In the navy we keep them about the distance apart that I have mentioned, it is partly with the object of getting round the boilers to do any repairs, that distance gives sufficient space for a man to get between the coal box and the boilers. In some small vessels in the navy where the quantity of coal carried is necessarily small and the coal boxes are of small cubical capacity, we have been obliged to put them within about 6 inches of the boilers; in those cases the bulk of the coal is not large, and with the temperature tubes fitted we have had no reason to believe that there was any risk in putting the coal boxes so close to the boilers as 6 inches.

647. From the fact that the coals which took fire were so near the boiler, you would infer that the heat of the boilers affected them would you not?—In some cases the temperature tubes did not show any increase of heat. A little would be due to proximity to the boiler.

648. Are you aware whether, in merchant vessels, coals have become heated too near the boilers?—No, I am not acquainted with any such cases.

649. You said that you thought the navy was more free from cases of spontaneous combustion than merchant vessels?—I think so from the fact of precautions being taken to guard against danger and from the better discipline on board men of war.

650. Do you think the distance of the coal boxes from the boilers would have any share in it?—It would have something to do with it, no doubt.

651. (*Dr. Percy.*) You spoke of one case in which it was believed that fire had been communicated to the coal on account of the removal of the cement of the boiler. What temperature do you think would be communicated to the coal under these conditions?—I could hardly say; the temperature of the boiler itself would be between 260° and 270°, then there would be a space of 16 inches between the back of the boiler and the coal box, and the seat of the fire was about 4 feet in.

652. It was not on the outside that heat would be greatest?—No, but a little way in.

653. Is it the impression at the Admiralty that all coal when wet is more likely to fire than when dry?—That is the strong impression at the Admiralty.

Mr. J. Wright.

15 June 1875

654. Can you adduce any facts in justification of that conclusion ?—The only case I know of late years is a case of heating of coal that took place about a year ago in the Bermuda coal store.

655. Do you know whether that coal happened to contain much iron pyrites ?—No, the report was that it was small coal taken into store when the atmosphere was moist.

656. No reference was made to the point of its containing iron pyrites ?—No, I think not.

657. Is any really searching examination ever made at the Admiralty with a view of ascertaining the amount of iron pyrites in the coal which they consume, or the manner in which that iron pyrites is diffused through the coal, whether uniformly or in lumps ?—I do not know of any such inquiry having been made.

658. In one case to which you referred you said that the fire was very local in that case. Was any examination made with a view to ascertain whether that part of the coal in which the firing took place contained more than the usual amount of iron pyrites ?—That I think was the case of the "Daphne." In that case the report contained no statement that the coal appeared to contain more than the usual amount of iron pyrites.

659. No examination upon that point was made ?—No special examination was made.

660. (*Mr. Abel.*) According to the regulations, the operation of mixing the coal is to be carried on during the loading of the coal on board ship ?—That is so.

661. The different sorts of coal are shot into the bunkers alternately. A load of one coal is first shot in, and then one load of another coal ?—Yes.

662. Has any note been taken as regards the mechanical condition of the coal in the bunkers in those cases of spontaneous combustion ?—I think not.

663. No record exists as to whether the cargo appeared to be composed of small coal to a greater extent on some occasions than others ?—The only case in which any reference was made to the smallness of the coal was that of the coal store in Bermuda. There the report mentioned that the coal was very small, and that it lay close together ; and it was also stated that it was taken in when the atmosphere was moist.

664. (*Mr. Young.*) You have told us how the Jamaica store was built, do you know whether other stores elsewhere are of a similar description ?—Some of them are built of brick, and others are built of iron.

665. Are they always covered ?—In all cases, I think, they are covered I think all the foreign ones are covered.

666. What depth of coal is generally stored ?—Various depths, from 5 or 6 feet to 12 feet.

667. The coal would not be so deep as in the hold of a large ship ?—I think not. In some cases the coals are stored in building with brick walls and arches, and those would be from 10 to 12 feet deep ; on the top of the arches there would be *louvres*, those arches would be about 10 feet wide and perhaps 12 feet deep running in long bays.

668. So that there would be a thorough draught ?—There would be a good draught. In the coal store in Gibraltar, for instance, the back of the store is part of the rock, then there is an iron roof, and the sides are covered a certain way up, then perhaps there would be 4 or 5 feet comparatively open all round at the upper part of the sides.

669. You know of no case of combustion of coal in a store on shore, except the case at Jamaica ?—I think there was a case at Woolwich about ten years ago, but I have no particulars of that case.

670. (*Chairman.*) Experiments with regard to mixing coal for the use of the navy have been going on for the last 12 or 15 years, more or less, have they not ?—Yes.

671. Was one of the points kept in view in those experiments the liability of coal to fire ?—No, that matter did not arise in the inquiry so far as I know.

672. You said that there was some difference of opinion whether ventilation promoted or prevented spontaneous combustion ?—That is what I gather from people whom I heard discussing the question. Some are of opinion that it is not desirable to have much ventilation, the general opinion, however, is, I think, that it is desirable to have ventilation.

673. The view of the professional officers at the Admiralty is that it is desirable to have ventilation ?—That it is desirable to have ventilation in the coal boxes on board ship.

674. Would you apply *à priori* the same to merchant ships carrying cargoes of coal ?—I think so.

675. So far as the experience derived from what has taken place in the carriage of coal in bunkers in ships in the navy goes you think it points to the desirability of thorough ventilation rather than of no ventilation ?—I think so.

676. But as to coal-carrying ships you have no personal experience ?—I have no personal experience with regard to coal-carrying ships.

677. Can you give us any idea of the quantity of coal that is carried in the bunkers of a man-of war ?—It varies from perhaps 20 tons to 300 tons, according to circumstances. In large iron vessels the coal bunkers are really water-tight compartments, local conditions regulate the quantity of coal carried in the different compartments. In some cases 200 tons would be carried in one compartment, in others 40, or 50.

678. (*Mr. Duncan.*) In a vessel like the "Euphrates," the compartments would carry more than 1,200 tons, would they not ?—There are a great many compartments in the "Euphrates" ; she would carry 1,200 tons altogether. In the after coal reserves she would carry perhaps 300 tons ; then there would be 100 tons an each side of the engines ; then there would be perhaps 200 tons on each side of the boilers, and then in another reserve, perhaps, she would carry 300 tons.

679. (*Chairman.*) About 300 tons would be the outside carrying capacity of any one of the compartments ?—So far as I recollect at present that would be the outside capacity of any one of the compartments.

680. (*Mr. Vivian.*) In regard to the Bermuda store in which you stated the coals got heated about a year ago, what quantity of coal was in the store ?—I cannot say ; the report does not state the quantity.

681. What description of coal was it ?—Baltimore coal. American coal. It is a small coal, something like our Welsh coal. It was used on the North-American station for mixing with Nova Scotian Pictou coal. Nova Scotian Pictou coal is of a bituminous nature, and it was supposed to burn better with a mixture of this Baltimore coal, but since that casualty orders have been given to discontinue the use of Baltimore coal.

682. (*Chairman.*) You call it Baltimore coal ; that is to say it was shipped at Baltimore ?—Yes.

683. It was a Pennsylvanian coal, was it not ?—I believe so, and shipped at Baltimore.

684. (*Mr. Vivian.*) You have given us seven instances in which casualties have occurred in men of war. During the period that those casualties occurred, how many of Her Majesty's ships were in commission ?—The number of steamships in commission would be 170 on the average during that time.

685. The number of years in which those casualities occurred was about seven ?—Yes, the casualties would be about six-tenths per cent. per annum.

686. Rather more than half per cent. per annum ?—Yes.

687. (*Mr. Icely.*) The seven cases include spontaneous combustions and explosions ?—Yes, about that.

688. In the explosions little harm was done ?—Very little ; in fact there was no material damage done in any case.

689. (*Chairman.*) If you excluded the explosions, it would be half per cent. per annum ?—Yes.

690. Will you give the Commission some information as to the manner in which coal is stored at home

Mr. J. Wright.

15 June 1875.

ports. Is it covered?—In most cases it is covered. At Portsmouth there is no coal store on shore, but there is a large one being built in connexion with the dockyard extension. Some of the coal is stored in the open air in the dockyard, and there are coal hulks and haulabouts that will contain altogether about 10,000 tons. At Devonport there is a store, I do not know the quantity it will contain, but there is an iron building there with openings round the eaves, and there are also coal hulks and haulabouts there.

691. And at Sheerness?—I do not think there is a coal store under cover there, most of the coal however is in hulks.

692. Have you known any instances in the last seven years of combustion in either of those three places?—I do not know of any case of spontaneous combustion having occurred in a coal hulk. With reference to the question, I was asked by Dr. Percy as to whether there was any inspection of coal for iron pyrites. I may mention that in the South Wales district and in the North Country district there is an inspector resident who is supposed to see that the coal shipped is of good quality and free from impurities.

693. (*Dr. Percy.*) All that he does is simply to inspect the coal?—That is all.

694. He does not make any chemical or other examination of the coals?—No.

The witness withdrew.

MR. HENRY JOHNSON McCULLOCH examined:

Mr. H. J. McCulloch.

696. (*Chairman.*) In what capacity are you employed under the Admiralty?—I am consulting coal engineer to the Admiralty.

697. Have you been long connected with the coal trade?—More than 30 years.

698. Will you tell the Commission in what capacity?—I originally commenced my public life as a mining engineer. Then I was for 17 years consulting coal engineer to the Great Northern Railway, in which capacity I had to buy all their coals. Then I left them and became a viewer and consulting engineer on my own account, having under my charge several collieries in North Wales and other places, till I joined the Government seven years ago. In addition to that, I have been for 20 years, and am now, consulting coal engineer to the Madras Railway Company. I advise as to buying their coals, and inspect them, and ship them. I have sent out nearly 400,000 tons of coal and coke to Madras.

699. You have had 20 years' experience in shipping coal for the Madras railway, and six or seven years experience in shipping coal for the Government?—Yes.

700. Can you give the Commission any information as to cases of ignition of coal which have taken place in your experience since you have been connected with the Madras railway and with the Admiralty?—I have only had two cases of spontaneous combustion in shipping coals for the Madras Railway, and singularly enough they were in 1874. I never had a case before 1874.

701. Have you ever had any cases of ignition in shipping coal for the Government?—In shipping the hundreds and thousands of tons of coal for the Government, I have not known the case of a single ship in which spontaneous combustion has occurred, except one, though there have been two or three cases of spontaneous combustion in some of Her Majesty's ships.

702. That is to say, in the coal ships which have carried to foreign ports the coal which you have purchased for the Government, you have only had one case of ignition?—Only one case, and that was in English waters.

703. Will you state the particulars of those three cases to which you refer, two of them being shipments for the Madras Railway, and the other being a shipment for the Admiralty?—In the case of the shipment for the Admiralty the coal was shipped at Cardiff; there had been contrary winds, and the ship was boxing about, and when she was a little beyond the Scilly Islands she took fire.

704. What was the size of the ship?—She was about 800 tons.

705. How much coal had she on board?—About 800 tons.

706. She was full?—I think she was quite full; she was about 500 tons register.

707. Was any inquiry made into the circumstances of that casualty?—No; the men took to their boats; the ship was burnt, and went down.

708. When was that?—It was in 1872 or 1873.

709. Was no inquiry made afterwards into the circumstances?—I never heard of any particular inquiry; it did not come under my notice particularly, for this reason: we buy all our coals delivered at a port; we contract with colliery owners on this side, and we say, At what price will you deliver at Gibraltar? for instance, and they have to effect their own insurance, and find their own shipping, and everything. If they deliver the coal at that port they are paid for it.

710. So that it did not become the duty of the Admiralty to make any inquiry into the case?—No.

711. Did not the Admiralty take any interest in it with reference to the kind of coal purchased, so that it might be avoided if it was found to be liable to spontaneous combustion?—I do not believe that coal could ignite; the casualty must have been owing to something external to the coal itself.

712. What coal was it?—If I mistake not, it consisted of two kinds of South Wales coal, the exact denomination of which I am unable to give. It was shipped at Cardiff.

713. Now will you give the particulars of the two cases you mentioned of coals shipped for the Madras railway?—The first was the "Numea," which sailed from the Tyne on the 1st of May 1874; she had 1,530 tons of coal filled up. The coal was Cowpen Hartley coal. On the 14th of September (according to the official statement of the captain and the notary), when they were near Madras, they observed smoke coming out of the hatches and they immediately proceeded to endeavour to ascertain the cause of it, and they found that the coals, though not in flame or even red hot, were very hot; they poured water on them, and got into harbour without much damage. I investigated that matter thoroughly myself, and I found the reason of the casualty to be what I should have suspected, namely, that water had got into the hold and the coals had become wet.

714. Water had got into the hold on the voyage?—Yes.

715. The coal was shipped dry?—Yes, in the usual way; I suppose it was perfectly dry when shipped.

716. Was the evidence conclusive that water had got in?—Perfectly conclusive.

717. Was there any iron pyrites in the coal?—It is very free from sulphur; it is one of the best coals in the Tyne. There are four or five of about equal value, but I believe it is the freest from sulphur of any one of them, or as free.

718. Passing to the other case, what was that?—The other case was the "Palmyra," which sailed from Liverpool on the 17th June 1874 with 1,206 tons fully loaded.

719. With what coals?—Pearson and Knowles's Wigan Hartley. On the 17th of September, after having had rather a rough passage, they saw smoke issuing from the hatchways; they took the main hatch off, and discovered that the smoke was coming rapidly up, and to all appearance the coal was on fire. They immediately got the donkey engine to work (according to the report which was vouched for in the usual way), and they poured many tons of water on the fire, and then strove to get the coals out. They got about 18 tons of coals out and mastered the fire.

720. What was supposed to be the cause of that?—In investigating that, I found likewise that they had got a lot of water in.

721. That was the captain's explanation, was it?—

He did not seem to want to explain it that way, but I found it out simply by putting certain questions to him and the mates. I felt perfectly sure that unless some unaccountable action had taken place it must have been from water getting in.

722. There was nothing peculiar about the state of the coal when shipped?—Nothing, I saw it shipped, it was shipped at a high level.

723. How many feet did it fall?—The high level is 30 or 40 feet above the quay side, and then they have a crane on the top; they take hold of the wagon and lower it down to about the level of the bulwarks of the ship, and then they take the end of the wagon out, and the coal goes into the hold; the first fall would be, I should think, probably about 26 feet.

724. Then in all your experiences those are the only three cases of coal taking fire spontaneously which you have been concerned with?—Yes, that is so.

725. How many cases of shipments of coal altogether have you been concerned with for the Government, and for the Madras company, speaking roughly?—Several thousands.

726. Therefore the per-centage of cases with which you are acquainted is very small indeed?—Very small indeed.

727. From your connexion with the Admiralty, do you know of any cases of spontaneous combustion in Her Majesty's ships, the coal for use in which you have been concerned in buying?—Only two cases, the "Rattlesnake" and the "Racoon."

728. Were those cases referred to you for report?—The papers came round to me in the usual way.

*729. What were those cases?—They were very slight, the firing took place in the bunkers. I have no hesitation in saying as I said on the minute, that those cases entirely arose from the heat of the boilers, and perhaps a little water had got in. I forgot the "Megæra," that was another case; that was a plain case where a steam pipe went through the coals.

730. That was a clear case of heating from external causes?—A clear case, and the others were I believe the same. A tremendous heat would be caused, and the slightest moisture would assist the action and cause the coal to break into flame.

731. You stated the method in which the coal was shipped in one particular case for the Madras company, are you well acquainted with the way in which coal is shipped at various ports?—I think I am acquainted with the mode in which coal is shipped in every port of Great Britain.

732. How many different ways of shipping coal are there?—A dozen, or more than that.

733. Will you describe the principal methods of shipment?—The best method of shipment of all is that which is adopted on the river Tyne, and at Blyth, and Sunderlands. There they have two methods. The best one of all I will describe first. The waggon comes on to the top of the drops, which are perhaps 40 or 50 feet above the water, the bottom of the waggon is loose, hanging on a hinge on one side, there being two hasps on the other. There is a long telescope spout, and at the bottom of the spout, or near the middle of it, there is a trap to hold a waggon of coals. When they knock out the bottom of the waggon the coals fall out of the waggon close on to the screen, perhaps within 18 inches of it. The coal falls and runs down the incline of the screen until it meets this trap. Then the ship being empty, or thereabouts, they have a large tub that will hold about two tons of coal, a large iron tub worked by a crane, either by steam, or by hydraulic pressure; they lower that down and put it under the spout. They can, if they like, make the spout reach down to the deck, or close on to the hatchway, but in this case they do not do that; they put the tub under the spout, open the trap, and fill the tub. The tub, when filled, is lowered right down to the bottom of the hold. It has a trap at the bottom, and the man who goes down with it just draws out a pin, and the bottom falls out and delivers its coal without any breakage.

734. That you consider the best method of shipping coals?—Yes.

735. Why?—Because it does not break the coals at all. The larger the coals the greater their value, and the less danger there is from fire. Then, when the coal comes up nearly to the top, they lower the spout down—I said before that the spout was a telescope,—and they run the lower part of the spout on to the deck; then they have a piece of sheet iron close to the deck, forming an acute angle, and the coals as they fall on this piece of sheet iron run down on each side, and the trimmers take them away on each side, right and left.

736. That, you consider is the best method of shipping coal, and spoils it the least?—I do.

737. Will you give us two or three other methods?—Then there is another method in use in those three places, which is by what they call swing drops. That method is adopted in the Tyne and Sunderland, but not in Blyth. They have a drop made with arms, on to which the waggon runs; and there is a counter-balance just to balance the weight of the waggon when the waggon was empty, so that when the coal was out of the waggon the counter-balance would bring the waggon up to bank again. They have a wheel and a break on it, and when a full waggon comes on, it goes down by its own gravity, and to hinder it from going down too quickly there is a man who has a break, and he applies the break sufficiently to let the waggon lower itself down gently till it gets down as far as the swing will allow it in its curve to go. Then, when it gets there, the same process takes place as in the case of the tub, they take out the pins and take out the bottom of the waggon, and the coal drops right into the hold, but it is close on the top.

738. That you consider a safe and effectual method of shipping coals?—I prefer the other, infinitely, but still it is the second-best method.

739. Will you give us one or two more?—In some places, in South Wales and in other places, of course they have nothing but the screen. They have a tip, but that tip is about 8 or 10 feet from the top of the deck; in some instances 6 feet, and all the coal must fall down that distance into the hold.

740. Is that the usual method adopted in South Wales?—Yes.

741. Do you consider that, with regard to the point which this Commission is specially looking into, it is safer and more advantageous to shoot coal according to the first method you have mentioned?—I do, and I will show you why I think so. Small coal falling into a ship becomes compact and dense, and therefore more capable of excluding anything like air. The more crevices that are left between the pieces of coal, the better it is, and the more opportunity there is for the air to circulate around the coal. Of course it is the want of air in my opinion that causes the combustion.

742. You consider that the better the coal is ventilated the less likely is combustion to take place?—Yes.

743. Will you give us some information also about the transport of the coal from the pit to the place of shipment. Has there been of late years much change in point of time in the transit from the pit to the place of shipment, or in any other respect?—Within the last 15 or 20 years there has been a great gain in the time of the transit from the colliery to the staith, but I am not quite so sure whether that has not been counterbalanced by the immense exportation. For instance, 20 or 25 years ago they were all small waggons that were used, what we call chaldron waggons, but of late years we have had 10-ton waggons. The larger the quantity in the waggon, the worse for the coal, in my opinion.

744. Do you think that the employment of large waggons increases the risk of combustion?—It breaks the coal more.

745. The coal is not now so long exposed to the air as it used to be?—Perhaps not.

---

* *See* Admiralty Inquiry, page 62, which shows that Mr. McCulloch, in this, and in his next answer, was mistaken.

Mr. H. J. McCulloch.

15 June 1875.

746. In that respect is there a gain or a loss?—A gain, I think.

747. It is not so long exposed to moisture?—It is not so long exposed to moisture.

748. Going generally into the question referred to the Commission, what do you conceive to be the principal causes of spontaneous combustion of coal in coal-laden ships?—I look upon it that there is only one thing that can properly account for it. Very often I have seen coals put on board ship in a most lubberly way; that is to say, I have known the sides of the ship to be wet and damp, and sometimes I have even known water to be in the ship, quite apart from any moisture in the coals themselves, and my experience teaches me this, that if coals are even moist, much less damp, the bi-sulphide in the coals (because all coals have it, saving perhaps the hard coal of South Wales, the anthracite coal; except that coal I know of no coal that is free from sulphur) becomes, through its oxidization, turned into sulphide of iron by a natural process, and during that time, naturally, sufficient caloric is generated to cause combustion in the carbon of the coal.

749. Your opinion is that all spontaneous combustion of coal is caused by moisture, and that all coal is liable to spontaneous combustion?—More or less, except anthracite.

750. You do not believe that perfectly dry coal ever takes fire spontaneously?—I do not believe it.

751. Do you think that the number of cases of spontaneous combustion has been greater in the last two years than it was before?—Yes, I believe so.

752. The only two cases you have mentioned as having occurred within your own experience were last year?—They were last year.

753. How do you account for that?—It is partly to be accounted for, I think, by the immense increase in our exports. They have increased marvellously, and of course as the number of ships increase, the number of cases of spontaneous combustion would be likely to increase in the same ratio; but my impression is that there is a great deal of carelessness in the shipping of coal, and that there is no means of ventilation.

754. Do you think that there has been greater carelessness of late years?—I believe so.

755. Have you any evidence of that?—It is only an impression; more ships have taken fire within the last 10 years than perhaps in the century before.

756. You say that there has been greater carelessness, and also less attention to ventilation; do you believe that in a given number of ships there are fewer that are well ventilated than there used to be?—I do not think there are any ships that are ventilated; or if they are, they are so badly ventilated that the ventilation is not worth speaking of.

757. Your impression is that coal-laden ships are not, as a rule, well ventilated?—I think they are not well ventilated. I may say that they are not ventilated at all.

758. Do you say that absolutely as to all of them, or as to the great majority?—The great majority of them come under my own observation, and I have also seen many that I have had nothing to do with. I happened to be in Liverpool some two or three years ago, and I was talking to a shipowner who was there, and expressing my views as to ventilation. He misunderstood what I said to him on the matter evidently, because he went and had his ship ventilated, but instead of making the uprights as I advised him, and the trunk as well, he bored holes in his ventilator, and when the coals went in, the small coals went into the holes, and stopped all the ventilation.

759. What in your opinion are the precautions which should be taken, and which are not taken now, to prevent the spontaneous combustion of coals in coal-laden ships?—I think the remedy is very simple. From the deck I would put in a ventilator, of a size varying according to the size of the ship, in the forward part of the ship, so as always to be open to the breeze. I would carry that down into a large horizontal ventilator below, that would run the whole length of the ship; and at intervals, according to the size of the ship, I would place upright shafts 8 or 10 inches square, with louvres, so that, supposing they were 20 feet apart, if the coals were to heat even from damp of course the heat would always ascend, and it would come into these louvres because they would be all open; it would come right up through the body of the coal, and it would escape, and so keep the coal comparatively cool. This would go through the hatchways into the open air. That would not cost much, and any impression is that it would be a perfect preventative of heating.

760. You have stated already that in respect of ventilation coal-laden ships are deficient; would you impose upon them the necessity of adopting some such system as you recommend, by law?—Yes, and it would save their pockets. Whether the ventilation is made of wood or iron, I do not care. Some may fancy that to make the ventilation of wood would be adding fuel to flame, but I do not think so, because I believe it would keep the ship perfectly free from danger.

761. Have you any suggestions to make as to the best method of extinguishing fire on board coal-laden ships?—I see no other method but the old-fashioned one of water. If you could hermetically seal the bulkheads and the hatchways, we could find a very speedy way of extinguishing it with carbonic acid, but I think it is impossible practically to do so.

762. You mean with the extincteur?—Yes.

763. (*Mr. Vivian.*) What is the form of the waggons which are used on the Tyne, are they not conical at the bottom?—No, as a rule the bottoms are flat.

764. Do not the sides slope to the centre?—Yes.

765. And the ends slope to the centre?—Yes.

766. So that they are conical?—If you turn them upside down they are. When I speak of a conical waggon I mean a waggon in which they have a cone in the bottom.

767. I mean the sides and the ends slope towards the centre?—That is so as regards some of the waggons.

768. All the waggons are so constructed, are they not?—Not half of them.

769. Then how can the bottom clear the axle-trees?—It is in between them.

770. There are two classes of waggons on the Tyne, namely, end-board waggons and bottom-board waggons?—Yes.

771. I understood you to speak entirely of bottom-board waggons?—No; I said they tipped the waggons up at the end as well.

772. I understood that to refer to another species of tipping. Speaking of the Tyne mode of tipping, which you say you believe to be the best, the ends and sides of the waggons fall towards the centre?—Yes.

773. Then those waggons may be called inverted cones?—Yes.

774. You are acquainted with the South Wales coals, no doubt; is it possible to ship South Wales coals with waggons of that character?—Yes.

775. Have you ever seen it done?—No, because there are no waggons of that class in South Wales.

776. The blocks of South Wales coals are very large, are they not?—Yes.

777. Can you state, of your own knowledge, that they would pass through the bottom of those conical waggons?—I think they would.

778. Have you ever known them do so?—No, because there are no conical waggons in South Wales. But I have seen this done; I have seen large blocks of splint coal come out of those waggons, some of them 2 feet long by 15 or 18 inches thick, readily. A piece of coal may stick a little, but the men are prepared with what they call a prod, and they ease the piece of coal, and away it comes.

779. You have no practical experience leading you to say that it is practicable to ship South Wales coals in those conical waggons?—No, because I never saw a conical waggon in South Wales.

780. With regard to swing drops. You have seen

Mr. H. J. McCulloch.

15 June 1875.

them only on the Tyne, but are you aware that there are swing drops also in use in South Wales ?—There are some at Swansea now.

781. And have been for a good many years ?—Yes, at Swansea.

782. There are none at Cardiff ?—I think none.

783. At Cardiff end-board waggons are used entirely ?—They are all end-board waggons there.

784. The system is to drop the end of the waggon and let it discharge itself on to the shoot, is it not ?—Yes.

785. Then in what does that differ from the Newcastle system ?—Only in the delivery from the shoot into the hold.

786. In what does it differ from the swing-drop system that you said you have seen in use at Sunderland ?—Somehow or other they do not bring their swing drops in South Wales sufficiently low down.

787. Do not they bring them simply to that angle at which the coal will run down ?—The waggons are not used in this way in the swing drops that you are speaking about.

788. In what way does the swing drop of the Tyne and the Wear differ from the lowering drop used at Cardiff and Swansea ?—The one goes so much lower on to the deck than the other.

789. The end of the shoot goes equally on to the deck in both cases, does it not ?—In the swing drop there is no shoot used at all.

790. Then how do you double screen into the ship ?—I think that is obsolete ; at least, I hope it is. It is obsolete as far as the Admiralty is concerned. I tried to stop that waste of coal (beside the cost of 1*s.* more per ton) very soon after I took office.

791. You disapprove of the system of double screening ?—Decidedly ; it makes the coal worse, and is expensive.

792. The system adopted at Cardiff and other South Wales ports is to have the waggon and the shoot only at such an angle as to enable the coal to run, is it not ?—That is the principal way.

793. So that it is subjected to no more pressure than is necessary to cause it to run ?—Just so.

794. Is there not a check-board across the shoot to prevent its running down too quickly ?—Yes, there is a trap.

795. Are you acquainted with the system of shipping coal at Swansea ?—Yes.

796. Do you know the box system ?—Yes.

797. You did not mention that ?—No ; because the box system is like the tub system, only more clumsy.

798. That is an entirley new system, adopted by the Great Western Railway, and worked by hydraulic power arranged by Sir William Armstrong ?—Yes.

799. Those boxes lower the coal through the hatchways into the hold of ship ?—Some of them do.

800. The bulk of them do ?—Yes.

801. In what way is the Newcastle system better than that system ?—In the first place, the tub in the one case holds so much more than the box ; in the next place, the system is adopted at Swansea to a very limited extent only.

802. You said that the tub held two tons ?—Two or three, or four tons.

803. The limit is the size of the hatchway ?—Yes.

804. The South Wales tubs are as large as the hatchway will take, are they not ?—They are like boxes. The Newcastle tubs are iron tubs.

805. The Swansea box would hold two and a half tons, would they not ?—Yes.

806. That box is lowered through the hatchway into the hold ?—Yes.

807. And the bottom of the box is struck out ?—Yes.

808. Is not that a good system ?—It is a good system, but it is only adopted to a limited extent.

809. Is not there this advantage in that system over the Newcastle system, that it saves one breakage of the coal ? In the Newcastle system the coal has to be discharged from the truck into the shoot, and then from the shoot into the tub ; whereas, in the South Wales system, the coal comes direct from the colliery in the box, and that box is lowered into the hold of the ship, so that there is one breakage less ?—If you look at the coal which is shipped by that method, you will find that it is the soft coals ; none of the best steam coals are shipped from South Wales in that way.

810. Was not the whole of the coal on the Vale of Neath system worked in that way ?—No ; at all events it is not so now ; the tubs are in existence, but they are principally used for this soft coal.

811. Do you find generally that the coal shipped on the Tyne is discharged in better condition than the coal shipped in South Wales ?—No, I would not say that, for the simple reason that the best steam coals in South Wales are so large that they come out larger than north country coals ; but taking the coal all round, they come out with a less per-centage of small in the north country than in South Wales.

812. Do you think it would be desirable that the system of shipping coals adopted in the north of England should be introduced into South Wales ports ?—I do.

813. Do you know the system adopted at the Alexandra Docks at Newport ?—I do not know it. I saw the docks opened, but I did not go round to look at the drops. I believe they are on the same principle as the drops in the Tyne and the Wear.

814. The system adopted at the Alexandra Docks is considered to be the very best system of shipping coals that can be adopted, is it not ?—I believe it is precisely the same in principle as that adopted in the Tyne.

815. You approve of the plan of lowering a tub containing the coal down through the hatchways ?—Yes.

816. Till a column is formed ?—Yes.

817. And then lowering the waggon down to the hatchways and discharging it as gently as possible ?—Yes ? the tub will lower the coal till it comes right up to the hatches, and there will be sufficient room on each side for the coals discharged on to the piece of sheet iron to slip away to each end where the trimmers can get hold of them.

818. You said that all coal contains iron pyrites. Some coal is what they call white ash coal, is it not ?—All the best bituminous steam coal is white ash coal.

819. Is it possible that that can contain iron pyrites ?—In my opinion it does.

820. Supposing it to contain iron pyrites, what becomes of the iron when burnt ?—I daresay chemists would find it somewhere. I am not a chemist, but I have seen certain things take place, and I have drawn my own conclusions from them. It may not be in the form of iron pyrites, it may be in the form of sulphur. Iron pyrites may exist in the coal, and not be in the form of brass. Brass is usually the form of pyrites in North and South Wales, but there is sulphur in the coal, though there may not be the brassy appearance.

821. It must be in the condition of pyrites, must it not ?—Of course it would be pyrites, but it would be in such a form that perhaps you would not find it. I can only say that the best steam coals in the north country go to white ash, and that I can positively say, because I have stood by a chemist when he has been analysing them. I can positively say that there was iron pyrites in those coals, and yet I could not distinguish it. A chemist might distinguish the presence of a small quantity of iron pyrites, though I could not.

822. Iron pyrites when burnt must produce oxide of iron in the first instance which would produce a red ash ?—Suppose you had ·50 or ·60 of iron pyrites, how would you distinguish it ?

823. The quantity is so infinitesimally small, that it may be disregarded ?—No. Though the quantity of it in the coal may be so small, if the coal is made wet it will do its work. I would not buy a single coal if I had my own way that contained over 1 per cent. of iron pyrites, that is to say, for certain purposes.

Mr. H. J. McCulloch.

15 June 1875.

According to our investigations we have never found in the best Welsh coals more than 1·20 to 1·50.

824. Is that sulphur or iron pyrites?—Iron pyrites. It is the same thing.

825. Iron pyrites is sulphur combined with iron, and sulphur is sulphur alone, is it not?—But they are in close brotherhood.

826. You consider that all coal contains iron pyrites?—Yes.

827. And that all coal is liable to spontaneous combustion if it is wetted?—I think so, save and except anthracite coal.

828. If anthracite coal contained iron pyrites, would not that be liable to ignite spontaneously?—Some of it does not contain any, some of it is nearly pure; and, besides, it is like stone.

829. Are you aware that anthracite comes from the same veins as the steam coal, only more to the westward?—I am perfectly aware of that, but there is a distinct difference in the strata.

830. In what respect is there a difference in the strata?—You will find a great difference between the steam coal and the anthracite. As you go north from the Aberdare Valley the coal becomes more and more anthracitical all the way up till you get right over the mountain.

831. In what way do the strata differ?—I mean the superincumbent strata. If you were sinking a pit higher up, you would find the strata different to what you would if you were sinking to the 4-feet seam lower down the valley.

832. (*Mr. Cory.*) I understood you to say that the Cowpen Hartley was more free from sulphur than any of the other Tyne coal?—I said three or four of the best coals were about on a par.

833. You did not intend to say that Cowpen was more free from sulphur than any of the rest?—No. I qualified that by saying there were three or four equally good.

834. Did you ever know of any ship ventilated on your plan?—One has gone out to Madras from Liverpool a little while ago ventilated in that way.

835. Exactly upon your plan?—Not exactly, but an imitation of it. It was not exactly carried out as I should have liked to see it done.

836. Is she a coal-laden ship?—Entirely a coal-laden ship.

837. Is that the first ship you know of that has adopted your plan?—The first I know of.

838. What is the name of that ship?—The "Maori." I may say that this ship sprang a leak after being about a fortnight out, and they had to come back again and discharge her coals, and reload fresh coals.

839. (*Mr. Icely.*) What form of iron pyrites distributed through coal do you consider to have the most dangerous tendency?—I do not care whether it is iron pyrites or sulphur; if there is any difference, in my opinion they both tend to the same thing.

840. There are some varieties of coal which you consider especially dangerous?—Yes, there are some coals very dangerous.

841. And you reject those in your selection of coals for the navy?—Yes.

842. Could you name any of them?—I should not like to name them.

843. After you have made a purchase of coal, is not there a coal viewer at the ports to inspect the coal?—Yes, a coal inspector at each of the ports.

844. What are the instructions which the Government give him in inspecting coals?—He is particularly ordered, first, to watch the proportion of small; secondly, to see that they are kept clear of slate and stones and other impurities, and thirdly, to see that all the brasses are picked out if possible.

845. If, for instance, he observes that the coal is dirty and small, has he the power to reject it?—Yes.

846. Or to prevent the shipment of that cargo?—At once. In all our tenders we make that a *sine quâ non*.

847. Do you attribute to this careful inspection the comparative safety with which cargoes of coal for Admiralty use have been carried?—I have no doubt a great deal of it is owing to that.

848. (*Mr. Young.*) What kind of coal was it that was shipped in the "Numea" in May 1874, that took fire?—Cowpen Hartley.

849. You said you investigated the circumstances both of that case and of the "Palmyra." What do you mean by investigation?—I made inquiries of the captain and the crew by their report.

850. After they came home?—Yes.

851. You read the protests and saw the captain and the crew afterwards?—I read all the protests and had to make out a regular statement for the underwriters.

852. And you saw the captain and crew after they came home?—I saw the captain and crew's reports. Perhaps I may here refer to a question which the underwriters raised. They got into their heads that the cause of the fires being now so numerous was that the coals were shipped direct from the pit into the ships, whereas formerly they used to be laid in heaps. Some of Lloyd's people asked me whether I did not attribute it to that cause, and I said it was a perfect fallacy. I said I would look upon dry coals shipped direct from the pit as being infinitely more safe than coals that have been lying in a heap; and moreover they would become completely valueless by being exposed a long time to the wind and the rain and the air, because their virtue would be gone to a great extent.

853. Have you known cases of spontaneous combustion of coals stored on shore?—Many cases.

854. More frequently than on board ship?—More frequently than on board ship.

855. You said that want of air causes spontaneous combustion?—Want of proper ventilation, not want of air exactly.

856. Spontaneous combustion could not take place without air?—There is always sufficient air in a ship; you cannot hermetically seal a ship.

857. (*Mr. Abel.*) You have given us only three cases of spontaneous combustion on board ship; those are the only cases that have come to your knowledge in all your experience?—Those are the only cases that have come directly under my own cognizance.

858. May we take it that these are really the only three cases that have occurred in all the shipments of coal with which you have been concerned?—You may.

859. Would you necessarily hear of every case of spontaneous heating of coal on board any ship carrying coal under contracts?—Certainly.

860. How would it come to your knowledge?—It would come to my knowledge by a complaint being made. If coals get heated they become discoloured, and though they may not be very hot, yet they are so discoloured that when they are inspected at the dockyard, or wherever they are landed, they are reported on; and those reports have always come before me for my opinion, that is as far as the Admiralty is concerned.

861. Therefore any case in which any real damage was done would come to your knowledge?—Yes, and the same as regards shipments for the Madras railway.

862. Supposing a case of heating occurred, but no damage was reported as having been caused to the cargo, you would not hear of it?—No, we have such a system that they are not apt to report cases of heating of coal of trivial importance, because coal cannot become heated without destroying a portion of it.

863. Those three are the three important cases of heating on board ship that have come to your knowledge?—Yes.

864. Personally, you have no positive knowledge of the cargoes of coal that those ships took out?—We have an inspector at each part who inspects the coal. I do not go to inspect each cargo. I know what kind of coals we purchase.

865. As regards one of the three cases which you

Mr. H. C. McCulloch.

15 June 1875.

mentioned, I understood you to say that, speaking from your own knowledge, the coal was practically free from pyrites?—I have just told Mr. Vivian that I believe in all coal there is pyrites sufficient to cause spontaneous combustion under certain circumstances.

866. I think in the earlier part of your evidence you stated, with reference to one particular cargo, that to your knowledge or belief there was no pyrites in that particular class of coal with which the ship was laden?—I think I said that the particular coal I referred to was as free from pyrites as any coal.

867. Your view with regard to spontaneous combustion of coal on board ship is that it is entirely due to coal getting wet?—Entirely.

868. You attribute it to no other cause?—There might be another cause—red hot ashes put on it might cause it to ignite.

869. You think every coal is liable to spontaneous combustion?—Every coal except anthracite.

870. And you consider the only point to be guarded against is to keep water from the coal?—I do.

871. You spoke of the explanation the captain gave with regard to one of those cases of spontaneous combustion with which you did not agree; what was the captain's explanation?—I did not mean that the captain attributed the casualty to anything but water getting in. He said he was perfectly sure no moisture had got in amongst the coals unless, as he said, it had got in through the crevices of the deck or somewhere else in such a proportion that it could not do any harm. He wanted to show that the quantity of water had been so small that it could not do any harm. If what he had stated was true it could not have done any harm. No doubt a very small quantity on the top of the coals would not do much harm, but there was more than that; and in fact he admitted afterwards, in his report, that in a storm no doubt water got down somewhere or other, through the scuttles, or somewhere.

872. Do you think it is possible to prevent coal containing water when placed on board ship, even if placed there directly it leaves the pit's mouth?—I believe chemically all coal contains a certain quantity of water, but I do not believe there is sufficient water in coal internally to make it at all liable to spontaneous combustion.

873. You said that the larger the waggon the worse for the coal; will you explain what you meant by that?—Simply because one waggon will contain 2 tons 13 cwt. and the other will contain 10 tons. If a heavy shower of rain were to come on to those coals contained in the 10-ton waggon there would be a larger surface of coal exposed than in the other case, and if the coal were to be exposed long to the air it would destroy the coal. If you expose coal to wind and rain you destroy its power in a great measure. That was what I meant, that the waggon being larger, more surface was exposed.

874. (*Mr. Ferguson.*) Seeing that you attribute spontaneous combustion to water mixing with the coal, is the system of ventilation which you propose solely to counteract the dampness of the coals?—It would carry off the heated atmosphere from whatever cause.

875. I understood you to say that spontaneous combustion was only caused by the coals being damp?—That is my opinion.

876. Therefore your system of ventilation would be to counteract that?—Certainly.

877. In the many thousands of tons of coals that you have shipped, have all the vessels which have carried those coals without damage been ventilated in that way?—Not that I know of.

878. Have they been ventilated at all?—Not that I know of.

879. With regard to the vessels in which you say the heating was caused by water getting in, did that water come from above or below?—It came from above, I believe, in both cases.

880. From the quantity of coal you ship for abroad you must be aware, I suppose, of the extent to which the coal depreciates after being carried a few months in the ship's hold; if 10 tons of coal will do a certain amount of work here, will it do the same amount of work when it arrives at its destination?—You must take a little per-centage off for the breakage, but apart from that it really suffers very little harm, it does the same work and evaporates the same amount of water. If you stack it in the sun and rain for a month you will take away 10 per cent. of its value at once.

881. Do not you find that the gas accumulates in the ship's hold during the passage, and does not the coal thereby lose some of its combustive power?—No; I think the best steam coal retains its gas in its integrity.

882. Is it not the fact that coals lose their combustive property to a great extent in the course of the voyage?—Very little. There is no way of escape for it.

883. (*Mr. Duncan.*) You have described a method of ventilation which you think would make ships perfectly safe from spontaneous combustion?—I think so.

884. In describing that mode of ventilation I understood you to say that you would have a horizontal shaft in the centre of the ship?—Yes.

885. About what size?—According to the size of the ship.

886. What would be the size of the shaft for a ship 1,000 tons register?—I should say a couple of feet square.

887. You would have that go right along the centre of the ship?—Right along the centre of the ship.

888. Not quite in the centre, because you would have to keep clear of the iron stanchions that go up and down?—You could not lay it along the keelson, but I should prefer it being about 3 feet from the bottom, just laid along the whole length of the ship; then I would have a connexion at each end with the deck, so that the air might come down. There would be a funnel forward going up above the deck as they have for ventilating the cabins and holds of ships, so that it would catch the air and draw it into this shaft; by that means there would be a continual current of air. I would have upright shafts at certain distances made with louvres, so that the air would pass along each one of those continuously. Then if there were any heat it would pass up through those louvres into the open air.

889. You would carry these louvres 4 or 5 feet above the deck, so that in all weather they would be open?—Yes; but loaded so that water could not get admission.

890. Would it alter your judgment in reference to the safety of your plan if you were told that it had been stated to this Commission that spontaneous combustion had taken place in ships ventilated in that way?—It would not at all, because I know that ships that have taken fire have not been ventilated.

The witness withdrew.

Mr. Samuel E. Derry examined.

Mr. S. E. Derry.

891. (*Chairman.*) You were, I think, from 1859 to 1868, inspector of coal shipped for the Admiralty in South Wales?—Yes.

892. What was your district?—All the ports of South Wales.

893. You are now an engineer in the service?—I am a retired chief engineer in the Navy.

894. During that period, from 1859 to 1868, you had some experience of cases of spontaneous combustion?—Three cases; they were all one description of coal.

895. What was the coal?—Parsons Abbey Graigola.

896. All the three cases of spontaneous combustion

Mr.
S. E. Derry.

15 June 1875.

which came within your knowledge were of that one description of coal?—Yes.

897. Will you give to the Commission some particulars of those cases?—In 1864 a complaint came officially before me with regard to coal having caught fire at Jamaica and Barbadoes, and also in a vessel arriving while they were extinguishing the fire at Barbadoes with the same coal on fire on board of her.

898. Were those cases all in the same year?—Yes, in 1864.

899. How long had the ships which carried that coal been out?—I should think about six weeks.

900. Those were the only cases which came under your knowledge in your 10 years' experience?—Those were the only cases of spontaneous ignition that came under my official knowledge during the whole of that time; but I think the same coal caught fire in Keyham Yard at the same time.

901. That was not within your official knowledge?—No.

902. What is the character of that coal?—It is a smokeless coal from Llansamlet, not produced in the regular steam coal district.

903. Was it shipped under any particular circumstances?—Not at all.

904. Was it shipped in fine weather?—I do not think the weather would have anything to do with it. I think the same coal would catch fire under the same conditions if sent out again.

905. What is the chemical character of the coal; does it contain a large proportion of iron pyrites?—It is not that the iron pyrites is in a large proportion, but it is so intimately mixed with the coal as to be in a most favourable condition for catching fire. If you took a piece of coal from that vein you could see that the coal and the iron pyrites were intimately mixed, perhaps there would be an eighth of an inch of iron pyrites and an eighth of an inch of coal, and so on, as if laid alternately on purpose to facilitate its catching fire. In other steam coals there is plenty of iron pyrites, but if it is localised in large masses it is not so likely to take fire as where distributed in the manner I have mentioned.

906. Was this coal shipped smaller than the average of South Wales steam coal?—It naturally works smaller than the average of South Wales steam coal.

907. Otherwise there was nothing peculiar either as regards the length of time that it was exposed or as regards moisture, which it was subjected to?—Not that I can remember.

908. Nor was there any report made showing that during the voyage anything occurred which might have pointed to the cause of the coal catching fire?—No; the fact of the coal catching fire in so many different directions at the same time would appear to indicate that it was in the nature of the coal itself and not in any particular circumstances connected with it.

909. Did you in the course of your official duty lay down any particular regulations in connexion with the shipment of coal?—I did. I put the conditions for the shipment of coal for the Admiralty in South Wales into order. The conditions I laid down were that the coal should be free from small at the time of shipment, but of course one necessary condition is that the coal must be clean, that is to say, free from large quantities of iron pyrites. You cannot get coal perfectly free from sulphur, but it must be free from large quantities, and it is required to be free from small coal. Those were the stipulations that I had to see fulfilled.

910. Was there any stipulation in the contract as to the ventilation of the ship?—None; it did not become necessary for the Admiralty to look into such regulations as that, for if the coals were not supplied at the port, the Admiralty did not pay for them.

911. They were paid for on delivery?—Yes.

912. Still the Admiralty were interested in the coal that they required for a particular station not disappearing on the way?—So far as keeping up the supply went they were interested.

913. When those casualties took place was the matter referred to you?—It was.

914. In each case you satisfied yourself that it was the fault of the coal?—Yes.

915. And not the fault of the ships?—Not in any way.

916. (*Mr. Vivian.*) How much of this Parson's Abbey Graigola coal did you ship?—2,000 tons I should think, at least that?

917. It fired in three cases?—Yes, at the stores in the dockyard at Jamaica; at the stores in the commissariat department at Barbadoes, and also in a vessel arriving at Barbadoes while the coal was on fire on shore with the coals on board on fire.

918. What quantity out of that 2,000 tons would that represent?—Perhaps nearly half the quantity.

919. There are considerable quantities of that coal shipped are there not?—They have one particular vein, the coals from which are liable to take fire spontaneously.

920. What is that?—The Tyr Edmond. When they do not ship the Tyr Edmond the coal is free from danger, when they do I think it is certain to ignite.

921. Had the coal been long on the bank before being shipped?—No, it never is.

922. Was it wet or dry?—I cannot remember whether it was rainy weather or not.

923. That is the only South Wales coal which in all your experience you have found liable to spontaneous combustion?—Yes; it depends on the condition of the coal. In the case of all coal where the coal is small the particles of sulphur get more intimately blended with the coal, and in this particular coal ignites spontaneously; but I never heard of good marketable South Wales steam coal catching fire spontaneously in the main body of the coal?

924. How much coal did you ship altogether during the 10 years you were in South Wales?—It must have been millions of tons. I shipped 27,000 tons in one month.

925. Out of the millions of tons you shipped only those three cases of spontaneous combustion occurred?—That is all.

926. Did you ship any patent fuel?—Yes.

927. Have you known a case of spontaneous combustion in patent fuel?—Never.

928. (*Mr. Icely.*) Have you ever inspected jettisoned cargoes in cases where spontaneous combustion has occurred in other vessels not connected with the Admiralty?—Never. I never knew South Wales coal catch fire except in those three instances to which I have referred.

929. Did you never know of any other case of heating in South Wales coal?—No. I have known of explosions of gas in vessels, not spontaneous ignition.

930. (*Mr. Young.*) Are those explosions noted? Do they come under your notice?—No; those explosions have not been in the case of any cargo that I have had officially to do with, but when they improperly put on the hatches before the cargo has had time to give off its gas, an explosion takes place now and then; the gas ignites.

931. When a light is put to it?—Yes. It is not uncommon for a vessel to come back to Cardiff after it has got out into the Bristol Channel.

932. On account of damage having been done by explosion?—Yes, the coal gives off gas.

933. Does that refer to all kinds of South Wales coal?—I should think so. You may see the coals giving off the gas in the pits.

934. You think it is a very important thing to keep the hatches off in all vessels?—It is a standing order in the docks, but which is disobeyed very frequently.

935. Do you think ventilation would do away with that danger of explosion?—I think ventilation is absolutely necessary.

936. You have mentioned three cases in which this coal took fire. Did you ship any more of that same coal after that?—No.

937. You ceased shipping that coal at once?—Yes.

Mr. S. E. Derry.

15 June 1875.

938. Have you had any remonstrances from the colliery owners for tabooing them in this way?—The colliery owners were only too glad to be quiet under the circumstances.

939. (*Dr. Percy.*) Could you give us a specimen of this coal?—No, I cannot furnish the Commissioners with a specimen.

940. (*Chairman.*) Is the seam still worked?—I do not know.

941. (*Dr. Percy.*) I think you said that the danger of spontaneous combustion was lessened by the small coal being separated from the large coal?—Yes.

942. If so, can you assign any reason for that?—I have tried to assign a reason for the fact that the presence of small coal is liable to assist spontaneous ignition, and I think it is because in the small particles of the coal the sulphur and the coal become more intimately mixed together, and then the coal is in a more favourable condition for catching fire than when the pyrites is in large masses.

943. Do you know whether any investigation has been made by the direction of the Admiralty with regard to the proportion of iron pyrites in small coal as compared with large coal?—I am not aware of any.

944. You spoke of the mode in which the iron pyrites was intermixed with this coal. You spoke of the mixture as being intimate?—Yes, there would be a thin layer of coal and a thin layer of pyrites.

945. Would you call that an intimate mixture?—Yes.

946. Is not there plenty of coal in which the iron pyrites is diffused so minutely that you cannot see it?—Yes, and it is not dangerous then, I should think.

947. What was the thickness of the layer of iron pyrites which you saw?—The layers varied. Perhaps on an average they would be about an eighth of an inch.

948. Was the layer pretty continuous throughout?—It was not straight.

949. Was it all through the coal; did all the lumps contain it more or less?—Yes. I think it was pretty well distributed throughout the whole of the coal of that vein. There were coals of two veins in the cargo; but in the case of that vein I think the iron pyrites was pretty well distributed throughout.

950. What examination was made by the Admiralty of that coal before it was ordered?—Only the examination I made of it at the time of shipment.

951. Simply an inspection?—Yes.

952. Was any test taken of its heating power?—Yes.

953. Was there any other examination made of it?—No. In fact any trials of the coals would be to a certain extent fallacious; for supposing the cargo to consist of coals from two veins, it is easy to send the best for trial, and to send the coal from the other vein for shipment.

954. Is any examination made on the part of the Admiralty with the view of ascertaining whether coal which is being shipped for the use of the navy contains iron pyrites?—In all cases before coal was admitted for Admiralty use it was sent to the dockyard for trial.

955. In the particular case of which you have been speaking, was the proportion of pyrites contained in the coal directly ascertained or not?—Not at all. I think it exceedingly probable that no coal containing pyrites was sent for trial at all.

956. Is any examination made of coal at the Admiralty with respect to the proportion of pyrites contained therein?—Now I have nothing to do with it; I have ceased to have anything to do with it for five years.

957. In your time was it the practice to have an examination made with a view of ascertaining the proportion of iron pyrites contained in coal?—I merely went on my own judgment by inspection.

958. (*Mr. Duncan.*) In your judgment the circumstance of the coals getting wet in the wagons between the time of their leaving the pit's mouth and of their being put on board ship was not a matter of serious importance?—I think it would assist to set up spontaneous ignition if the coal was shipped wet.

959. Are you able to explain at all what the action of wet upon coal is?—I am not a chemist. I only know that it is desirable to avoid shipping coals containing an excessive amount of sulphur.

960. Have you any reason for thinking that the application of water to coal is likely to induce spontaneous combustion?—No; I only know that it is the generally received opinion that moisture superinduces heat.

961. You have no practical experience in that direction?—I have not.

962. (*Chairman.*) Is it your impression that coal containing iron pyrites distributed in the manner you have described will burn spontaneously without moisture, or is it your impression that moisture is a necessary element?—Supposing the iron pyrites to be so mixed in the coal as to cause the coal to be in a state favourable for spontaneous combustion, then I think that either damp or friction will cause spontaneous ignition. I think friction might cause it in the working of the vessel at sea in the same way as striking a lucifer match.

963. (*Mr. Duncan.*) From your observation of the lumps of coal when they have been coming down for shipment, is it your opinion or not that the pyrites is lying on the surface of the pieces rather than in the centre of them?—No; I do not think that the iron pyrites is present in one part of the coal more than in the other. I think coal brought from any particular part of a seam is equally liable to contain iron pyrites as coal brought from any other part of the seam. I have noticed pieces of coal which bore signs of having been wrought from the bottom or the top of the seams, but I do not think that they gave any particular indications of sulphur.

964. You do not think that the dust coming off the top and the bottom of the seam would contain a larger proportion of iron pyrites?—I do not suppose my opinion upon the point is of much value; but I think the pyrites is distributed through the whole of a seam, here, there, and everywhere. I think there is no rule for it.

965. You do not think that there is more pyrites among the small than among the large coal?—No, not ton for ton.

966. (*Mr. Vivian.*) I think you said that the small of the steam coal in your judgment was liable to spontaneous combustion?—More so than the large.

967. You have been at Aberdare?—Yes.

968. Formerly large heaps of small coal used to lie at the pit's mouth, where it was subjected to the very best conditions for catching fire, the small coal being exposed to the weather for many years?—Yes, for 10 or 12 years.

969. So that if the small coal were liable to spontaneous combustion it surely would have taken fire in that case?—It is not generally liable to fire; still, I have seen it on fire, and at the docks too.

970. Do you mean small coal?—Yes.

971. Are there any large heaps of small coal at the docks?—There used to be large accumulations in my time. When they began to screen coals they had a large quantity of small after screening, and it lay there perhaps some months.

972. You have seen that in some cases on fire?—Yes, and in the collieries in the Aberdare valley I have seen small heaps on fire.

The witness withdrew.

Mr. Orestes Brooker and Mr. James Harwood examined.

Mr. O. Brooker and Mr. J. Harwood.

973. (*Chairman to Mr. Brooker.*) You are now employed at Portsmouth?—I am.

974. (*To Mr. Harwood.*) So are you, I believe?—Yes.

975. (*To Mr. Brooker.*) You were formerly inspector of coal for the Admiralty in the Northumberland and Durham district, were you not?—Yes.

Mr. O. Brooker and Mr. J. Harwood.

15 June 1875.

976. How many years were you inspector there?—Nearly four years.

977. Do you remember how much coal passed under your eye during the time you shipped for the Admiralty?—I suppose about 50,000 tons.

978. During that time, were there any cases of spontaneous combustion of the coal so shipped?—Not at the port.

979. But after the ship left port?—Yes, I heard two years afterwards that spontaneous combustion had taken place in one case; I fancy it was at Jamaica.

980. In one single case?—Yes.

981. You only know of one case of spontaneous combustion in all the coal shipped from the north during those four years from 1864 to 1868?—One case only of government coal.

982. Were the particulars of that case referred to you for report?—Yes, and on examining my book I found I had inspected but very little of the cargo in consequence of my having other ships to inspect.

983. Do you remember what coal it was?—No, but I think it was shipped in 1865.

984. You ceased to hold that office in 1868?—Yes, early in 1868.

985. Does your recollection go to any other circumstance connected with that case of spontaneous combustion?—No, only that the report from that station was that the bulk of the cargo was small and contained pyrites.

986. All that you remember about it is that it was at Jamaica?—I think it was at Jamaica. I know it was at some hot station.

987. Beyond that, what the coal was, or how it was shipped, or as to any of the circumstances of the casualty, you have no recollection?—No, I was not present when it was shipped.

988. Were your instructions to avoid any particular classes of coal as liable to spontaneous combustion?—I had no instructions to that effect; my instructions were to receive what was considered first class coal.

989. The question of the liability of coal to spontaneous combustion was not one which came prominently under your notice?—No.

990. Was not it included in the Admiralty instructions at all?—No, at least I never received any instructions upon spontaneous combustion.

991. So far as the shipment of coal under your responsibility is concerned you cannot give the Commission much information as regards spontaneous combustion?—I objected, and complained if brassy coal were permitted to pass into the waggons or ships. I had a suspicion that if I were not present that this coal would be passed; that they would not be so particular about it.

992. You were specially there to prevent coal with sulphur in it from being shipped?—My instructions were that the coal were to be fresh raised and properly screened from dust. I occasionally went to the pits to see if they were so; the people at the colliery not being aware of my intended visit. When I found that in the case of this particular cargo there had been spontaneous combustion, I was inclined to think that it was in consequence of my not being there to inspect

993. That is to say that they had taken advantage of your being overworked to ship a considerable quantity of brassy coal?—That was a thing I could not prove.

994. Was that the only cargo you had not the opportunity of inspecting?—Yes; there would be several cargoes that I could only inspect one-third or perhaps two-thirds of, but I do not know there was any other entire cargo, that I did not inspect.

995. Were you supposed to see every ton of coal that went into the ship's hold?—If I possibly could.

996. We understand that you and Mr. Harwood can give us some information as to the storage of coal at Portsmouth. How is coal stored there?—The coals are stacked into heaps about the dockyard and exposed to all weathers; in other places they are under cover.

997. Is there any coal afloat also?—Yes, there is coal afloat in the hulks.

998. What sort of quantity is usually exposed to the weather on shore?—Probably 7 or 8 thousand tons; at the present time there is not so much, but a year ago there was a very large quantity in the dockyard.

999. How much coal do the coal hulks hold when full?—I think they hold about 2,000 tons each.

1000. Have you had any cases of coal heating in the dockyard or in the hulks?—No, I never heard of any.

1001. Though a large quantity of coal is constantly exposed to the weather?—Yes.

1002. Is there much small in the coal?—There is a very large quantity sometimes.

1003. And you have never had a case of heating?—I have never heard of any case of heating.

1004. (*To Mr. Harwood.*) Have you ever had any cases?—I have had one case of heating.

1005. Will you tell us the circumstances of that case?—When I was at Jamaica at the Port Royal Dockyard, we had a case of heating. There is a large coal store there.

1006. How did that arise?—I think it occurred from the coals getting wet on being taken ashore, and from their lying in the store; they were lying in the store for two months I should think; the name of the coal was, I think, Parsons Abbey Graigola.

1007. In what year was that?—In 1864.

1008. Did that coal visibly contain a large amount of pyrites?—I did not observe more than usual.

1009. You could not detect the presence of an undue quantity of pyrites?—No.

1010. That is the only case that has come within your knowledge of spontaneous combustion of coal?—Yes, that is the only case I know of.

1011. What did you do in that case?—I had the coals taken out of the store, and when it was replaced, I put iron tubes into it of various lengths suspended from the beams in the roof. I found that these tubes carried off all the gas. I always adopted that plan afterwards, and there was no more heating.

1012. You never heard of any case of dangerous heating in that store since?—No. It was a very large store.

1013. (*Mr. Cory to Mr. Brooker.*) When you were inspecting in the north, and were not able, as you say, to see the shipment of every cargo, were you absent at long intervals from a particular place, could your absence be calculated on?—I do not know that they could calculate on my absence; perhaps I would go to Sunderland, then to Tyne docks, and then to another place probably.

1014. As to this brassy coal which you suppose to have been shipped behind your back whenever you were absent, where did it come from?—I do not know, I cannot recollect it being got 10 years ago.

1015. If this brassy coal could be shipped during the interval of your absence, surely it must have been lying in the neighbourhood already?—No; because it comes five or six miles by train; to the mouth of the pit it would be five or six miles.

1016. Were they steam coals?—They were steam coals.

1017. Newcastle coals?—Newcastle coals.

1018. Were they Hartley coals?—Some description of Hartley coals.

1019. Would not they have to come 20 or more miles to the shipping place?—Not so much as that, I think.

1020. Did the coal come down the Blyth and Tyne railway?—I am not certain about that.

1021. You do not know that the coals come from the north of Blyth, 20 miles off?—No, I do not.

1022. You really think that these coal owners, or their agents, were laying by this brassy coal to put on board when your back was turned?—No, I do not say that, but it seemed to me strange that that should be the only cargo taking fire I could not inspect.

1023. You only know of one cargo being on fire?—That is all.

1024. And it happened that in that case you did

Mr. O. Brooker and Mr. J. Harwood.

15 June 1875.

not very closely inspect the coals ?—I was not able to inspect them.

1025. Do you draw from that the conclusion that whenever your back was turned brassy coals would be put on board ?—No, I have not said that, but I conclude that they would not be so careful.

1026. (*Mr. Fenwick.*) You say that there are occasionally 2,000 tons stored in the hulks ; is there any means taken to ventilate those hulks ?—I do not know of any

1027. (*Mr. Icely.*) Are you in favour of ventilating coal cargoes?—Yes.

1028. For what reason ?—I think that by ventilating the coal you get rid of the gases ; which may be done by putting tubes into the centre part of the cargo. I know this, in my own case, that in the "Crocodile" Indian troop ship the temperature of the coals near the boilers would rise to 136°, and by opening our outside ports the temperature would be lowered.

1029. Are you speaking now of the coals that were in the bunkers at the back of the boilers ?—Yes, at other parts of the bunkers the temperature would be about 80° or 90°. I am speaking of when we were in the Red Sea.

1030. What year are you speaking of ?—1871.

1031. You were in the Crocodile for some time ?—Yes, for $4\frac{1}{2}$ years.

1032. For what period ?—From 1868 to 1872.

1033. During that time had you any cases of heating of coal ?—None whatever.

1034. This heating up to 136° you attributed to the heat of the boilers ?—Yes.

1035. Do you suppose that eventually spontaneous ignition might have resulted from that heat unless you had taken steps to promote ventilation ?—Yes, and I began to work upon that coal immediately. I made use of it at once.

1036. Will you describe the custom on board ship with regard to ascertaining symptoms of approaching danger ?—All coal boxes are fitted with temperature tubes, and every four hours the thermometer is put down in the tube, and is allowed to remain for 20 minutes and then taken up to see what the temperature is. Where there is danger it is done every half hour. The temperature tube plugged at the bottom and partly filled with water gave, it seemed to me, a quicker indication of the heat.

1037. Did you notice in this particular case when the temperature rose to 136° that the temperature rose rapidly ?—No, it rose gradually ; it rose as the weather got warmer.

1038. What would be the ordinary temperature when you commenced to take it ?—About 90°.

1039. What period elapsed between the time when you found it was 90° and the time when it rose to 136° ?—Two or three days.

1040. And it was still increasing ?—No, it remained stationary there for three or four days till we got out of the Red Sea.

1041. You do not apprehend that it would have risen any higher ?—No ; at first I was rather uneasy, but on the second trip when it came to that temperature and did not go beyond, I did not apprehend any danger.

1042. Are you of opinion that the opening of those ports was sufficient as a means of ventilation ?—Yes, that was my opinion, the air entering from the bunker doors when raised caused a circulation.

1043. Do not you think a circulation of air would be better ; do not you think an inlet as well as an outlet would be more advantageous ?—Yes I do ; an outlet either into the steam funnel or the galley funnel would cause a draught.

1044. That would induce an active current ?—Yes.

1045. In the "Crocodile" your coal boxes were in compartments, were they not ?—Yes, seven compartments.

1046. And you had watertight doors ?—Yes, two to some compartments and one to others.

1047. In fact you hermetically sealed your coal boxes when the bunker lids were on ?—Just so, and the bunker lids were made like a joint to keep out the water lying on the decks.

1048. Do not you think there is greater chance of fire or spontaneous combustion where the bunkers are hermetically sealed, as it were, than there would be in the ordinary case of an old ship where the bunkers are not isolated in that way ?—I certainly do. I never knew of any case of gas explosion in the many wooden ships I have served in.

1049. Do you think it advisable that in the bunkers of those iron-clad ships there should be a means of ventilation ?—Yes, I do, by means of tubes placed in a zigzag direction, so that the coal may be more fully penetrated with ventilation.

1050. (*Mr. Duncan.*) Have you any impression in reference to the effect of shipping coals wet ?—I have no practical experience as to that, but I should imagine that coal with a large amount of small in it, when shipped wet, and especially when not well handpicked at the pits, would cause spontaneous combustion.

1051. For what reason ?—I cannot give you any other reason than that which is usually assigned.

1052. You cannot say from any chemical or scientific investigation that the application of water to pyrites would be likely to cause combustion ?—No.

1053. In the 150,000 tons of coal you saw shipped, many of the cargoes went on board wet, I suppose ?—Some of them were so.

1054. You did not object to their being shipped in rainy weather ?—No ; other ships were waiting to be loaded, and if I had detained a cargo, there would probably have been some "demurrage."

1055. You objected to them if you saw indications of sulphur on their surface ?—Yes.

1056. That would have the effect of causing the people at the colliery who were sending down coal for the use of the Admiralty to be careful not to send down waggons of coal that had such indications in them ?—Yes.

1057. Have you sent back coal which possessed such indications ?—No ; but I have always cautioned the colliery agents that I should do so. I may say that the coals I saw were very fair indeed. The difficulty I had to contend with was the small coal. I visited the pits to see what screens they were using.

1058. It is hardly a fair inference, is it, that because you happened to be away, in the case to which you have referred, they sent in sulphurous coals ?—The impression I had then was that this coal would not have been passed by me.

1059. Have you seen them shipping sulphurous coals to any other vessels when you have been inspecting coals shipped for Admiralty use ?—I have certainly seen some things going on, but it was no business of mine, that is to say, those things did not occur in connexion with the coals I was inspecting.

1060. Have you seen coals being shipped on board other vessels for private use that you would not have taken for the Admiralty ?—Certainly I have.

1061. In consequence of their containing apparently a large quantity of pyrites ?—Yes, and I have seen water thrown upon the coal, and when I have asked them what they did that for they would say to lay the dust. I thought it was to increase the weight.

1062. While you were inspecting coals for the Admiralty you must have seen many other shipments of coal for private use ; in your judgment, were there more sulphurous coals among those than among those shipped for the Admiralty ?—Coal under no inspection is not so well shipped, nor of such good quality, nor such large coal as that which is shipped under inspection. I have seen coals shipped in such a careless way that if they had been large they would soon have been reduced very much in size.

1063. When coals are wrought from the bowels of the earth, have they frequently evident indications on their surface that there is a large quantity of pyrites or sulphur in them ?—I have not seen much of it in

Mr. O. Brooker and Mr. J. Harwood.

15 June 1875.

the coal I have inspected; I know there are pyrites in all coal.

1064. Are you aware that the miners when they come upon it know it perfectly?—Yes.

1065. And that they would put it on one side if they were desirous of keeping it out of the coals they were shipping?—I know that coal containing pyrites will come down for shipment in spite of all precautions. When I have been at the pits I have seen two boys probably at each screen hand-picking the coals, and still I know there was a difficulty even then in keeping out the sulphurous coals, because while I have been watching the boys picking out the coals I have said "Here is one piece you have let slip by." I know they were very particular while I was there.

1066. You know there are coals with large quantities of iron pyrites in them which are picked out by the coal shipper?—Yes, the coal is supposed to be hand-picked.

1067. Do you think it probable that the more frequent occurrence of cases of spontaneous combustion during the time that coals were dear was due to the fact that they were not so particular to hand-pick those pyritic pieces?—Very likely it was partly due to that.

1068. (*Sir G. Elliot.*) You say you were stationed on the Tyne?—Yes, at the northern ports.

1069. You would be at the ship at the time the coals were shipped?—Yes, the greatest part of my time would be at the place of shipment.

1070. Had you any written instructions as to your inspection?—Yes.

1071. Have you a copy of them with you?—No.

1072. Do you remember what they were?—I was to see that the coals were not small, to be fresh wrought, and properly shipped. They were to pass over half-inch screens.

1073. Were you directed to take care that there should be nothing in the coals that would lead to spontaneous combustion?—I think not. I do not remember anything to that effect.

1074. The main thing you would pay attention to as inspector would be to see that the coals were large and as free from small as possible?—Yes, that would be one of the principal things.

1075. And that they were put into the ship with as little breakage as possible?—Yes, and this had to be equally well watched.

1076. That would be about the extent of your duty as inspector?—Yes.

1077. You attention had not been directed so much to the spontaneous combustion of coals on board ship at that time?—No.

1078. (*Chairman.*) When you said you rejected coal that looked as if it had much sulphur in it, did you do it on your own motion or under instructions?—When I found coal having those indications I made a complaint.

1079. (*Sir G. Elliot*). You mean this; you saw something go in which had certain appearances which caused you to reject it, but you did not reject it because you thought it would be likely to ignite spontaneously?—I knew that sulphurous coal would be liable to cause spontaneous combustion.

1080. You had no direction about it?—No.

1081. Therefore whether it had been a piece of stone or a piece of pyrites you would have objected to one as much as the other?—I would have objected to the stone as well as the pyrites, because my duty was was to see that coal shipped.

1082. You saw a great many stones go in as well as pyrites?—Not many. Not enough to cause any complaint to be made by me.

1083. One part of your instructions was to see that the coals were sent away free from small. Was not there also an instruction that they were to be clean?—Yes. You could not expect coal after travelling 10 or 15 miles to arrive at the ships without some dust in the coal.

1084. You said that coals that were shipped under inspection were larger and better than those which were shipped without inspection. Do you suppose the viewer at the colliery, who has the charge of the production of the coal, knows when he is drawing coals out of the pit and putting them into the truck, whether there is a ship at the drops for the Admiralty, or a ship for the Austrian Lloyds, or for any other large company who have no inspectors? Do you suppose they know the difference at the colliery?—I know I went into one pit, and found that the screens were not according to the Admiralty width; that is some of the screens were three-eighths instead of half an inch. I objected to the Government coal passing over those screens, and they did not allow them to pass over the three-eighths screens. The ship to which those coals were going was the "Constance," and the trucks were marked "Constance." They must have known that the coals were being shipped for the Government, because they always got intelligence from the agent at the docks that the coal was for the Government, and there was more care taken in consequence.

1085. You were not often at the colliery, were you?—Not often, but as often as I could be.

1086. What colliery was that to which you refer?—The Hastings Hartley.

1087. Do you know what quantity they raise in a day?—Yes, I believe I do.

1088. 1,000 or 1,500 tons a day?—Yes; and it is one of the best coals too.

1089. Do you think they know when each ship goes under the drops, and that they regulate their screens to suit it?—I saw that they were passing the coal over some three-eighths screen, and on my calling attention to it they passed the coal over the half-inch screens.

1090. You say you would not often go to the colliery to see how it was done?—No; I would go about once a month to the different collieries.

1091. How many collieries were you supplied from?—I suppose, roughly speaking, about a dozen.

1092. You would get to each colliery once in 12 months?—No; I would take one here and there, oftener seeing those I took the most coal from.

1093. Your inspection of what they did in loading could not have been very minute?—Not at the pits, as my visits were few; but as I said before, coals under inspection were better in every respect.

1094. When you were looking at them they took more care than when they were not being looked at?—Yes, that was the case.

1095. How many tons out of those 150,000 tons did you see shipped?—I dare say I saw 35,000 tons of them shipped.

1096. You had not much time to go to the collieries?—No.

The witness withdrew.

Mr. W. Covey and Mr. R. Moore.

Mr. William Covey and Mr. Robert Moore examined.

1097. (*Chairman to Mr. Covey.*) You are chief inspector of machinery?—I am.

1098. (*To Mr. Moore.*) You are chief engineer?—Yes.

1099. (*To Mr. Covey.*) You have charge of the steam reserve?—Yes.

1100. You can give the Commission some information as to the storage of coal at Devonport, can you not? how is the coal stored?—Some of it is housed, and some is not.

1101. Is any afloat?—Not at Devonport only what is kept in small hulks.

1102. All your experience, therefore, of storage at Devonport is storage on shore?—Storage on shore.

1103. How much coal is usually in stock there?—I could not say, as I have no charge of coals in the dockyard; I do not know.

1104. (*To Mr. Moore.*) Can you say?—I have no idea at all.

1105. (*To Mr. Covey.*) Can you give us any infor-

Mr. W. Covey and Mr. R. Moore.

15 June 1875.

mation as to any heating of coal in store either at Portsmouth or elsewhere?—I have never seen any heating of coal.

1106. (*To Mr. Moore.*) Have you seen any heating of coal?—No.

1107. (*To Mr. Covey.*) Have you seen any heating of coal afloat?—No, not heating. I have never seen any heating in any case.

1108. (*To Mr. Moore.*) Have you any information to give us upon the subject?—I was in a ship on one occasion when we had spontaneous combustion in the coal bunkers.

1109. What ship was that?—The "Gladiator." That was 29 years ago.

1110. (*Mr. Fenwick to Mr. Covey.*) Is the mode of ventilation now different from what it was eight or nine years ago?—In some respects. Pipes are carried away from the bunkers into the funnel casing, and also ventilators are put on the top of the coal bunkers to ventilate them.

1111. Is it desirable that there should be ventilators in the bunkers?—I think so.

1112. Do you know whether fewer cases of heating have taken place since ventilators have been put in the bunkers?—That has come under my notice. Why I think ventilation is necessary is because I have never seen any heating, but I have seen an explosion of gas.

1113. (*Chairman.*) Can you give us any information about that case of explosion?—It occurred in the "Agincourt" about two years ago.

1114. Do you know what coal it was?—No; I cannot remember with certainty the name of the coal; it was a mixed coal.

1115. Had it been long in the bunkers?—No.

1116. Had the lids been kept on some time before the explosion?—No; they were taken off at the regular times.

1117. You do not remember any circumstance connected with the explosion which would be of interest to us?—No more than that. I think in all vessels where there are tank boxes, ventilation is required to allow the gas to escape.

1118. Was there no special ventilation in the "Agincourt?"—There were small valves on the top of the boxes.

1119. Has any order been given, or has any change been made since that explosion in the "Agincourt?"—An order has been given that coal boxes are to be ventilated.

1120. Does that apply to the whole service?—Yes.

1121. Was that the result of that explosion on the "Agincourt"?—Not at all.

1122. Was that one case out of many?—I saw that one and there was a case of explosion on the "Devastation" while I was there.

1123. Do you think that it was in consequence of those cases that that order was given?—Partly.

1124. (*Sir G. Elliot.*) Do you know whether the ventilation of the ship is wholly self-acting or is it promoted by some mechanical appliance?—It is not promoted by any mechanical appliance, it is self-acting.

1125. Do you know whether such self-acting ventilation is sufficient in itself to keep the ship free from the accumulation of gas?—I think it would be sufficient. I have not actually seen the cases, but when the bunker lids have been on more than two or three days there has been an explosion whereas if they had been taken off every day such a thing would not have occurred.

1126. Do they go into the coal bunker with safety lamps?—They have safety lamps in working the coal boxes, they always use safety lamps.

1127. How is the explosion caused if they use safety lamps?—They would not have an explosion if they used them; but in this case, it being rather dark, the man took a light, though he ought not to have done so.

1128. So far as your experience goes, it is more limited to explosion rather than spontaneous combustion?—Yes, I have never seen any spontaneous combustion in any ships.

1129. What quantity of coal do you receive into the stores under your control, what is the largest quantity you have had at any given time in that depôt on shore, would you say 10,000 tons?—I should think there would be that quantity. I have no control or charge of coal in the dockyard; one building is three tiers high, others one; some coals have no covering.

1130. Are they all in contact?—There is a separation, a floor between.

1131. They are not more perhaps than 15 feet apart?—They are only divided by the flooring.

1132. The distance between the floors would not be more than 15 feet?—It would be quite that, it would be 20 feet.

1133. Would it make any difference, supposing instead of having those separate floors the coals were stored in one mass; would it have any effect in producing spontaneous combustion?—I should think so.

1134. However, by your appliances you never have had even heating; have you ever tried the temperature?—No, I have never had anything to do with applying tests in the store.

1135. Is there any opinion or theory amongst you gentlemen who talk about these accidents by spontaneous combustion, as to the cause of it; do you attribute it to any particular cause?—No, I have rarely heard of spontaneous combustion myself. I have heard of explosions. I have never known of any cases of explosion in wooden ships, where there is more likely to be an admission of air from their not being so perfectly tight.

The witness withdrew.

Adjourned to Tuesday next at 12 o'clock.

Tuesday, 22nd June 1875.

PRESENT:

THE RIGHT HON. HUGH C. E. CHILDERS, M.P. IN THE CHAIR.

Sir GEORGE ELLIOT, Bart., M.P.
HENRY HUSSEY VIVIAN, Esq., M.P.
FREDERICK AUGUSTUS ABEL, Esq., F.R.S.
RICHARD CORY, Esq.
GEORGE DUNCAN, Esq.
JOHN FENWICK, Esq.
JOHN FERGUSON, Esq.
CHARLES ICELY, Esq.
JOHN PERCY, Esq., M.D., F.R.S.
WILLIAM YOUNG, Esq.

J. M. CARMICHAEL, Esq., Secretary.

Mr. W. R. PRICE examined.

Mr. W. R. Price.

22 June 1875.

1136. (*Chairman.*) You are a shipowner in London?—Yes.

1137. I believe you have had experience of more than one case of spontaneous combustion in ships belonging to your firm?—Yes, two cases.

1138. Both, if I am not mistaken, were cases of coal

Mr. W. R. Price.

2 June 1875.

shipped from North Shields ?—Yes, in the Northumberland dock.

1139. They were both in the same month ?—Yes.

1140. The shipments in both cases were for the Peninsular and Oriental Company ?—Yes.

1141. Will you inform the Commission what the size of the cargoes was ?—Yes. The cargo of one of them, namely, the Calcutta, was 1,870 tons, to the best of my recollection, and the cargo of the other 1,600 tons ; the respective tonnage of the ships being 1,372 and 1,112 tons.

1142. They were both practically full ships ?—Yes.

1143. What were the names of the ships ?—The name of the 1,372 tons ship was the "Calcutta," the name of the 1,112 tons ship was the "Oliver Cromwell."

1144. Were they both wooden ships ?—Yes.

1145. Will you state what the character of the coal was ?—I did not see the bill of lading, but I believe it was Howard's West Hartley, I was told that was the coal.

1146. Were both cargoes shipped in the summer of 1874 ?—In June and July 1874.

1147. What was the ventilation adopted in the ships ?—I am relying on what I heard from my overlooker in the matter entirely ; the ventilation was a horizontal shaft near the bottom of the ship, from the keelson to the skin of the ship, boarded in, making a triangular current right through this communicating with two lines (about 18 inches square) of tunnelling along the tops of the 'tween deck beams, these being connected with upright shafts in each hatchway.

1148. Were the upright ventilators the one upwards and the other downwards ?—No, at least I imagine they would be self-acting.

1149. Do you know how the coal was put on board, was it by tips ?—From tips in both cases.

1150. Do you know from what height the coal fell ?—I could not state the number of feet. I was there when the Oliver Cromwell was under the tip, and it struck me as a very considerable height ; I do not know what the state of the tide was when I was there, whether the water is higher or lower at various states of the tide I do not know, but the fall was considerable.

1151. When you were there was the coal much broken in the fall ?—Very much indeed. I went into the hold of the "Oliver Cromwell" when she was about half loaded, and I noticed in the main hatchway where the bulk of the cargo was coming down a great accumulation of small coal in a pyrimidical shape, and I said to the captain as I came up, "I am thankful that "I am not the owner of this cargo, there seems to be "so much small in it."

1152. Can you give the Commission any information as to the nature of the casualty in the case of the "Oliver Cromwell," where and how it was observed, and what the result was ?—I took all the trouble I could to elicit the information, but the only parties who came home from the "Oliver Cromwell" were the captain and an apprentice ; the rest of the crew were paid off at the Cape and took other employments. Their information did not quite correspond, but at various times I had conversations with them, and the apprentice gave me to understand that there was no indication of anything wrong either in the fore or after peak of the ship where he was frequently down for various purposes. He never detected any escape of gas or anything of that sort, but he said that a fortnight before the fire broke out he noticed vapour coming up the main hatch ventilation, and he said as you passed between it and the wind, there was an unpleasant smoky smell, but they evidently treated it as nothing more than was usual in coal ships. I asked him whether they were not alarmed, he said not at all, and it was only the day before they had to abandon the ship, that the fire broke out and they noticed it by smoke oozing through the upper planking of the ship.

1153. Not coming up through the ventilators ?—Not coming up through the ventilators.

1154. How long had the ship been out ?—She sailed on the 18th of June and was burnt on the 6th of September.

1155. Did she become a total loss ?—She became a total loss.

1156. Was there any Board of Trade inquiry ?—There was an inquiry at the Cape.

1157. Do you remember what the result of the inquiry was ?—I remember that the general result was considered an unavoidable casualty.

1158. There was no scientific inquiry ?—No.

1159. That was the case of the "Oliver Cromwell" ?—Yes.

1160. Now will you give us the particulars of the other case ?—In the case of the "Calcutta" she sailed on the 2nd of July, and was burned on the 17th of September.

1161. In about the same place ?—A little wide of the same locality, but pretty much in the same region.

1162. Was she a total loss ?—She was a total loss, with a very heavy loss of life.

1163. What were the circumstances as reported to you about that ?—The few men that arrived at home were about as stupid a lot as I ever met with ; there was only one intelligent man among them.

1164. Was the captain lost ?—The captain was lost, he, a little boy of his, the chief officer, the carpenter, and several of the men ; 12 in all had the biggest boat, the others were in two other boats. It came on to blow the night after they left the vessel and the boats separated, and they never saw anything of the captain and his boat ; the others were picked up by a passing vessel.

1165. What information did they give you as regards the fire ?—They said they had no indication of the fire till it had gained considerable power, and a few hours afterwards they were obliged to abandon the ship.

1166. How did they notice it first ?—By smoke coming up the hatchway, and they immediately dug down into the coal and they got some distance below the line of 'tween deck beams, below the main hatchway, and then the heat was so intense and the smoke so suffocating that they were obliged to leave it. They poured down water and so on but without any effect ; it had gained a considerable hold of the cargo for almost immediately the masts fell over the side; they were iron masts. The water in the pump well with the intense heat at the bottom of the pump generated steam and blew all the pumping apparatus right out.

1167. Was she ventilated in the same way as the "Oliver Cromwell" ?—Exactly in the same way.

1168. Do you attribute the fire to any peculiarity of the coal ? Was any other coal of the same denomination shipped about the same time ?—In giving an opinion upon that it is simply my own individual opinion, I have no scientific knowledge upon the subject, but as far as I can reason upon the subject I attribute the loss to some inherent quality in the coals as in the other case.

1169. Was there any other ship loading with the same coal ?—The "Euxine" was loading in the dock at the same time ; she was an iron ship belonging to Messrs. Bates of Liverpool ; she was also burned.

1170. (*Sir George Elliot.*) Was the coal in each case from the same colliery ?—I think so. I could not positively say it was coal from the same colliery in the case of the "Euxine."

1171. (*Chairman.*) Were the coals loaded in the same dock ?—Yes.

1172. And probably in the same way ?—Exactly in the same way.

1173. And that vessel was lost about the same time as the others ?—A few days before the others ; she had not got quite so far. There was a curious fact connected with it that a ship called the "Corah," a large American ship, was loading about the same time. She was an American wooden vessel and the captain demurred to ventilation altogether. The Peninsula and Oriental Company coal inspector had some conversation with him upon the subject, as I gather from a report made by him to his directors, and the

Mr.
W. R. Price.
——
22 June 1875.

captain of the "Corah" said that he did not hold with ventilation except above the cargo, for instance, under the 'tween decks and under the main deck; that as to through ventilation he did not hold with it, but he said if the inspector insisted upon it he must do it; he said he had no instructions to insist upon his doing it, and so he left the captain to do as he liked.

1174. What was the result?—She arrived out at Bombay apparently without accident so far as I can see from the lists.

1175. I believe you have had great experience in shipping coal?—For the last 17 years I have scarcely carried anything else as outward cargoes to Bombay.

1176. Especially for the Peninsula and Oriental?—And for the Great Indian Peninsula Railway Company, and sometimes on our own account.

1177. So you can speak on the matter with very considerable experience?—Certainly; but not with regard to the Tyne, those were the only two cargoes I ever carried from the Tyne.

1178. Where have you carried principally from?—From Birkenhead in all cases, except patent fuel from Cardiff occasionally.

1179. Have you ever had any casualties in ships sailing from Birkenhead or Cardiff?—Never.

1180. Is the manner of putting the coal on board different in Birkenhead from what it is in the Tyne?—There are two modes of loading cargoes at Birkenhead; one is by tips similar to the mode of loading at the Tyne, and the other is by barrows. The railway runs alongside the dock and the railway wagons are brought alongside the ships, and when they are loading by barrows a stage is made right over the main hold; the coal is shovelled into barrows and wheeled over the hatchway; then the tackle is fastened to the barrow and it is lowered on to a platform in the hold, and it is then wheeled to the spot where it is wanted.

1181. In your opinion is that method preferable not only in reference to its doing less damage to the coal, but with reference to the subject of our inquiry?—Unquestionably that is my opinion.

1182. You think the distance that coal ought to fall should be a minimum?—I think there is less breakage, and consequently a better natural ventilation through the cargo; it does not lie in such a dense mass.

1183. You would recommend that all coal should be shipped in that way?—I put it this way; that in all cases I should stipulate for it where I could. I am bound to say that shipowners cannot command everything; but if I could, I would never ship a cargo otherwise than in that manner.

1184. With reference to ventilation, you have told us what the captain of the "Corah" thought about it. Have you formed any judgment upon the question?—I certainly have come to this conclusion, that if I were obliged to carry coal from the Tyne, I should certainly not adopt any other mode of ventilation than that which for 17 years I have successfully adopted in the case of vessels going from Birkenhead.

1185. With reference to your shipment from Birkenhead, what plan of ventilation have you adopted?—Exactly the same as I adopted in the Tyne; it has always been successful in the case of vessels going from Birkenhead; but it was fatal to me in the case of the vessels going from the Tyne.

1186. Your experience of the Tyne is limited to those two cases?—Yes; but there was the "Euxine" which was loading at the time.

1187. Was she lost also?—She was lost also.

1188. May that not have been from the coal in each case being supplied from one particular seam?—It may have been; I can call to mind several other vessels, one of them the "Bernice," that came from Dundee to the Tyne, she also was burnt close to Bombay, having on board Tyne coal. I could not say whether it was from the same seam. I have noticed more burnings in the case of vessels from the Tyne than I have from any other place.

1189. Are you aware that a good deal of the north country coal is shipped very much upon the plan you have described as being the one you prefer?—No, I am not aware of that; I never was on the Tyne except on the occasion when I had those two ships loading there.

1190. And when you were so unfortunate as to lose both ships?—Yes.

1191. (*Sir G. Elliot.*) The "Calcutta," you said, sailed on the 2nd July, and she took fire on the 17th of September?—Yes.

1192. How many days was that that she was out?—77 days.

1193. Now with regard to the "Oliver Cromwell," how long was she out?—I think she was out 80 days.

1194. Your two vessels, the "Oliver Cromwell" and the "Calcutta," both loaded Howard's West Hartley, did not they?—Yes; I have not seen the bills of lading. Directly I heard of the casualty to the "Oliver Cromwell," I went to the brokers office to ask what coal she had on board, and the message that came back was Howard's West Hartley.

1195. That was one of the vessels?—Yes, they were both chartered by the same parties.

1196. The "Calcutta" you say, was a total loss?—Yes, and the "Oliver Cromwell" was a total loss also. There were lives lost in the case of the "Calcutta."

1197. Then you said that the "Euxine" was loading at the same time, and that she also took fire?—Yes; she took fire a little earlier. I remember being in Liverpool and hearing an account of the loss, and it made me wonder how my ships stood, they having been loaded about the same time; it might have been in the early part of August that she took fire.

1198. Do you know what coal the "Euxine" took in?—I believe it was the same coal; I am speaking from impression; the parties would be very chary in giving me information about it.

1199. Then you mentioned the "Corah," and you said that she was loaded about the same time?—She was in the Northumberland Dock at the same time.

1200. The arrangements for the ventilation of the cargo in her case were dispensed with, and she arrived safely?—Yes.

1201. The other three vessels adopted the system of ventilation which you have practised for many years at Birkenhead?—I believe so; I am corroborated in that opinion by a report of the Peninsular and Oriental Inspector Mr. Steinson, in which he says, that he believes that they were so ventilated.

1202. (*Chairman.*) Will you read that report?—He says:—"November 1874. To the Managing Directors of the Peninsular and Oriental Steam Navigation Company, London. Gentlemen, I beg to acknowledge receipt of your letter of 2nd inst. respecting the burning of the 'Calcutta,' loaded with Howard's West Hartley, at sea, and referring also to the burning of the 'Euxine' and 'Oliver 'Cromwell,' with the same coal, and requesting me to institute careful inquiry into this matter, and as to the liability of this coal to spontaneous combustion. In reply, I beg to state that the 'Calcutta' and 'Oliver Cromwell' were both single decked wooden ships, and were well ventilated; the 'Euxine' was a double-decked iron ship, and I think also well ventilated. In looking over my journal I find these ships were all loaded in fine weather, that the coal looked very well, and the only remarks about these cargoes were that the ships were too high for the accommodation, and the coals consequently much broken in shipment. The 'Cora,' American ship, was loaded at the same time as the 'Calcutta,' and with the same coal; this ship was double decked, but the captain, who was a man of great experience, objected to through ventilation, but said, if I insisted on the ship being ventilated, he would do so, though he would rather not. I said I had no instructions as to ventilation, and my opinion was that it was unnecessary, and was dangerous in many cases, this ship was therefore not ventilated through the coal, but was well ventilated above it, and I find in my journal that a portion of this cargo got wet with hail and rain, and was thus more liable to heat. As

Mr.
. Price.
ne 1875.

“ to the necessity of ventilation in cargoes of north country steam coals, and the mode of ventilating, I may state I have been giving this subject much consideration for years, and more especially of late, when so many ships are reported as having been burned at sea by the spontaneous combustion of their cargoes, and to the fact that, so far as I know, all the ships which have been burned have been well ventilated, or what is considered good ventilation, viz., vertical shafts in each hatchway, connected at the bottom either with a platform under the coal, or with other shafts running fore and aft under the coal alongside the keelsons or sometimes vertical shafts only in each hatchway, whereas ships belonging to the north, as a rule, have no through ventilation, and they very rarely take fire. My opinion is that north-country steam coal, under ordinary circumstances, does not require through ventilation, but that it is actually safer without it for the following reasons, viz.—1st. The coal does not contain sufficient gas to require any through ventilation; 2nd. The coal when well cleaned does not contain in itself anything to cause spontaneous combustion; but if any pyrites should have been overlooked in the cleansing, and is then subjected to a heavy weight of coal passing on it, it is liable to heat, and if a current of air can get at it from the through ventilators, it might then ignite, and probably set the whole cargo in a blaze, which would be effectually fanned from the ventilators, and the ventilators themselves being usually made of dry soft wood would probably be the first thing to ignite. I would suggest that the ships should be well ventilated above the coal only, that as many ventilators through the deck-houses as can be conveniently fitted be well attended to, and that on all possible opportunities the hatches should be kept open. I submitted my reasons and my proposed mode of ventilation to my friend the practical chemist before sending them to you, and I have not altered one word of my original copy. He said what I stated is a great chemical fact, and not to be disputed, and that the most effectual way to set a ship on fire with the north-country steam coal is to put in through ventilators, as it is scarcely possible to avoid pyrites among the coal to a greater or less extent. As to Howard's West Hartley being peculiarly liable to spontaneous combustion, I am unable to say. So many ships being burned at one time looks suspicious; but then ships with other coal have been burned at the same time—the ‘Pocohontas’ with Hasting's Hartley, the ‘Susannah Johanna’ with Carr's Hartley, ships from Cardiff, from Liverpool, from the Clyde, from Dundee, and ships with general cargoes. It looks like an epidemic; and I fear the reason will have to be discovered from other causes than from spontaneous combustion. For many years very many ships, and many of large size, have loaded this coal for the company's Indian ports, and carried it safely. I would respectfully suggest that this question be submitted to some eminent practical chemist or other authority for confirmation.”

1203. (*Sir G. Elliot.*) You were speaking about the improved mode of loading the cargo by barrows with a ship like yours of 1,800 tons, would not it occupy a long time to load it in that way?—It does require a longer time, and costs more money.

1204. How long would it take to load an 1,800 tons ship?—The loading is not continuous. I do not know how long it would take to load an 1,800 tons ship; sometimes you have a great pressure of coal from the pits, and then you can have the three hatchways going; on other days you have only one hatch working, and so forth. I do not know how much they can load by barrows in a day.

1205. (*Mr. Duncan.*) You could load in about a week?—Yes, if you put plenty of hands on you could load 250 tons a day.

1206. (*Chairman.*) Loading at all the three hatchways?—Yes.

1207. (*Sir G. Elliot.*) Take Cardiff and other ports where coals are loaded; suppose that system were to be adopted, would it not take two or three times the amount of dock space?—At Cardiff the docks are so crowded, and the difficulty of getting your cargo in is so great, that I think it is quite an exceptional place as regards loading.

1208. Take the Northumberland dock; how long were they loading that 1,800 tons ship there?—I do not know; they were some days when they were not doing anything; it was done very quickly when they did get to work.

1209. Is not it a usual thing in the Northumberland Docks for a thousand-ton ship to go in and come out on the same tide?—Yes, I am aware that there is great rapidity in loading, but I think that at times there is a corresponding disadvantage; it may do for coasting voyages, but though there is great facility if you can get your ship under the tips and get her loaded right away, and though there is some saving, I think there are some disadvantages about it for long voyages.

1210. You think where you have long voyages and where the coals have a tendency to spontaneous combustion it might be in some measure guarded against by that more careful mode of packing them as compared with the rapid manner in which they are now loaded?—Unquestionably, of course the capabilites of the place must always be taken into consideration; the coal contractor at Cardiff may have several vessels loading at the same time, and sometimes your vessel may be waiting a fortnight or three weeks for a turn; and he may have three or four other vessels loading at the same time, and he may give you 500 tons a day, then a steamer may come in and you may be hauled out of your berth so that he may fill her up. It is not a question of a vessel going under the tips and getting her cargo right away at once. If they choose they could put 1,800 tons in a vessel in 48 hours. The practical result is that they ship a portion of the cargo very rapidly and then there is a stoppage for some time and that is where time is lost.

1211. If the coal at Cardiff were to be shipped in the manner you mention by barrows, it would take more than three or four times the area for the ships to lin in all the time that they would be detained?—Undoubtedly that would be required. I have loaded vessels on two or three occasions from Birkenhead by tips before I became alive to the advantage of the better mode of loading, and I have never had a heated cargo in a vessel going out of Birkenhead under either system.

1212. You have loaded by both tips and barrows at Birkenhead?—I have.

1213. And you have never had any heated cargoes from either mode of loading?—No.

1214. What is the advantage you attach to loading by barrows so far as Birkenhead is concerned?—Hitherto I have not done it voluntarily, I have done it because it was a stipulation in my charters that that mode of loading should be adopted in future, I shall always adopt it because I think the cargo is more equally distributed, the small coal does not get into a mass in the region of the main hatchway which is the locality where according to my experience fires usually take place.

1215. Your idea is that by shipping the coal as you do by barrows there is a partial ventilation on account of the roundness of the coal?—Yes, it does not get into a dense mass.

1216. Is not that rather against Mr. Steinson's opinion, that he thinks it is safer without any ventilation at all?—No, I think it corresponds rather with his theory of ventilation above the cargo, there is a great amount of natural ventilation that would give a current of air through. I asked the captain of the "Oliver Cromwell" whether his ventilator acted properly and he said that on several occasions he tested them by taking a piece of paper and tying it by the four corners with a piece of string and putting a pebble or something into it and dropping it down the ventilator, and said when he got it down a certain distance, he would

Mr. W. R. P

22 June 1

let the stone fall out of it, and up would come the string and paper together showing that there was a strong draught through his ventilator.

1217. Those coals would be brought out of a mine at a temperature of about 55° and they would be put into the ship at a temperature of from 50° to 60°, that would be the temperature the coal would go in at; assuming that to be so, you put down those ventilators, you go to sea, and then when you get into the tropics you pass a current of air through this coal containing pyrites, perhaps, that current of air having a temperature of 130° or 140°, is that in your opinion calculated to help to ignite the coal?—I should think so, if the temperature of the atmosphere was much higher than that of the coal it would do so, but my opinion is that it would be very much cooler if you got a current of air than if you got a perfectly still atmosphere. A current going down through a ventilator like that would rather cool it than otherwise. When I have been down in the hold of a ship in the Tropics unless she has been very high out of the water, I have found it much cooler down below than up above.

1218. From your experience of over 17 years in shipping coal at Birkenhead where you have tried the two systems of loading, the one by barrows and the other by tipping, you have never had a single instance of heating?—I am giving my own experience as a shipowner.

1219. As a shipowner you have never gone to the Tyne except in the case of two shipments, and there you found that the mode of ventilation which seems to have been successful in protecting you at Birkenhead failed you in both instances when you carried the Tyne coal?—Quite so.

1220. (*Mr. Duncan.*) I suppose the necessity for shipment by barrows at Birkenhead would arise somewhat from the coals being wrought in much larger lumps than they are in the Tyne?—I imagine it is to ensure them being shipped in as big lumps as possible, to keep the coal in large masses, but I do not think it is a necessity arising from the coal being in large lumps when wrought, it is that the shippers of the coal, the Peninsula and Oriental and the Great Indian Peninsula, like it as much unbroken as possible. Taking it by barrows ensures its being shipped without getting too much broken. Then again I have frequently noticed (and my attention was particularly directed to it) that in loading the coal by barrows great care is taken to pick out every objectionable looking piece. I have seen at the end of a day's work a great pile of brassy looking lumps and slaty pieces all carefully taken out. Whether there is anything dangerous in those brassy looking lumbs I am not prepared to say. I imagine that they pick them out because they are not good to burn.

1221. You have probably seen coals loaded at the Northumberland Dock with an iron skid put down the hatchway to cause the coals to run to the side?—I was only there for a few hours when the ship was loading. I did not notice it particularly.

1222. In your judgment had the weather at the time the coals were shipped in the cases of the "Oliver Cromwell" and "Calcutta" any effect on the coals?—When I was in the Tyne in June when the "Oliver Cromwell" was loading, I think I remember there was a little drizzling rain, it was not actually dry weather, it was dull and cloudy weather.

1223. It was a dry summer altogether?—Yes, there was no rain to speak of.

1224. (*Mr. Ferguson.*) Do you know whether the coals put into those vessels that were burnt had been long out of the pits or not?—I have no knowledge upon that subject.

1225. Do you know whether in the cases of the shipments from Birkenhead any long interval has elapsed between the time of the coals being wrought and their shipment?—Sometimes they would be fresh wrought, and sometimes they would have remained sometime before being shipped. They have to come some distance by railway. I have known blockages on the line that have prevented our getting coal for some days, the colliery manager has said that it has left the pit but it has been detained in trucks on the line, and there it has been for days and days sometimes.

1226. Were all the ships that you have loaded from Birkenhead ventilated?—Yes, they were always ventilated in the same way.

1227. (*Dr. Percy.*) I think you spoke just now in favor of the system of loading by barrows on this ground, that there was not likely by that system to be the same accumulation in any one spot of small coal or slack?—Yes.

1228. Have you any reason to believe that spontaneous combustion is more likely to occur in an accumulation of fine coal than elsewhere?—The only reason I have for entertaining that opinion is that when coal is loaded by the tips I have always noticed a larger accumulation of small coal in the wake of the main hatch than at any other place, and speaking of the experience I have had in the cases of the "Oliver Cromwell" and the "Calcutta," in both those ships the seat of the fire was in that locality.

1229. Where the fine slack had accumulated?—Where the fine slack had accumulated, and I also asked Mr. Bates before my ships were burned what his information was as to where the fire took place, and he told me exactly in the same locality. An experienced ship master with whom I was talking yesterday, who had been in ships that had been on fire, and had attended three surveys of ships that either came into Bombay on fire or had taken fire while lying there with coal, said that the fire in each case occurred about five feet from the skin of the ships in the region of the main hatchway.

1230. When there was an accumulation of fine slack?—Yes, that is what he attributed it to.

1231. You said that in the case of the Oliver Cromwell the men noticed an unpleasant smoky smell, which is said to be usual in coal-laden ships?—I did not say it is usual, but the apprentice assumed it to be usual in coal-laden ships. He treated it as quite a casual matter.

1232. (*Sir G. Elliot.*) The main hatchway would be where the ventilating shaft would be placed?—Yes, the ventilating shaft would come there.

1233. It was not merely that there was an accumulation of slack there, but that would be where the main shaft for the ventilator would be placed?—Yes, but the mass of small coal would be so dense that the ventilator would not act in the same way there as in the fore and after hatchways, where there would also be upright shafts.

1234. (*Mr. Abel.*) I gather from your evidence with regard to what you believe to be useful ventilation, that what you require is ventilation outside the mass of coal, so as to facilitate the escape of gas from the coals. Is that your opinion?—I cannot say that that is my opinion at all, because my opinion, based entirely upon my experience, is that the ventilation I have hitherto adopted with such success at Birkenhead is the proper ventilation for certain descriptions of coal; what the chemical ingredients may be in other coal which may require a different treatment I cannot say, as I have only had the experience of those two ships; but taking Birkenhead or Cardiff coal, I should adopt the same mode of ventilation that I have hitherto adopted successfully.

1235. Would the object of adopting that mode of ventilation be to guard against fire, or to guard against explosion?—It would be rather to satisfy my underwriters than to guard against anything; for I tell you candidly, that having been free from casualties, I simply adopted that which the underwriters, surveyors, and such like people recommended without looking at it critically or carefully at all. The first thing an underwriter says to you when you are insuring a cargo of coals is "Will your friends see, or will you see, to the ventilation?" They make a special point of seeing to the ventilation.

1236. (*Mr. Young.*) Have you any instructions to try the heat of the coals in the course of the voyage by the thermometer?—I never gave any pointed instructions till recently upon the subject, but I have always

Mr. W. R. Price.

22 June 1875.

told the captains to keep their hatches off to prevent the possibility of an explosion. I have seen a casualty from Cardiff coal in particular arising from keeping the hatches on, but I never told our captains to use the thermometer till recently, though the ships have always been provided with thermometers for the purpose.

1237. Providing a thermometer would be a way of telling telling the captain that he ought to use it?—I should think so.

1238. Do you instruct them to record in the log the heat of the coal?—I do so now.

1239. You did not do so formerly?—No.

1240. If they have a wooden ventilator as you describe, how do they get the thermometer down into the mass of coal?—The sides of the ventilators are two-thirds open, like a venetian blind.

1241. Louvred?—Yes; and any gas or heat that is in the coal will naturally find its way through. By taking the state of the thermometer on deck, and then putting it down and keeping it down for a certain time, and then taking the temperature below, you get at the difference.

1242. I understand you to say that you have been a shipowner for 17 years?—Yes.

1243. Mainly in the East India trade?—Yes.

1244. Practically, your ships have always carried coals?—Yes.

1245. Have those burnings interfered with your trade recently?—Very seriously.

1246. How?—In the question of insurance. The rates of insurance on coal for long voyages are almost prohibitory, to some places entirely prohibitory; for instance, round to the west coast of South America, and to Japan, and those places, and even for shorter voyages from the Tyne, I have been debarred from replacing those two ships with similar vessels or (new colonial ships) simply on account of the amount of insurance. If you are tied to coal cargoes, the cost of insurance now as compared to what it used to be becomes a serious item.

1247. (*Chairman.*) Will you give us what used to be the rate, and what it is now?—For many years the rate I paid to take coals from Birkenhead to Bombay was 60*s.* to 3*l.* 3*s.* per cent.

1248. (*Mr. Young.*) On the hull of the ship?—On the hull of the ship.

1249. (*Chairman.*) And on the cargo, what was it?—About the same; I am speaking of colonial ships. On iron ships it would be lighter; it then rose to 80*s.* or four per cent., and subsequently to 90*s.* or four and a half per cent.

1250. Is that what it is now?—No, it is now 6*l.* 6*s.*, that is the minimum; I had to pay in the early part of the present year as much as 8*l.* 8*s.* per cent. to complete my insurance.

1251. Was that to Bombay?—In one case to Bombay, and in the other to the Madras coast.

1252. (*Mr. Young.*) Do you think that this state of affairs is causing the good class of ships to fall into disuse, and bringing in a lower class of ships?—It is certainly deterring a great number of people from putting them into their high class ships.

1253. The result would be that inferior vessels would be bought for the purpose of carrying coals on those long voyages, the owner probably not insuring them at all?—I have been seriously contemplating doing that within the last 10 days. I have been talking the matter over with my friends, whether it would not be better worth our while to have good sound older ships which are of comparatively little value for the carriage of coal, and take our own risk rather than pay those prohibitory rates, whether it would not be better to take a vessel of 7,000*l.*, or 8,000*l.*, or 9,000*l.* value, and divide it into fourths among my friends, and taking $\frac{1}{4}$ instead of $\frac{1}{2}$, and running my own risk.

1254. That arises practically from the opening of the Suez Canal, and from the fact that ships do not get any outward cargo except coals?—Except coals and salt.

1255. (*Mr. Duncan.*) You find not only that the premium has increased so enormously, but that many underwriters will not take coal ships at any price?—The area of insurance on ships loaded with coal has been limited to an extent that I have never seen in my 25 years' experience, some underwriters decline them entirely; they will not look at them.

1256. (*Mr. Icely.*) You have informed the Commission that in the case of the "Oliver Cromwell" the coal was very small?—It was.

1257. That was your ship?—Yes.

1258. It was not your cargo?—No.

1259. Therefore it was not to your interest to see that the coal was shipped in good condition?—No; I took the coal as it came.

1260. Was that coal inspected?—Yes, I think so; I may say that I did not see the whole of the cargo; it was only what I saw when the ship was half loaded; I saw a dense mass of coal in the region of the main hatchway. I imagine the Peninsular and Oriental Company had their inspector there.

1261. This was for the Peninsular and Oriental Company?—Yes.

1262. In the case of the "Corah" the cargo was also for the Peninsular and Oriental Company?—Yes.

1263. She arrived safely?—Yes.

1264. In the case of the "Oliver Cromwell" the cargo ignited?—Yes.

1265. (*Mr. Fenwick.*) Do you know what quantity of coal the "Corah" had in her?—I should think from her size she must have had about 2,000 tons.

1266. The vessel was not ventilated?—She was not ventilated.

1267. You say that from your adoption of the mode of ventilation which you have adopted in the case of vessels sailing from Birkenhead, you have been kept free from accidents in ships going from Birkenhead?—I am not prepared to assert that that has been the cause of my having no burnings; but I have ventilated the ships, and I have had no burnings and no heated cargoes.

1268. That mode of ventilation has been successful in Birkenhead, but it has not been so in the Tyne. From your experience, supposing you were loading coal in the Tyne, would you ventilate your ships in the same manner as you do at Birkenhead?—I would move my ships to any part of the coast sooner than send them to the Tyne. If I had a ship at Dundee, I would send her round in ballast to Liverpool rather than go to the Tyne, because it is prejudicial to one's business and status to be losing one's ship, though the cause is ascertained, and it is proved, that you are not to blame. I have had sufficient casualties and I do not want any more.

1269. Still the fact remains that the other vessel, to which you referred, that was not ventilated, arrived at port without any accident?—Yes; but a burnt child dreads the fire. I do not want to try any more experiments with Tyne coal.

1270. (*Mr. Cory.*) I understood you to say that you were now contemplating arrangements for taking your own insurance risk?—Yes; it is passing through my mind.

1271. Are you under the impression that there is rather an unjustifiable panic amongst the underwriters and that they are charging too much?—I would put it in this way; they are not discriminating, they are panic struck as regards every port, but particularly so as regards the Tyne. They are not putting a differential rate on the different ports as they ought to do, taking into consideration the number of casualties in vessels sailing from one port as compared with vessels sailing from other ports.

1272. Have not the premiums gone on increasing on other risks besides those on coal laden ships?—Not to anything like the same extent.

1273. But to some extent?—On some voyages they have; on some risks they are very much lower.

1274. Lower than they were five or six years ago?—Yes, unquestionably; you may take it thus; that in a business like coals or rough cargoes, generally the rates are higher; but on those things which the

Mr. W. R. Price.

22 June 187

underwriters have lost enormously, such as steamers through the Suez Canal and on goods coming from Calcutta, they are decidedly lower than they were some years ago. Directly we get a rough risk, that is to say, a rough cargo, coals or salt in a wooden ship, the underwriters do not care to name a rate, but particularly when we get coals.

1275. (*Mr. Vivian.*) Do you attribute the immunity from accident in the case of coal shipped from Birkenhead to the character of the coal or to the ventilation which you adopted?—I am inclined to think that it is a great deal more from the character of the coal than anything else.

1276. Have you known cargoes of coal from Birkenhead which were not ventilated take fire?—I do not know whether they have been ventilated or not, but I had recently through my hands a list of 834 coal-laden ships that sailed in 1872, 1873, and 1874 from Birkenhead to all parts of the world, a large number of them to the East. I put that list in the hands of the secretary of Lloyd's and asked him to have the books and records of Lloyd's searched and to give me the results of the voyages of those vessels. Some of the 1874 voyages were not then ended, but the result as far as I remember was this, that out of the 834 ships there were only three known to have been burnt, or supposed to have been burnt, and five missing.

1277. Or they may have foundered?—Yes, it was three or four months ago that that came before me. Therefore I am bound to consider with such a large number of ships, and such a small per-centage of burnings, there must be something in the coal itself.

1278. Have you had any experience of shipment at Cardiff?—I have had some experience, but nothing like the experience I have had at Birkenhead.

1279. Would you ventilate Cardiff coal, or would you not ventilate it?—I always have ventilated Cardiff coal when I have shipped it.

1280. Have you had any cases of spontaneous combustion from coal shipped at Cardiff?—No, not as a shipowner.

1281. Have you shipped any unventilated coals from Cardiff?—Never.

1282. Do you know of any unventilated coals having been shipped from Cardiff?—I do not.

1283. You said that the fires chiefly occur in the main hatchway, and you attribute it to the smallness of the coal in the hatchway?—Yes, to the density of the mass.

1284. It is customary, is it not, to load coal at the other hatchways as well as the main hatchway?—Yes, they trim the cargo in that way; when they cannot trim it by hand easily, they move the ship to load the coal at the ends.

1285. Ships constantly take coal on board at all the hatchways, do they not?—Yes.

1286. Why do you think that the coal becomes more liable to spontaneous combustion at the main hatchway than at other hatchways?—From the facts that have come before me I have found that it is in that direction the fires occur; the great bulk of the cargo goes in at the main hatchway; it is only a small proportion that goes in at the other hatchways.

1287. Have you ever shipped coal or taken coal on board under the box drops?—I cannot call to mind that I have.

1288. I presume your reason for preferring barrows to tips is chiefly from the breakage of the coal in the hatchway itself?—No, I have no interest in the breakage except the cargo is my own, and even then very little, because it is generally sold on the endorsement on the bill of lading. One of my preferences for the barrow system is founded on this, if you are loading by tips sometimes if the captain is away they will carelessly put in too much at one end, and the ship will strain herself, whereas when you are loading by barrows you can wheel them where required so as to trim the ship exactly as you want.

1289. That applies to the trimming of the ship. I am speaking of the liability to spontaneous combustion and the production of small coal; supposing small coal were not introduced into the hatchway by the adoption of another system of shipment, namely, by the box system, would that remove your objection to shipment by tips?—Next to the system of loading by barrows I should prefer the coal being loaded in boxes in the way you speak of.

1290. I presume when a column is once formed in the hatchway the liability to produce small coal is no longer so great?—I have always seen it come up in a pinnacle of small coal to the very top, and as long as there is room for it to run clear of the hatchways the big lumps of coal run down and the small coal generally culminates.

1291. After that there is not the same liability to breakage?—There is not the same liability to breakage.

1292. So if you formed your column in the hatchway by boxes and then used the tips the difficulty you have mentioned would be got over?—It would be got over to some extent certainly.

1293. (*Chairman.*) Your evidence has only gone to the shipment of steam coal, have you had any experience in the shipment of smithy coal or any other coal?—Nothing to speak of. The firm with which I was connected used to ship smithy coal largely to Bombay as merchants, and we never had any accident with it.

1294. Your evidence hitherto has been only as a shipowner, I believe you have been an insurance broker also?—Yes.

1295. Have you had any experience as an insurance broker with regard to this question?—I have had 25 years' experience as an insurance broker in London.

1296. Have you had any experience on this particular question, have you had any experience of cases of combustion in ships which you have insured?—Yes.

1297. Could you give us an outline of that experience?—I have not gone back many years because one's memory is treacherous upon these things, but in October 1867 I insured a ship called the "Sir George Seymour" from Birkenhead to Bombay, in which ship spontaneous combustion took place; that is the only case of burning in a vessel sailing from Birkenhead that has ever passed through my hands in my 25 years' experience, insuring coal to all parts of the world, or that I have known. In October and November 1871 I insured for two different owners a portion of the value of the ships the "Sea Pink" (a colonial ship,) and the "Baringa" (an iron high-class ship). Both loaded from the Tyne and both sailed for Bombay and neither of them was ever heard of; being well formed ships and well owned ships, the conclusion in my mind always has been that they were burnt.

1298. Do you know what the name of the coal was?—No, I do not. I am under the impression that I have seen in a parliamentary paper a list in which those two ships are included, where the name of the coal is given. So, assuming that those two missing ships were burnt, my experience embraces five ships, one of which was from Birkenhead, and four from the Tyne.

1299. You have been concerned with considerably more ships from Birkenhead than from the Tyne?—As an owner.

1300. And also as an insurance broker?—Of late years I have been more concerned with ships from Birkenhead, but previously from the Tyne also.

1301. A large number of them being coal ships?—Yes, to all parts of the world.

1302. You spoke of the rate of insurance having very much risen on coal. Does that high rate maintain itself at the present moment; has there been no fall lately in the rate since coal fell in value?—I have not perceived it; on the contrary, I have found increasing difficulties. For instance, if you have a ship going out of Birkenhead valued at 5,000*l.* you can find an area of underwriters for that vessel at say, taking Bombay, 6*l.* 6*s.* per cent., but if you have a ship of 15,000*l.* value you either have to send to Land's End, or John o'Groats, or to Paris for insurances before you can get

Mr. W. R. Price.

22 June 1875.

such an amount as that insured, except you pay an enormous premium.

1303. Are you speaking of coal ships ?—Yes.

1304. You said you had an idea of ceasing to insure your coal ships and of spreading the risk among a limited number of friends. Would not you in such a case have very much higher wages to pay ?—No the sailors never question whether you are insured or not. I should think if anything I ought to pay lower wages; they would infer that my ship was so well found that I was prepared to take the risk of her.

1305. It would not be an objection to the ship ?—No, on the contrary, I think the minds of people would be operated on by the fact that the owner has so much confidence in his ship that he will not insure her.

1306. (*Mr Fenwick.*) You have mentioned five cases where the ships have been lost or not heard of, can you inform us how many ships you have insured in your experience ?—I cannot; it must have been a great many.

1307. Having the great experience you have, and having insured so large a number of ships, it would be very desirable if you could tell us approximately the enormous amount you have insured as compared with the five vessels that have been lost ?—Having paid as much as 60,000*l.* in some years for premiums, and 40,000*l.* perhaps on the average for the last 20 years, I must have had to do with a great many coal ships in my time. Some of the ships would be only loaded partly with coals.

1308. (*Chairman.*) You have had a hand in insuring hundreds of coal ships a year ?—In some years, certainly.

The witness withdrew.

Mr. R. J. Hancock.

MR. ROBERT JOHN HANCOCK examined.

1309. (*Chairman.*) You are a Bristol merchant, I believe ?—I am shipping manager to Messrs. Charles Hill and Sons of Bristol and Cardiff.

1310. You have had great experience in connexion with the shipping of coal ?—I have had many years experience in it.

1311. You have been concerned in shipping many thousand tons of coal, I believe ?—I have shipped about 75,000 tons of coal during the last ten years.

1312. What coal has that been chiefly ?—All the various kinds of steam coal shipped from Cardiff and Newport. I could not give you the names of the pits. I have also shipped several cargoes of smelting coals.

1313. Have you had any cases of spontaneous combustion or explosion ?—We have never had a case of explosion. We have had one case, not of actual spontaneous combustion, but of coals becoming very much heated. That occurred in the case of a ship called "Her Royal Highness." The captain, fearing to go on to Cape Horn with them, sold the coals at Monte Video, finding that the expense of landing them and re-shipping them would be more than they were worth.

1314. That is the only case within your experience? —Yes.

1315. That being so, what precautions do you take with respect to ventilation, or with respect to the shipping of your coals ?—We always carry our coals on a platform from 16 to 20 inches from the bottom of the ship, so that there is always a cool place, and then the bottom of the coals does not get wet. I think wet is a great cause of spontaneous combustion.

1316. Have you any special ventilation ? Have you any ventilators up to the hatchways ?—We put iron ventilators as far forward as we can get them, and as far aft as we can get them, down through the poop. We put a ventilator in each hatchway.

1317. Is your experience that that system of ventilation is sound ?—I can only judge from our ship's having gone free from accident.

1318. Have you compared your immunity from accident with the casualties of others ?—Only in a general way. I know that a great many of the ships that have been burnt have carried their coals upon the bare skin of the ship, and that they were very often wet at starting.

1319. I understand you to say that you would recommend that all coals should be carried on a platform ?—Yes.

1320. Have you any recommendation to make with respect to the manner of taking coal on board ?—I think if it were possible to take only large coal on board at first, so as to have in each hatchway a good pile of large coal, and no small coal, it would to a great extent tend to prevent spontaneous combustion.

1321. How has the coal generally been shipped in the ships of which you have had experience ?—By tips.

1322. Always by tips ?—Yes.

1323. You have had no experience of the system of lowering by barrows ?—None whatever.

1324. And yet you say that your coal has been remarkably free from accident arising from spontaneous combustion ?—Yes, I think I can fully account for the near approach to accident in the ship I have mentioned. She was a new vessel, and very flat in her bottom, and in putting the platform in, which we do as much to ease the ship as for ventilation purposes, we kept it as high as we thought she would bear it, and after she had been at sea a few days they found that she was top heavy. They took her back to Cardiff, and discharged part of the coals, and while the coals were lying on shore it rained very heavily, and the coals got wet. They took 600 or 700 tons out of the middle of her, and took up the platform; and when they put the coals in again they let them run down on to the bottom. I think that fully accounted for their heating, and I further think that if she had gone out with the original platform no accident would have happened.

1325. Do you think that that accident arose from the coal getting wet, or because there was no platform at the bottom of the ship, and consequently no ventilation ?—Both combined I think tended to produce the heating.

1326. Was there any special report sent to you of the chemical cause of the combustion; was any special survey held ?—No. We always instruct the master to ascertain the heat of the hold with the thermometer; in doing this the captain stated that he found the hold getting gradually heated, and at last he took the main hatches off and forced iron bars through the coals as far as he could get them, and on withdrawing the bars they were so heated that a match would ignite against them; he then felt satisfied that the coals were very near ignition, and he ran back to Monte Video.

1327. Was there any suggestion that there was much iron pyrites in the coal ?—No; but I have always understood that that is the cause of spontaneous combustion; this cargo that I am speaking of was smelting coal.

1328. Do you know what the coal was ? Do you know from what pit it came ?—No; it was shipped at Cardiff for Messrs. Henry Bath and Son, of Swansea; it was a cargo of 1,800 tons.

1329. So that in all your experience of coal shipped from the tips, you have been entirely free from casualty, except in a single case where the platform which you uniformly insist upon had been taken up, and where the coal remained on the bottom of the ship ?—Yes.

1330. And you attribute that one casualty to the neglect of that precaution ?—I do, entirely.

1331. (*Mr. Vivian.*) Have you ever shipped coal by box drops, where the box is lowered through the hatchway ?—Yes; at the commencement sometimes they are used in putting the first part of the cargo in.

Mr. *R. J. Hancock.*

22 June 1875.

1332. Do you consider that system a good one ?—I think it must tend to lessen the force of the fall; the impact would be less in the bottom of the ship.

1333. You said that you preferred the main hatchway being filled up with large coal ?—I think it would tend very much to reduce the tendency to spontaneous combustion if care were taken in stowing the first portion of the cargo by putting in large coal.

1334. In shipping by the box you would attain that end ?—To a certain extent ; the box is not lowered down the entire depth ; you have a fall, perhaps, of 14 feet.

1335. The box is lowered frequently through the hatchway, is it not ?—I have never seen it lowered down to the bottom.

1336. Do you know the system adopted in the Alexandra Docks, at Newport ?—I was there the other day; we have a ship loading there. I saw that they had a new system, but I had not an opportunity of seeing it at work.

1337. (*Mr. Fenwick.*) You say that in all your vessels you have this platform at the bottom ?—Yes.

1338. Is that plan generally adopted among shipowners ?—Most vessels in the Callao trade have platforms for carrying guano cargoes.

1339. Is this platform erected solely for the purpose of ventilation, or for the purpose of raising the cargo up off the bottom ?—It is erected for the purpose of raising the cargo off the bottom, and also for the purpose of ventilation. I have here a sketch of it (*handing it in*).

1340. I understand that the platform is put in chiefly for your return cargo ?—Not necessarily; in going to India we always put those platforms under the coals, and we then take them up and make dunnage of them for stowing the homeward cargo.

1341. Is it your impressson that it is very desirable that the coal should be kept free from wet ?—I think it is very desirable. I know there is great carelessness in loading coal; people treat it the same as ballast almost, and they very often allow the rain to go down the hatchways.

1342. You appear to think it very important that there should be large coals in the hatchway ; why do you advocate the stowing of large coals in the hatchway ?—Because I think the danger of spontaneous combustion arises from the small coal. I do not think if large nobs were stowed in by hand there would be any such thing as spontaneous combustion. I think the fire generally takes place in the hatchways underneath the drop.

1343. (*Mr. Icely.*) What is the quantity of coal that you think you superintend the shipment of yearly ?—Some years it is considerably more than others ; last year we took a great deal of iron out. I have shipped 75,000 tons in 10 years ; some years it has been 7,500 tons ; in some years double that; and in some years it has not been so much.

1344. At what period was it that you had this one casualty that you speak of ?—It was in 1865.

1345. During the whole of the 10 years you have had but that one casualty ?—That is the only one.

1346. Have you during the whole of those 10 years had your ships ventilated ?—We have had them ventilated in the manner I have spoken of, never otherwise.

1347. Have you been in the habit of taking the temperature of the cargoes ?—The captains have been instructed in a general way to watch by the thermometer if there is any heating in the hold, and to keep the hatches off in fine weather.

1348. Are they instructed to try the temperature at any specified period ?—They have not been so instructed.

1349. They have been left to exercise their own judgment ?—Yes ; I think in future I shall direct the captains to record the temperature in the ventilators of each hatchway in the log-book at noon daily.

1350. (*Mr. Young.*) You have stated that you have shipped 75,000 tons of coal in 10 years, that would be 50 or 60 cargoes, I suppose ?—68 cargoes ; some of the cargoes have reached 2,200 tons ; we had one cargo last year, which we sent on our own account to India, which was on board for six months before it was sold.

1351. (*Dr. Percy.*) You spoke of the importance of protecting coal from wet ; what reason have you for believing that moisture renders the coal more likely to ignite spontaneously ?—Our only accident is one reason, and I gather that that is the opinion of people who are constantly shipping coals and also of coal owners.

1352. Is it an impression simply, or can you give any well-established facts in justification of that opinion ?—The only fact I can speak to is our own approach to an accident.

1353. You say the fire generally occurs underneath the drop—is that the place where the fine coal is likely to accumulate ?—Yes.

1354. (*Mr. Ferguson.*) With regard to your vessel that took fire, was it ascertained that water had got on to the coals in the voyage out ?—She made some water in the top sides, but the coals were very wet when they were reshipped.

1355. (*Mr. Duncan.*) It would be the water they got on shore, rather than from any water that they got in the ship that you would attribute the heating to ?—I think so.

1356. Therefore the platform in that case would not have very much to do with it ?—Only if there were no platform there would not be the advantage of the cool air under the platform, and the coals could not drain if they had any moisture in them.

1357. Did you have a shaft up from the platform ?—Yes ; up each hatchway.

1358. You had no ventilation among the coals by the side of the keelson or otherwise, above the platform ?—No.

1359. (*Chairman.*) You said that of late you have paid more attention to this question of spontaneous combustion of coal than formerly, and that you give more specific instructions to your captains ?—Some years ago accidents rarely occurred, but since they have been more numerous we have instructed the captains to see that the ventilators are kept clear during the loading.

1360. Though you have not lost a ship during 10 years from spontaneous combustion, the question has assumed greater proportions lately ?—There have been a great number of accidents, but whether they are greater in proportion to the amount of coals carried or not I do not know.

1361. At any rate, your attention has been drawn to it more prominently lately ?—Yes.

1362. The Chamber of Commerce of Cardiff has taken great pains with regard to this question ?—Yes.

1363. Were you one of those who took part in the inquiry they made ?—Only in connexion with Mr. Hill. I am frequently in Cardiff, and he and I have talked this matter over together; he is president of the Chamber of Commerce of Cardiff.

1364. As president of the Chamber of Commerce of Cardiff, with your assistance, he has gone a good deal into this question ?—Yes ; he has furnished some statistics of the number of vessels lost.

1365. Am I right in saying that you are acquainted with the statistics which Mr. Hill has prepared ?—I have seen them. I saw them before they were printed.

1366. Did Mr. Hill consult you in the preparation of those statistics ?—He was about them when I went to Cardiff, and they were put before me. I went over several figures with him.

1367. Is the result of the inquiries made by your firm, which Mr. Hill in his capacity of president of the Chamber of Commerce has put forward, that the per-centage of loss by spontaneous combustion, whether measured by ship or measured by the quantity of coal, is not over one half per cent. ?—That is shown in this statement.

1368. That is over the whole kingdom ?—Yes, that is the result as shown by the statistics published up to October last.

Mr. R. J. Hancock.

22 June 1875.

1369. On the subject of ventilation, is it the result of those inquiries that ventilation is very dangerous to one class of coal, and very necessary for another?—I do not think ventilation could be dangerous in any coal, but after a fire once occurred no doubt the ventilators would tend to feed it. I do not think ventilators would tend to cause the fire.

1370. Do you know whether there is any increase in the premium which is now charged on these risks?—I know that we pay very little more.

1371. Can you recollect what you used to pay?—I do not think that we are paying any more than we did seven or eight years ago.

1372. Is that because you have been so remarkably free from accident?—I take it that it is because we have been free from accident, and go to the same underwriters, and because we take a large amount of the risk ourselves.

1373. Your experience is that the rates of premiums on your coal-laden ships are pretty much what they used to be?—We do not pay more than one per cent. over, we should not pay more than one per cent. extra in taking a coal cargo as compared with any other cargo. I am speaking of voyages round the Capes for instance. We take a third of the risk always ourselves.

1374. Where are your risks taken?—In London.

1375. At Lloyd's or by companies?—Partly at Lloyd's and partly by companies.

1376. (*Mr. Fenwick.*) Is it the fact that you do not pay more than one per cent. more than you paid seven or eight years ago?—I may say positively that we do not.

1377. (*Mr. Duncan.*) Are any of your ships loaded with a general cargo from London?—Yes.

1378. What would be the premium on a ship loaded at Cardiff with a general cargo?—35*s.*

1379. What is the premium when you load the same ship with coals?—Coals to India would be higher at any time. When I said the premiums were not higher I should have said as compared with any other heavy cargo; the difference between the premium on a general cargo and the premium on a cargo of coals that we used to pay, did not arise so much from the danger of spontaneous combustion as from the weight. The underwriters prefer a general cargo to a weighty cargo. We do not pay more than one per cent. for coals over what we used to pay.

1380. That is to say, you are speaking of your Bristol Channel cargoes, machinery, and so on?—Yes.

In 1866–7 we paid on good colonial built ships with coals from Cardiff to the west coast of America - -	90*s.* to 105*s.*
And on similar vessels with salt to Calcutta - - - -	80*s.*
And with coal to Calcutta - -	84*s.*
In 1873–4–5 we paid on same class of ships with iron and machinery cargoes to West Coast of America - -	80*s.*
And with coals from Cardiff to ditto -	90*s.* to 105*s.*
One new colonial ship with 2,000 tons coals Cardiff to Valparaiso, was insured at - - - -	60*s.*
In 1874, on a colonial ship 9 years old, with coals, Cardiff to Cape of Good Hope, Galle, and a port of discharge in India we paid - - -	110*s.*

Most of these rates includes shifting to a loading port in England, or on to the Guano Islands after discharge of the outward cargoes.

The witness withdrew.

Mr. T. Beynon.

MR. THOMAS BEYNON examined.

1381. (*Chairman.*) You are a magistrate at Newport?—I am.

1382. What is your business?—I am a shipowner and coal merchant.

1383. I think you have had considerable experience in the shipment of coal?—Yes.

1384. Spread over a good many years?—15 years.

1385. Could you give the Commissioners roughly any idea of the number of cargoes you have been concerned in shipping?—I shipped perhaps 80,000 tons last year.

1386. In the course of your experience you have had several cases of spontaneous combustion at sea?—I have had one case in one of my own vessels, and two cases came under my jurisdiction as a magistrate, the "Minnie Graham" and the "Herbert Graham."

1387. The ship of your own that suffered in this way was the "Usk?"—Yes.

1388. We will take that first; in what year did the casualty happen?—She was a bark of 338 tons register, and she loaded a cargo of smelting coals at Swansea. That was in the year 1861.

1389. Was that cargo taken on board under favourable circumstances?—The weather was wet when the coal was shipped.

1390. How was the coal put on board?—The wagons were tipped into the shoot. The shoot rested on the ship's combings leading to the hold. The wagon was tipped up and it was eased off by the wing. The fall was gentle and the coal fell nearly perpendicularly.

1391. You say the weather was wet?—Yes, and the coal was wet, no doubt.

1392. What ventilation had you in that ship?—There were four pieces of wood running along very near the ship's bottom, and crossed with battens, and from this main shaft, as I may call it, there were similar shafts coming up through each hatchway.

1393. Was this a sort of a platform?—No, it was a kind of square pipe running through the ship, battened over.

1394. About how broad was it?—It was about 14 inches square, and there were shafts of the same description coming up through each hatchway.

1395. It would not protect the coal from wet if there was any wet in the ship's bottom?—No; personally, I have no faith at all in the ventilation of smelting coals.

1396. Do you know from what pit this coal came?—I do not know. It was the usual smelting coal. It was shipped by Messrs. Bath and Sons.

1397. How long had the ship been out?—88 days. They were 200 miles south of Valparaiso when they first discovered it.

1398. Were there any circumstances of special note in the way it was discovered?—The men complained one morning of great heat in the forecastle. The captain went down, and on opening the forehatches, a flame burst up as high as the foretop, and they immediately abandoned the ship. They had to get out a boat before the rigging was destroyed.

1399. They saved themselves?—They were picked up two days afterwards.

1400. This occurred about 14 years ago?—About 14 years ago. There is one circumstance connected with that ship that I would like to mention as showing the difficulty in accounting for spontaneous combustion. On the previous voyage she loaded a similar cargo precisely at Swansea; the captain went out, and having got as far as Cape Horn, he brought the ship right back to Newport, and he said that the Almighty had come on board at Cape Horn and warned him not to go any further. I came up to see the underwriters and they said they did not think they were bound to carry on the insurance, but looking at the circumstances of the case they would do so, but they asked me to discharge the ship so as to see whether the coals were heated. I discharged the coals out of the main hatchway, and the coal was thoroughly cool from top to bottom, and the ship went out and discharged her cargo with perfect safety.

Mr. T. Beynon.

22 June 1875.

1401. It was not commanded by the same captain after ?—No.

1402. That is 14 years ago, and that is the only instance of spontaneous combustion that you have had in your own ships ?—Yes.

1403. Was there any inquiry in that case ?—None whatever.

1404. The other two cases you have mentioned are the "Herbert Graham" and the "Minnie Graham ?" Yes.

1405. And those came before you as a magistrate ?—Yes.

1406. You were one of the members of the court of inquiry ?—Mr. Hewertson, the then mayor, and myself were the magistrates.

1407. We have the minutes of the inquiry before us, but will you give shortly the leading features in each of those cases and state the impression they produced upon your mind ?—Samples of the coals were produced in court similar to that with which the ships were loaded ; they seemed to have come from several mines ; they appeared to be an inferior sort of coals altogether.

1408. Those casualties occurred at the end of 1873 ?—Yes.

1409. Will you first take the case of the "Herbert Graham ;" that inquiry I believe you held in the early part of 1874 ?—Yes. She left Newport, I see, on the 1st July 1873.

1410. How long was she out ?—From recollection, I think about 100 days.

1411. What coal had she on board ?—She had coal from different mines ; it seemed to have contained a great deal of iron pyrites.

1412. Was it all steam coal ?—It was all smelting coal ; what we call house coal at Newport.

1413. Where was she bound to ?—To Valparaiso.

1414. Do you remember how she was ventilated ?—No, I cannot say.

1415. What impression did the inquiry produce upon your mind as to the cause of the casualty ?—The impression that the inquiry produced upon my mind was that the coal was small, containing great quantities of iron pyrites, and I think it was shipped when the weather was wet.

1416. Do you remember how it was shipped ?—By the tip, something similar to the mode I described in the case of the "Usk."

1417. Was it stated in evidence that the coal must have been wet ?—I think it was. I think it was so stated in the evidence of the shipper.

1418. Then is it your impression that the system of shipping by tip is objectionable ?—No, I do not think it is. I do not think you could find a better mode of shipping coals than that.

1419. Then what precaution do you think was omitted in the case of the "Herbert Graham" ?—I do not think there was any precaution omitted at all, I believe it is only a question of time when such coals will take fire. If a cargo of smelting coal were shipped under the same conditions you could calculate almost to a day when they would take fire.

1420. What do you mean by the same conditions ?—If similar coal was shipped damp.

1421. Your opinion is that smelting coal if shipped damp will to a certainty fire after a certain time ?—I think it is almost inevitable unless it is shipped in a different manner than shipping it in bulk.

1422. And your opinion is that no method of ventilation will guard against casualty in the carriage of such a cargo shipped under those conditions ?—I think not, because the coal is so small and it gets so hard that ventilation would be useless ; it would not penetrate through the cargo.

1423. All that you recommend is that greater precautions should be taken to ship the coal dry ?—Further than that, I would recommend that the coal should be shipped in casks or barrels. I think that would be a sure preventative against spontaneous combustion.

1424. You would advise that it should be made a law or regulation to ship all smelting coals going to a great distance in cask or barrels ?—Yes, it does not follow that they should be very sound barrels ; the object would be to isolate the coals by separating them into small quantities. I believe that shipping the coals in barrels would be a sure preventative. In the case of the "Herbert Graham" the chemist that came down from the Board of Trade (Mr. Vassard) stated that carbonic acid or sulphurous acid, I forget which, if generated in proper quantities and introduced into the hold of a ship on fire from spontaneous combustion would put out the fire, and he put before us a very elaborate plan of introducing pipes into a ship's hold, running fore and aft in the sides and in the centre of the ship and they were to be perforated. We knew when the inquiry was finished that the "Minnie Graham" had been lost, and he stated that if the inquiry on the loss of that vessel was held in Newport he would bring his apparatus down and show us the manner in which he proposed to put the fire out.

1425. Was the "Minnie Graham" lost about the same time ?—She was lost a little after. They were both loaded in Newport with the same coal, and they were both lost under similar circumstances.

1426. I understand you to say that in both cases the coal was shipped damp ?—I think it is in evidence that the coal was shipped damp.

1427. Did this gentleman bring his apparatus down ?—He did, and during the inquiry he got a large fire made up in the court house, and he got a piece of wood to fit the front of the fire to prevent the air getting into it, he got his gas made and introduced it into the fire, but he nearly set fire to the court house ; he did not put the fire out.

1428. Do you mean it was his recommendation that all ships carrying smelting coal or house coal to distant places should be obliged to be fitted up with this special machinery ?—He recommended this system and I have no doubt it might answer if the air was totally excluded. I do not know whether it would or not ; but I mentioned to him my method of stowing the cargo in casks and he agreed with me.

1429. The members of the court of inquiry did not endorse his recommendation ?—Not under the circumstances, we had to put the fire out.

1430. I take it that your judgment is, so far as your experience enables you to give an opinion, that all that is required to be done in the case of smelting and house coal going on a very long voyage is to ship it in casks ?—I think all coal liable to spontaneous combustion, that is to say, containing iron pyrites and shipped in damp weather ought to be shipped in casks.

1431. Would you extend that to steam coal ?—No, I have never seen a well authenticated account of pure South Wales steam coal taking fire by spontaneous combustion.

1432. Do you know of any cases of spontaneous combustion in north country coal ?—No, but I know that during the high prices in South Wales they shipped coals as steam coals that were not steam coals, and some of the ships carrying those coals took fire. I do not think that a cargo of South Wales first-class steam coals would take care by spontaneous combustion.

1433. Would you apply a different mode of ventilation to steam coal from that which you would apply to smelting coal ?—I have always found in loading my ships with steam coals that if I keep the hatches off for a certain time after they are loaded it is a sufficient safeguard, and if a ventilator is introduced through the poop into the hold and another through the other hatchway it will carry off all the gases.

1434. Without any longitudinal method of ventilation ?—Yes.

1435. To keep the surface of the coal well ventilated ?—To keep the surface of the coal well ventilated, and I should allow no one to go into the hold without a safety lamp.

1436. That is more to guard against explosion ?—Yes.

Mr. T. Beynon.

22 June 1875.

1437. From your experience those are the recommendations which you would give to the Commissioners?—Yes, I believe what I propose would be a sure preventative, and a very trifling matter of expense.

1438. Have you any other suggestion to make of the same character?—I feel so convinced in my own mind that the precautions I have suggested would be a preventative that I do not think any other precaution would be necessary.

1439. Would it be your advice that those precautions should be matters of law or would you leave it to the interest of the merchant to adopt them?—I am very much adverse to compulsory legislation. I think it might be left to the intelligence of the underwriters and shipowners if the underwriters say we will not insure a ship under a certain premium unless the coal is shipped in casks that would meet the case I should think, but if it would not I would rather see a compulsion for the sake of insuring safety.

1440. You would trust in the first instance to the publicity which perhaps the report of this Commission might give to some desirable rule than make it a question of Parliamentary enactment?—I think so at first.

1441. Have you any information to give us with regard to the present premiums that are charged on the shipment of coals from your part of South Wales?—It would depend on the ships. I should think that the premiums paid on ships going out with coals from South Wales to the west coast and coming back with nitrate would be 100*s.* per cent. if the owners are known to the underwriters.

1442. Has there been any change during the last few years?—The tendency is for premiums to go up especially on coal-laden ships; upon a ship which has just gone out from the north I had to pay 10 per cent. on her passage outwards—that was from Sunderland to Calderan.

1443. Was she a good ship?—She was a good ship because I ensured her at 80*s.* on the previous trip on the round.

1444. Was that with a coal cargo?—Yes, it was smelting coal from Newcastle in each case.

1445. Have you had any casualty from fire in ships of your own sailing from the north?—No.

1446. Is it your experience so far as South Wales is concerned that there has not been any serious rise in the premiums charged on good coal ships?—I have not insured a ship since the late losses, but I think the underwriters charge more on ships carrying coals to the west coast of South America.

1447. Both from South Wales and the north?—Yes.

1448. You have not had to insure a ship yourself lately?—Only one from the north.

1449. You have not had to insure a ship yourself from South Wales?—Not since the inquiries into the loss of those ships—not since the early part of 1874.

1450. (*Mr. Vivian.*) You say you consider that smelting coal will always take fire; do you mean that all sorts of smelting coal are liable to spontaneous combustion?—The common smelting coal that contains iron pyrites I think is very liable to take fire if it gets damp, but about the same time that the "Minnie Graham" and the "Herbert Graham" were loaded at Newport, I loaded a ship with steam coal mixed with large coal. I put two trucks of small coal to one of large coal. She went out to Coquimbo; it was Monmouthshire coal, which is a semi-bituminous coal; and I had a letter from the company to whom I sold the cargo in which they said it was the finest smelting coal they had ever had, and it turned out perfectly cool. It was in the proportion of two trucks of small coal to one truck of large coal.

1451. What coal was that?—A coal called the Tilleary coal; we shipped it as Beynon's black vein smelting coal.

1452. That is a case of smelting coal not liable to spontaneous combustion?—There was no casualty in that case. It was what they term a pure smelting coal. It was an experiment on our part. We recommended the coal, and it turned out equally good coal as the other. I suppose being a pure steam coal it did not contain so much iron pyrites.

1453. Very large quantities of smelting coals have been shipped from South Wales?—Very large quantities.

1454. Can you tell at all what proportion of those coals has caught fire?—I could not say from memory.

1455. But nothing like the whole?—Nothing like the whole.

1456. It is hardly correct to say that all smelting coals must necessarily catch fire, is it?—I qualified my answer by saying that I believe that all smelting coal that contained a large quantity of iron pyrites and which was shipped during wet weather would inevitably take fire.

1457. Are you aware that some of the smelting coals shipped from South Wales have never taken fire?—Yes; the "Usk" on a former occasion loaded a precisely similar cargo, and after being out 154 days she arrived safely at her destination.

1458. What coal was that?—It was shipped by the same firm.

1459. The Messrs. Bath purchase coal from many different people, do they not?—Yes; I do not know what the coal was. I know they shipped both cargoes.

1460. The origin of the two coals might not have been the same?—No.

1461. Are you aware that there are different kinds of smelting coal shipped at Swansea?—Yes.

1462. And some of those have never been known to take fire?—I know that several ships loaded with smelting coal from Swansea have never taken fire.

1463. You are not able to state what coals shipped at Swansea are liable to take fire, and what are not?—I could not specify them.

1464. What would be the cost of shipping coals in barrels?—As a shipowner, I have not gone into that question, but I would be glad to take a cargo of coals for 2*s.* 6*d.* more per ton, I finding the barrels.

1465. Are you aware what the value of barrels is?—I do not know what they would be in large quantities. I should think empty flour barrels, or old hogsheads or sugar hogsheads, would be the proper things to use for the purpose.

1466. A sugar hogshead is worth, I think, 5*s.* or 6*s.* What quantity of coal would a sugar hogshead carry, probably about 7 cwt. or 7½ cwt?—I am not able to say how much it would carry. It would add materially to the cost if that is the case. I do not think the old barrels would cost as much as 5*s.*; a trade would spring up in them no doubt. If you want hogsheads for a certain purpose, you have to pay more for them than if you took thousands of them every year.

1467. Are there many old barrels to be got at the shipping ports?—I should say there is an immence number at Liverpool.

1468. How would you get them from Liverpool to Newport?—I would bring them down.

1469. That would cost a great deal?—I have not gone into the cost. I am only saying what I am firmly convinced would be a sure preventative against spontaneous combustion. I think it would be much cheaper on the whole than the scheme recommended by the chemist, who propose to introduce iron pipes through the ship's hold, and pass carbonic acid through them. I think it would be a difficult matter to make carbonic acid in a gale of wind at sea. I believe if the coals were stowed in old bags even, it would prevent spontaneous combustion, so long as they were not stuck down close together; so long as there are interstices between the bags it would be a preventative, but storing the coal in bags would not be so good a plan as stowing it in old casks.

1470. Do you think that it would be possible to get the number of old casks requisite, even supposing the expense were not too great?—Yes.

1471. The casks would have to be brought from other ports?—They might make them at the ports where the coal was shipped.

Mr. T. Beynon.

22 June 1875.

1472. A new hogshead would be a very expensive thing?—It depends upon what kind of hogshead you have.

1473. At all events you have not gone into the question of the cost?—No.

1474. You know no doubt the system adopted of shipping coal in the new Alexandra Docks at Newport; I believe under that system the coal has a short distance to fall?—It all depends on the depth of the ship's hold.

1475. Do you know whether provision is made for avoiding the fall from the ship's deck to the keelson?—I have not seen it in operation in the new dock. I have not seen them shipping coal since the docks have been opened. In the old dock we generally adopted the plan of lowering 50 or 100 tons in baskets to break the fall of the others.

1476. The old system of shipping coals was lowering a certain quantity in baskets, in order to break the fall of the others?—Yes, and they adopt that plan now in soft coals—they lower them through the hold.

1477. Can they ship a considerable quantity by baskets in a day?—Yes, but it is more expensive.

1478. What quantity can you ship in a day by baskets?—About 400 or 500 tons.

1479. Is it quite practicable to fill the hatchway up to a certain height by baskets and then to commence with the ordinary coal drop?—Yes, that is done generally with deep ships where there is a heavy fall; they lower a certain quantity down by baskets. I think, with regard to the royal mail steamers, they made it a contract in their charter that the coal should be so lowered.

1480. You cannot state what coal it was that caught fire in the two cases you gave, namely, the "Herbert Graham" and "Minnie Graham"?—In the case of both the "Herbert Graham" and the "Minnie Graham," three or four different sorts of coal went to make up the cargoes; they did not buy all the coal from the same man.

1481. Can you state what the different sorts of coal were?—I think it is stated in the evidence; it says in the case of the "Herbert Graham" that the stiffening was all brush coal, which came principally from the Mamhole Colliery; then there was small coal from Coalbrook Vale, and some from Cwm Serchen, and there was large coal from the Cwm Colliery at Aberbeeg; there were four different sorts of coal.

1482. And in the "Minnie Graham?"—In the "Minnie Graham" there were 60 tons 3 cwts. of Hope large coal, 20 tons 6 cwt. of Hope brush—I am not acquainted with these coals—and 323 tons of Tyrfilkin brush coal, so that there were four sorts of coal in the one and three in the other.

1483. (*Mr. Fenwick.*) Did you say that you paid 10 guineas per cent. insurance upon a vessel from the north to Coquimbo?—Yes, she discharged cargo in Dunkirk, and I sent to the agents in London to ask what they would get her insured for for the voyage, out and home, and the agents said I would have to pay the same as before, but when I came to settle it I had to pay 10 guineas on the balance of about 1,800*l.* on the voyage out only.

1484. What premium do you pay in loading small coal from Swansea?—I have not had many ships loading at Swansea, but I had an iron ship loaded with a cargo of iron in Newport in August last. She was launched at Stockton, and she came from Stockton to Newport with a half cargo of pig iron, and then she loaded a cargo of railway iron at Newport and a insured her for the voyage out to Talcahuano, and to come back to the United kingdom with nitrate at 100*s.* per cent.

1485. (*Mr. Icely.*) What description of coal is used for smelting purposes?—Bituminous coal—the small house coal.

1486. Is it the custom to screen it?—No.

1487. Is it what is called through and through coal?—It is not so large as through and through is as it comes from the pit. This coal would be coal out of which the large had been picked.

1488. It is all slack coal?—It was pretty nearly all slack coal that was shipped in those vessels.

1489. (*Mr. Abel.*) What is your reason for supposing that danger arises from the coal getting wet?—When coals get wet they get caked together, and becomes very hard, and a mass like that in the centre of the ship is a source of danger. It is the same with everything that is packed when wet; as it appears to me, it gets very hot after a time—a haystack will do so, or powder if stacked wet in the centre of a barrel, will generally get warm.

1490. You consider that coal containing iron pyrites, if it does not get wet, will not be liable to spontaneous combustion?—I do not think there is anything like the danger.

1491. You described the precautions that you would take to guard against explosions. Do you know any instance of explosion having occurred on a coal laden ship?—I have known several in Cardiff, but I have not inquired into the particulars. The mate of one ship, after the ship had been loaded, took a lighted candle into the hold and an explosion occurred. I do not know the particulars. The ship had been loaded four or six hours.

1492. Do you know the nature of the damage done by the explosion?—Part of the poop was blown away in that particular ship.

1493. Do you know of any instance in which fire followed the explosion?—No.

1494. (*Dr. Percy.*) I think you began by stating that personally you have no faith in ventilation?—Not for those smelting coals.

1495. Having stated that, you afterwards recommended a particular system of ventilation, did you not?—No; I stated the system I adopted, and I think in ships which I loaded at Liverpool, we were obliged to adopt that plan by the Board of Trade.

1496. You spoke of there being a great quantity of iron pyrites in smelting coal. How does the iron pyrites occur in smelting coal; is it in lumps or small particles?—In small particles.

1497. Did you see it distinctly?—We saw it in those samples before the court.

1498. Large heavy lumps of iron pyrites weighing half a pound?—No, it was distributed in the coal itself.

1499. Was any careful examination made to ascertain the quantity of iron pyrites?—Yes.

1500. You laid great stress on the importance of shipping this smelting coal dry. Have you known any cases of ships laden with smelting coal, shipped dry, taking fire afterwards?—I do not know of any.

1501. Do you know whether in those cases that have come under your own observation in which smelting coals had taken fire, the coals had been shipped when wet?—In all the cases it had been shipped wet.

1502. In all the cases of spontaneous combustion with which you are acquainted the coal had been shipped wet?—Yes; that is three.

1503. Do you know whether the same kind of smelting coal has sometimes fired and sometimes not fired?—I can only speak to the fact of my own ship being loaded by the same charterer in Swansea, the one time with wet coal and the other time with dry coal, and the time when she was shipped with wet coal she took fire.

The witness withdrew.

Mr. John Bladon examined.

Mr. J. Bladon.

1504. (*Chairman.*) What is your business?—That of a coal shipper at Newport.

1505. Have you been in that business for many years?—More than 25 years.

1506. Do you ship both large and small coal?—Yes, principally large coal.

1507. Will you tell us how coal is shipped generally at Newport?—It is shipped by means of a shoot

Mr. J. Bladon.

22 June 1875.

which receives it from the truck and carries it to the hold of the vessel into which it falls.

1508. Are large and small coals both shipped in the same way?—Precisely in the same way.

1509. Is the fall considerable from the end of the shoot to the bottom of the ship?—No, the shoot generally rests upon the edge of the hatchway; the fall depends upon the size of the ship; in small coasters you would not have a fall of more than 6 or 8 feet; in a large ship the fall would be greater, it would be from 8 to 18 or 20 feet.

1510. Various kinds of coal are shipped at Newport?—Yes.

1511. Will you describe them?—There are two special descriptions, one is called the steam coal, which is used for marine and locomotive purposes, and the other is called house coal. The two coals are essentially different in their nature; the steam coal is a coal that is considered to be free from sulphur and tolerably pure, and is therefore not much subject to spontaneous ignition. The house coal on the contrary is a coal which contains a large proportion of sulphur. It is also of a softer nature than the steam coal, and it contains a larger proportion of iron pyrites, and we consider it much more subject to ignition spontaneously, than the steam coal.

1512. Do you include under the general term of "house coal" smelting and smithy coal?—Perhaps it might comprise both coals, but we ship very little coal for smelting purposes at Newport; it is shipped principally, I believe, at Swansea.

1513. What classes of ships are generally employed to carry those different descriptions of coal?—The large steam coal which is generally screened at the colliery and then taken down to Newport and re-screened there for the purpose of taking out the small coal that may have been produced by the journey you ship in the vessels of almost all classes. Coasting ships such as go to ports on the English coast where a large quantity of steam coal often is sent, would vary from 100 or 150 tons to 300 tons; vessels going to and from foreign ports will vary between 300 tons, or less probably, and a couple of thousand tons.

1514. With regard to the house coals, where do they come from principally?—They come from the same district as the other coal, but they are generally found in the upper series; the coals nearest to the surface are house coals generally.

1515. What are their names?—One coal is well known under the name of Mynyddyslwyn, another house coal well known in the district is called the Cwmtilery and there are some other coals that go by other general names, but the two I have mentioned are the principal ones.

1516. Will you describe the ships that are generally used to carry those coals?—The ships usually employed to carry those coals are principally for the coast, say from 100 to 300 tons burthen; occasionally they are sent foreign, but not often.

1517. As you have little or no smelting coal shipped at Newport, the amount of house coal or even steam coal shipped for long distances is small with you?—Comparatively small as regards house coal, but the reverse as regards steam coal.

1518. You said that you considered the steam coal much less liable to spontaneous combustion than the house coal?—Yes, and for this reason, the steam coals contain much less sulphur than the others, and of the two they are harder and also purer. The house coals contain apparently as you look at them a considerable portion of sulphur; the sulphate of lime, as it is generally termed, is apparent upon the pieces as you see them in the truck.

1519. What is the colour of sulphate of lime?—Yellow. Sometimes it has a silvery appearance.

1520. Do you mean there is sulphate of lime as well as sulphate of iron?—Yes.

1521. You say that the cargoes of steam coal vary very much, some being as low as 300 tons. Which do you consider most subject to spontaneous combustion the larger or the smaller quantities?—The larger the quantity of coal you have in the mass the more subject it is to spontaneous combustion. But I have never heard of any cargoes of large well shipped steam coal ever taking fire.

1522. Do you then attribute spontaneous combustion to moisture principally?—I do.

1523. It is in your opinion most important that the coal should be shipped dry?—Yes, with the view of avoiding spontaneous combustion.

1524. Have there been numerous cases, so far as you know of combustion, from the coal having been shipped in a damp state?—I have not heard of many such cases. I remember within the last year or two hearing of the spontaneous combustion of some cargoes of coal that had been shipped at Newport, those coals were red ash house coal, not white ash, or steam coal. The coal was a kind called brush or small coal. When the coal is taken out of the mine and brought out to the surface, the large nobs are put into the truck and sent down to Newport and shipped, and the inferior coal is thrown aside and dealt with either in the character of brush coal or small coal.

1525. You are now speaking of house coal?—Yes.

1526. House coal in your opinion is liable to combustion, and it is a danger to be guarded against if it is shipped damp?—Yes.

1527. Is it possible to prevent its being shipped damp?—It would be possible if you had no regard to the expense, but when the coal is brought to bank, and the large coal is taken away, the small coal is generally cast aside and put into a heap and left there till required for sale, when it is sent to Newport. It generally gets pretty damp as it lies on the ground, and when it comes to Newport we can never say that it is in a perfectly dry state.

1528. Have you studied at all the question of ventilation?—Not a great deal. There are very few ships that we load at Newport which are ventilated. I have known cases in which large American ships have been loaded with large coal, when great care has been taken in the ventilation, but as as a rule the ships are not ventilated at all that are loaded at Newport.

1529. Do you consider that ventilation tends to prevent spontaneous combustion?—I should say it would. When you get a large heap of heated small coal at the colliery you find the heat is not on the surface, but in the centre of the mass.

1530. Do you think that by passing a continuous current of air through it spontaneous combustion would be checked or promoted?—That, perhaps, might depend on the fact whether it was shipped damp or not. If it were shipped damp of course the ventilation would scarcely affect the condition of it so much afterwards. If it were shipped dry I should say ventilation would have a tendency to prevent spontaneous combustion.

1531. If the coal were shipped damp you would be rather afraid that ventilation would be likely to promote the fire, whereas if the coal were shipped dry you would encourage ventilation?—Yes, I think I should.

1532. Does spontaneous combustion often take place at the pit?—Not often; occasionally it does. When you stack small coal in very large quantities combustion at the pit's mouth is not at all an uncommon occurrence.

1533. Have you known many instances of spontaneous combustion of coal which has been stacked after purchase?—Small coal is never stacked before shipment by purchasers. A few years since, the Royal Mail Company used to purchase large coal screened and fit for use from the Risca collieries, and store it to the extent of several thousands of tons, 5,000 I believe, at Newport. The heap, as near as my recollection will enable me to judge, would be from 7 to 10 feet high, and I never heard of its taking fire, or being considered liable to spontaneous combustion at all. But instances of purchasers storing any coal at the colliery or elsewhere prior to shipment are rare.

1534. You do not know of many instances of coal

Mr. J. Bladon.

22 June 1875.

taking fire spontaneously when in store or when stacked ?—I cannot speak to any such cases as having actually seen them myself.

1535. (*Mr. Vivian.*) Have you shipped any coal which has taken fire ?—I think not.

1536. (*Mr. Abel.*) Can you give any specific instances of spontaneous heating or actual taking fire of heaps of small coal ?—I am agent of the Ebbw Vale Company who possess many large collieries. The managers of those collieries have assured me that they had known not actual fires but heat to be generated in a heap of small coals which they prevented from actual firing by throwing the coal over a larger space.

1537. In all those cases the coal had become wet ?—Yes.

1538. Was it pyritical coal ? Was it house coal or steam coal ?—Steam coal. But all steam coals contain more or less pyrites as well as house coal but not to anything like the same extent.

1539. Did this heating in the heap of coal occur at any particular period of the year ?—I cannot say at what period it occurred. I think it occurred during the warm months, because the action of the sun and the wet upon the coals would be much more effective during the warm weather than in the cold weather.

1540. A large quantity of small coal is shipped, is not there ?—Yes.

1541. You do not remember any specific instances of fires with coal of that kind on board ship ?—No. We have sent and shipped from various works more than 200,000 tons in the course of a year.

1542. Are they all short voyages on which these ships sail ?—No, most of them go tolerably long voyages, the principal part of the coal being steam coal.

1543. Do some go to South America ?—Yes, and some to the West Indies and some to the East Indies.

1544. (*Dr. Percy.*) You said that some of the Ebbw vale coal when stacked in heaps was liable to take fire or to become hot ?—

1545. From what particular seams would that coal come ?—It would be small coal thrown together in a heap without regard to the particular seams from which it came.

1546. You cannot state whether the coal from one particular measure or seam is more likely to ignite spontaneously than the coal from another ?—I could not do that.

1547. As to patent fuel, have you known of a case of spontaneous combustion from patent fuel ?—I have not heard of any.

1548. (*Chairman.*) Is there any patent fuel shipped at Newport ?—No.

1549. (*Mr. Ferguson.*) Could you tell the depths of the heaps and the stacks which you say became heated or took fire ; is there any limit of depth at which combustion or heating would be preventible ?—I cannot give the depth at which heating would be likely to occur. I have seen heaps of coal 30 or 40 feet high.

1550. You said that large quantities were more likely to take fire than small quantities ?—Yes.

1551. But there is no limit of height at which you would draw the line ?—No, small quantities of small coal thrown together, say to a height of 6 or 8 feet, would not be liable to spontaneous combustion probably.

1552. (*Mr. Duncan.*) Did I rightly understand you to say that the 200,000 tons which you said you had shipped in the year were small coal ?—No, it was principally large.

1553. What proportion of it might be steam coal ?—I should say nineteen-twentieths.

1554. Properly screened steam coal ?—Yes.

1555. So that in speaking of the number of tons of coal that have gone in the year without accident, you were speaking principally of steam coal ?—Yes.

1556. And not of these house coals or the small slack which you think would take fire more readily ?—No ; in former days we shipped from a place called Abercarn considerable quantities of coals which contain this objectionable iron pyrites, but the shipment of them has been given up for several years that in giving a description of the two sorts I bear in mind what our workings were many years ago.

1557. I gather from what you say, that a shipper, like yourself, and those working the coals, are perfectly cognizant of the coals likely to generate spontaneous combustion ?—Yes, I think if you put the question to any shipper of coal, he would be able to tell you whether they were liable, more or less, to spontaneous combustion.

1558. They judge by their own observation ?—Yes, they judge from past experience.

1559. Seeing that we have had such a great number of cases of combustion on board ship lately, that is to say, in the years 1873 and 1874 as compared with what we had formerly, do you think it is likely that that increase may have arisen from the fact that when coals were very dear, a considerable quantity of those coals which used not to be shipped were put on board ship ?—I think not. I think that the shipment of small coals at Newport in large quantities is rather a new trade. I think that formerly the small coal shipped at Newport was generally considered smiths' coal and it was generally sent to the various ports round the coast, but the shipment of small coal for foreign districts is somewhat of a new trade. At Newport I know that I purchased for a London firm a cargo of 1,000 or 1,200 tons of this red ash, small, or brush coal, but that was an exception to our general trade. We are not in the habit of sending cargoes of small coal from Newport in ships of anything like that size.

1560. Taking you away from Newport, would it be a fair inference to draw, seeing that, as you have stated, coal shippers know that a particular kind of coal is likely to ignite and ought, therefore, not to be shipped for long voyages, that if there was a great pressure for steam coals, and high prices were being paid for them, it is possible that men may have been tempted to send away coals which they would not have sent away in former years ?—I hardly could go so far as to impute such an action to any of the coal shippers, there is no doubt that many fresh coals have come into the market within the last few years, but coal shippers have a pretty good knowledge of what they ship, they know pretty well whether the coals would be likely to take fire or not on the voyage.

1561. From your own knowledge you are not able to say whether it is possible that the cargoes were mixed sometimes when they were pressed for cargoes, that is to say, that steam coals were perhaps mixed with house coals which would not have been sent except under such pressure ?—I cannot say.

1562. (*Dr. Percy.*) I think you said that the Abercarn coals were likely to take fire ?—The steam coal I should say was not liable at all to take fire but the house coal which we formerly used to ship from Abercarn was liable to take fire.

1563. What was the name of the seam ?—We used to call it No. 1. We had another name for it in Welsh.

1564. You say that the shippers of coals generally know what kinds of coal are liable to spontaneous combustion ?—Yes.

1565. Can you state what kinds of coal in South Wales are particularly liable to ignition ?—I could scarcely do that. Reputation does give an evil name to many coals that are found in the neighbourhood of Swansea ; the intermediate coals lying between Swansea and Newport are generally supposed not to be so subject to spontaneous combustion as those at the far end, but I am not able to give you the names of the coals nor could I give you a general classification of them.

1566. Can you tell us how we can get the names of these coals ?—No ; the only suggestion I could make on that score would be to inquire from the inspectors of coal employed under the Admiralty. If they could not give it you I do not know anybody who could.

Mr. J. Bladon.

22 June 1875.

1567. (*Mr. Vivian.*) Whence do you derive the unfavourable reports with respect to certain coals which you have mentioned ?—You hear them occasionally.

1568. From whom have you heard them ?—From people generally.

1569. Is there not considerable competition between the Welsh ports, between Newport and Swansea for instance ?—Yes.

1570. That is a point you would be jealous upon, is it not, that is to say, house coals shipped from the neighbourhood of Swansea ?—I spoke without any reference to the question of jealousy ; everybody would as a matter of course ship as well as they could.

1571. Do you remember a deputation of Newport house coal owners coming down to Swansea to beg that the competition might be lessened ?—I do not.

1572. (*Mr. Duncan.*) In your experience are the coals shipped now in as short a time after they are raised from the bowels of the earth as they were formerly ?—There is no difference whatever in that respect.

1573. They are not brought to bank and laid out on the hill and exposed to the weather, and then shipped some time afterwards ?—In a case of necessity where you have no sale for your coals of course you put them on bank, but as a rule the coals are taken direct from the pit's mouth to the ship, and in the case of house coals more particularly, you would even stop your work for the time being and not raise the coal unless you had the opportunity of shipping it at once, for if it were deposited on the bank it would deteriorate in quality. The worker of the coal, as a rule, gets rid of his large coal as soon as it is landed, by putting it in the trucks, and sending it away.

1574. Practically your experience is that they are sent away and shipped just as rapidly after being raised at the present time as they were 10 or 15 years ago ?—Just as rapidly.

1575. (*Chairman.*) The suggestion that the coal being shipped in haste is the cause of the greater number of casualties from combustion or explosion which have occurred of late years has no foundation in your mind ?—None whatever.

1576. (*Mr. Abel.*) In what way does the coal deteriorate in quality by being kept ?—All coal, more or less, suffers by exposure to the sun and air.

1577. In what way ?—The softer kinds of coal perceptibly becomes softer ; it becomes disintegrated, and so much has that evil been felt that in most contracts made between the coalowners and the large steamship companies, they stipulate that they shall have fresh wrought coal.

1578. The general effect is a breaking up of the coal ; that is the principal deterioration ?—Yes, I think so ; for instance, if you put a quantity of coal on the ground, and it contains a certain per-centage of small, when you come to take it up you will find that the small coal has increased more *pro rata* than it ought to have done.

1579. Can you call to mind a shipment of any coal that has become small by exposure ?—I cannot. As a rule we are not shippers of small coal.

The witness withdrew.

Adjourned to Tuesday next at 12 o'clock.

Tuesday, 29th June 1875.

PRESENT :

THE RIGHT HONORABLE HUGH C. E. CHILDERS, M.P., IN THE CHAIR.

HENRY HUSSEY VIVIAN, Esq., M.P.
FREDERICK AUGUSTUS ABEL, Esq., F.R.S.
GEORGE DUNCAN, Esq.
JOHN FENWICK, Esq.
JOHN FERGUSON, Esq.
CHARLES ICELY, Esq.
JOHN PERCY, Esq., M.D., F.R.S.
J. M. CARMICHAEL, Esq., Secretary.

Captain GEORGE STEINSON examined.

Captain G. Steinson.

29 June 1875.

1580. (*Chairman.*) You are coal inspector for the Peninsular and Oriental Company at Newcastle ?—I am.

1581. For how long a time have you acted in that capacity ?—Over 14 years.

1582. You also act for some of the public Departments in the same capacity, I believe ?—Yes, for the Admiralty, for the India Council, for the Crown Colonies, and in 1864, 1865, and 1866, I inspected for the Egyptian Government but not since then.

1583. Do you inspect the whole of the coal shipped on the Tyne for those Departments ?—Yes, on the Tyne and the Wear, and at Seaham as well.

1584. Can you give the Commission any statistics as to the number of ships that have been loaded under your inspection ?—I have loaded for the Peninsular and Oriental Company 1,147 ships, for the Egyptian Government, 95, for the Admiralty, 96,for the India Council and for various private parties 170, making altogether 1,508 ships.

1585. What was about the average tonnage of coal carried in each ship ? — The average tonnage 1861 was 770 tons ; in 1862, 867 ; in 1863, 706; in 1864, 960 ; in 1865, 841 ; in 1866, 841 ; in 1867, 864 ; in 1868, 776 ; in 1869, 780 ; in 1870, 919 ; in 1871, 1,093½. I have not the average for the other years, but, I suppose, it would be from 1,000 to 1,100 tons. As regards the ships for the Egyptian Government, the average would be about 500 tons, and in the case of the general ships it would be 600 tons.

1586. That is the average amount of coal carried in each ship under your inspection ?—Yes.

1587. I observe that the average has increased pretty steadily ?—The average has increased pretty steadily, but I think it has increased more lately on account of so many steamers being loaded with coal.

1588. All those are ships carrying coal foreign ?—They are all carrying coal foreign, to Malta, Alexandria, Aden, Bombay, Galle, one or two to Calcutta, Singapore, Hong-Kong, and Yokohama.

1589. Those are for the Peninsular and Oriental ?—Yes.

1590. For the Admiralty, where would the coal be going ?—For the Admiralty, it would be principally going to the dockyards ; some would be going foreign.

1591. The coal for the Egyptian Government would be foreign, and the coal for the India Council would also be foreign ?—Yes.

1592. Have you had any cases of ships being burnt at sea from spontaneous combustion ?—I may first mention the case of one ship burnt in 1863 ; that was a very peculiar case. She was fitted with a ventilating shaft, not for coal, but for rice. The owner fixed a fan to keep a current of air over the rice at sea so as to keep the rice cool. That ship was burnt within 60 miles of Galle. I took notice of that casualty, and I made inquiry about it, and I found that the ship took out a cargo of coals from Newcastle, and she got aground somewhere on this coast, and the cargo was landed and was on shore a fortnight or three weeks, and I found that nearly all that time it rained, and the cargo was like muck when it was again put on board the ship.

Captain G. Steinson.

29 June 1875.

1593. Do you knew what the tonnage of that cargo was?—I do not.

1594. What was the name of that vessel?—The "Eliza Bulcke"; she was on a voyage from Newcastle to Galle.

1595. In that case the coal was landed, where?—Somewhere on this coast. I am only giving these particulars from second-hand information. I asked the captain about it, and the captain said that was the case. I know the cargo was put on shore, and I know it was very wet when it was again put on board.

1596. Was it your opinion that this fan contributed to the danger?—No, not at all. That was in 1863. Then I know of no other casualty having occurred in any vessels that I have had to do with till 1872 when the "Bernice" was burnt.

1597. What where the particulars of that case?—She loaded with 1,869 tons of Davison's West Hartley, in 1872. She was burnt very near Bombay. She was a very large wooden ship, and a very fine ship, but I have not any particulars about her ventilation. We did not think anything about ventilation or anything of the sort then.

1598. No particular precautions were taken as regards ventilation in her case?—She was ventilated. All Liverpool ships must be ventilated.

1599. How?—By shafts up and down each hatchway and fore and aft shafts alongside the keelson in the way Mr. Duncan's ships are ventilated.

1600. Have you any particulars with regard to the sort of weather it was when she was loaded?—

1601. Do you remember how the coal was put on board?—The coal was loaded into the ships by a lowering apparatus which we then used, but in loading Davison's West Hartley, they generally have to ship very quickly. There is not much accommodation for loading, and they have to ram the coal in as hard as they can.

1602. Would the coal fall any distance in loading?—It was loaded with a box at the end of the spout.

1603. The bottom of the box would open?—Yes.

1604. So that there would be no great fall for the coal?—There would be no great fall, but we could not often use that apparatus in the hatches.

1605. To what do you attribute that casualty?—I do not know how to account for it. There are many ways of accounting for it. It may have been from pyrites, or it may have been accidental.

1606. Was the coal double screened?—No; none of the coal is double screened.

1607. What sort of inspection would there be with a view to prevent the introduction of coal which was full of pyrites?—In those days they worked night and day, and even if I had been there at night, I could not have seen whether pieces of coal went in full of pyrites.

1608. So that coal containing pyrites might have passed, which in the daytime you would have rejected?—It might pass even in the daytime when I could not see it, because it goes so quickly over the spout.

1609. Are there no precautions taken at the pit's mouth to prevent coal containing much iron pyrites being shipped?—Yes, it is all screened there, but there may be big lumps of coal containing pyrites, the existence of which may not be discovered until the lumps are broken.

1610. You can assign no special cause for that casualty?—No.

1611. What was the next case?—The next was the "Oneiza."

1612. In what year?—December 1872. She was merely missing.

1613. Then the next?—The "Shalimar," she was a very fine new ship.

1614. In what year was that?—In 1873. She loaded 1,942 tons of steam coal, 100 tons of coke, and 148 tons of wall bottle nuts. She was never heard of. She was ventilated in the old-fashioned way with a large platform over the keel. She was rather crank, and her cargo was rather high on account of the platform. She was chock full.

1615. What was the next case?—The "Moorsfoot," an iron ship. She loaded in November 1873, with 1,664 tons of Howard's West Hartley.

1616. Was she burnt?—Yes, I have not the particulars of the case. I merely know that she was burnt. I saw the particulars in the paper.

1617. All you know of that case is that it was a cargo of Howard's West Hartley coal. Do you know anything about the particular pit or the particular seam it was from?—It is all from the same seam. They do not work a great deal of coal.

1618. All the coal of that name is practically the same coal?—Practically the same coal.

1619. Of the circumstances of that loss, you know nothing?—I know nothing of the circumstances.

1620. How was the ship loaded?—She was loaded by the apparatus. The lowering apparatus was used at that time, but the men did not handle it so well as they did formerly. They were beginning to be masters then. They have almost got to be masters now altogether. In that shipment the coal was very much broken.

1621. You think at that time the coal was not handled so well and so carefully as it used to be?—I think so.

1622. What was the next case?—The "Euxine." She was an old Peninsular and Oriental paddle-steamer turned into a sailing ship. She loaded in June 1864, with 2062 tons of Howard's West Hartley.

1623. Precisely the same coal?—Yes.

1624. Was she loaded in the same way?—Partly, not altogether; she was very high, and we had great difficulty in getting the cargo into the ship at all. The coal got very much broken in going in.

1625. It had to fall from a great height?—Yes, she was a very deep ship.

1626. Whose ship was she?—She belonged to somebody in Liverpool; I do not know the owner's name.

1627. Have you any further particulars about that case?—There was one thing that struck me about her; the captain had a quantity of ale on board as a speculation and this ale was stowed on the top of the coal. We know that sailors like ale, and some of them might have been at the ale, and in doing so might have set the ship on fire in the same way as, no doubt, the "Cospatrick" was burnt.

1628. Beyond that you know nothing of the particulars of that case?—No.

1629. What was the next?—The "Oliver Cromwell," a North-American built ship, and then there was the "Calcutta," both belonging to the same owner and both loaded about the same time; in fact, the "Euxine," the "Calcutta," the "Oliver Cromwell," and another ship called the "Cora," were all loaded together.

1630. With what coal?—The same coal, Howard's West Hartley.

1631. From the same pit and the same seam?—From the same pit and the same seam.

1632. What information have you about those vessels?—The "Oliver Cromwell" was ventilated. The captain came and asked me how I wanted the coal ventilated, and I said, "I do not want the coal "ventilated at all, it is no business of mine." On that he said he was obliged to ventilate by the charterparty. I said, "Then ventilate according to the "charterparty but, as far as my own opinion goes, I "would not ventilate at all." He further said, "The owners say she must be ventilated." "Then," I said, "ventilate according to the owners' instructions." So he did ventilate according to the owners' instructions, with shafts up and down each hatchway, connected with fore and aft shafts. The "Oliver Cromwell," the "Calcutta," and the "Euxine," were all ventilated, but the "Cora" was not ventilated.

1633. Were all those vessels lost?—The three that were ventilated were lost, that is to say, the "Oliver Cromwell," the "Calcutta," and the "Euxine;" the "Cora" which was not ventilated was not lost. The

Captain G. Steinson.

29 June 1875.

captain said he did not want any through system of ventilation, and I gave him my ideas of ventilation and he said those were his own ideas about it, that is to say, plenty of ventilation through the deck, plenty of ventilation on the surface of the coal, but no ventilation right through it.

1634. Do you attribute the loss of the other three ships to the fact of their being unnecessarily ventilated?—I do; the "Cora" was loaded along with those other three with the same coal, sometimes one ship was taking in coal and sometimes the other; they got identically the same coal.

1635. Nothing happened to the "Cora?"—No; in the case of the "Cora," when she was shipping her cargo there was a heavy thunderstorm, and the rain came down in torrents and she got a wet cargo. The other ships had dry cargoes.

1636. Nevertheless, the three ships which had dry cargoes and which were ventilated, were lost, whereas the "Cora" was saved?—Yes; the captain was a shrewd American, and he and I put our heads together, and after having a conversation about it he decided not to ventilate her at all.

1637. What other cases have you?—The next ship was the "Broughty Castle;" she is missing; she was an iron ship belonging to Dundee.

1638. Where was she loaded?—She was loaded in the Tyne in December 1873 with West Hartley main; she was a splendid iron ship.

1639. Nothing has been heard of her?—No.

1640. Was her coal wet when it was put on board?—I would not be quite sure. She was loaded at Christmas time; she was not loaded with the lowering apparatus.

1641. Was she loaded from the tips?—Yes.

1642. Was the coal from any particular seam?—It was splendid coal, West Hartley Main, the Low main coal.

1643. What is the next case?—The "Ontario." I believe she took fire; she was not burnt altogether; she was loaded in August last year.

1644. For what port was she bound?—Bombay, she was carrying out coals for the Peninsular and Oriental Steamship Company; she took fire in Bombay harbour, or somewhere near the harbour.

1645. Have you any other case?—The "Poco hontas" which was loaded for the Indian Council in June 1874.

1646. She was loaded with what coal?—Hastings Hartley, 1,580 tons. She was an American wooden vessel.

1647. Can you give us any particulars about her loading? was she loaded from the tip?—Yes, she was not loaded with the lowering apparatus, she was loaded by another plan which we sometimes adopt. We lay a flat platform upon the lower beams, and then the coal lies upon this platform and falls easily down to the hold; there is very little fall by adopting that plan. We make the fall as little as possible.

1648. What happened to that ship?—She was burnt at sea.

1649. Was she ventilated?—She was ventilated with shafts up and down. I cannot say whether fore and aft. I have a suspicion about the cause of that casualty from what I saw myself when the ship was loading. The captain was always going about with a pipe and lighting it with matches and throwing them down, and I said to him, Do not you think that that is rather dangerous?

1650. What is the next case?—Then there was the "Sidra," a steamer, she is missing, she was bound for the Mediterranean, and she carried 1,850 tons of Carr's Hartley. There is nothing to lead to the conclusion that she was burnt. I fancy she has gone down.

1651. Do you know whether she was fitted with water ballast?—Yes, I believe she had water ballast.

1652. You have no reason to think she was lost by fire?—No.

1653. She is a missing coal ship?—Yes.

1654. Will you mention any other case that you are acquainted with?—The "Indian Empire" one of Mr. Duncan's ships, she loaded a cargo of Howard's West Hartley, in 1873. I have not the particulars of whether that case, so as to be able to say she was burnt altogether or not.

1655. How many of the cases you have given us were missing, and how many were burnt at sea?—There were seven ships burnt at sea, and including the "Ontario" there were eight. Those are ships that are said to have been burnt at sea, that is all I know about them.

1656. You cannot state positively that those seven were cases of spontaneous combustion?—They call them cases of spontaneous combustion. They were burnt at sea, that is all I know about them.

1657. Summing up the number of cases you have given us there are eight cases of coal ships burnt at sea, or in harbour, after arrival, four cases of missing ships, including the steamer?—Yes.

1658. Then you have known a few more cases of accidental fire which were clearly not cases of spontaneous combustion?—Yes, three cases in the Northumberland Dock, one ship took fire in the sail room, that was the "Ettrick Dale," and she was very nearly burnt in the dock when she was under the spout. Another vessel took fire at night from some cause or another, the deck was burnt, and some of the burning timbers fell down and fired the coal. Another vessel took fire when the boys were taking in stores after she was loaded, and no doubt they caused the fire.

1659. Those three cases are altogether outside those you have stated before?—Yes.

1660. In none of those cases was the fire spontaneous?—No.

1661. Those eight cases of ships certainly burnt, and four cases of missing ships are out of how many altogether?—Out of 1,510 ships.

1662. Since what time?—Since 1861. In fact those have all been since 1872 except one case.

1663. Since 1872 you have had seven cases of ships lost by fire at sea, or in Bombay harbour, and three cases of ships lost at sea, cause unknown, but which may have been from fire?—Yes, the "Oneiza," the "Shalimar," and the "Broughty Castle."

1664. That is out of how many that you have superintended the loading of since 1872?—215.

1665. So that between 1861 and 1872 you had one, only one decided case of a ship lost by fire out of about 1,300 ships, whereas since 1872 you have had seven cases, and three possible cases out of 215?—That is so.

1666. That indicates therefore a very grave increase in the number of casualties from fire during the last two or three years?—Yes, but I do not believe they were all owing to spontaneous combustion. For instance, in the case of the "Calcutta" the other day, I looked over a list of the crew and there were not two of one nation, they were all mixed up together; I should draw from that the inference that there would be constant rows on board the ship; that they would be always quarrelling.

1667. And you think the ship may have been fired?—I think it not at all impossible that the ship may have been fired. I happened to see a list of the crew and I at once formed that opinion from looking at the list.

1668. You spoke of the charterparties in certain cases requiring ventilation, and you told us that you said to a captain if you are bound to ventilate, ventilate accordingly, but in a case where it was not stipulated that the ship should be ventilated, you talked the matter over with the captain, who was an American, and he arranged that the ship should be ventilated upon your principle, and you told us that in that case no casualty occurred. Will you be kind enough first of all to explain to the Commission whether in those cases where ventilation was required it was required by the Peninsular and Oriental Company or whether it was a matter of stipulation between the owners and the charterers?—The charterparty says that the ship is to be ventilated.

1669. Would the Peninsular and Oriental Company

Captain G. Steinson.

29 June 1875.

be a party to the charterparty?—The Peninsular and Oriental Company would be indirectly a party to the charterparty, but the chartering brokers make the charterparty. I do not know whether the Peninsular and Oriental Company insist upon ventilation or not.

1670. Do the Peninsular and Oriental Company charter ships directly, or do they arrange with intervening people who charter from the owners?—The ships are chartered through intervening people.

1671. So that the Peninsular and Oriental Company themselves do not require any conditions as to the ventilation?—I do not know whether they insist upon such conditions being put into the charter.

1672. At any rate you as representing them on the spot know nothing about any conditions as to ventilation?—No, I have no intructions about it.

1673. What is your opinion about the ventilation of ships carrying north country coal?—The other day a very large iron ship loaded with coal, and the owners were very anxious about ventilation, and they asked me about it. The ship belonged to Messrs. Hall Brothers, of Newcastle. I said that I had no intructions about ventilation. I said, "It does not seem to be decided " yet whether ventilation has a good or a bad effect, " but my own opinion is that it has a bad effect, " but I have nothing to say about the matter." Mr. Hall said, "I wish you would write to the Peninsular " and Oriental Company about it." So I wrote to the Peninsular and Oriental Company about it and said that the owners were very anxious to know what was to be done about the ventilation. They wrote back to say, "We leave it to yourself and the owners to make " the best arrangement you can." I went and saw Mr. Hall and he said, "What do you propose?" I told him what I would do would be this, I would have no through ventilation at all, but I would have a small shaft in each hatchway to let the thermometer down, so that the captain should not be surprised by flames coming up the main-hatch. He said he was not a practical man, but what I suggested was what he thought a very proper thing, the ship was newly-built and it has great square ventilators, three or four feet square, and ventilators fore and aft alongside the keelson full of holes. So the owners cut off all this ventilation, blocked up all the holes, stopped the connexion with fore and aft, and merely put small pipes down for the lowering the thermometers, and she took in 2,478 tons and arrived at Hong Kong all right.

1674. That opinion which you gave to Mr. Hall expressed your judgment that north country coal had better not be ventilated?—That is my opinion, that it had better not be ventilated.

1675. All you require is to take the hatches off?—I would have ventilation through the deck, as much open space through the deck as possible.

1676. To carry the gases off?—Yes.

1677. So far as regards ventilating the interior of the coal, you think it mischievous rather than otherwise?—It would not do the coal any harm if there were no pyrites in it, but if there is any pyrites present, it is almost sure to take fire, if the air gets at it.

1678. You would endeavour to keep the air from the interior of the coal, and only keep the exterior clear of gas?—Yes; I would ventilate the upper surface of the coal, no gas goes below, it all rises.

1679. Do you know anything of South Wales coal?—No. There is one case I forgot to mention. A foreign ship was missing some years ago, which was loaded partly with steam coal and partly with gas coal. I had to do with part of her loading. That gas coal was put in very wet. That was some years ago.

1680. You had not the entire responsibility of inspecting that?—No, I had nothing to do with the gas coal. She was so badly contrived that I would not let any more steam coal go into the after part of the ship, and so they filled her up with gas coal.

1681. As to the methods of loading, you have described the method of lowering adopted by you in the case of shipments for the Peninsular and Oriental Company, do you approve of that mode of loading?—I like it very much, but the men will not work it.

1682. Not at all?—No.

1683. How long is it since they have refused to work it?—This last two years.

1684. Is the coal now entirely loaded from tips?—No, I have a better plan than that, which I mentioned, by which you can do without the men at all. You lay a large platform of wood on the lower beams, and then the coal falls there first and forms a cone in the hatchway, then the coal slips off that cone, and then it has only the depth of the lower hold to fall. I have loaded a large ship in that way. It is better than the other way, and you do not have to depend on the men.

1685. Is that the way in which you are now loading all coal?—Yes, we try to save breakage as much as we can.

1686. When did you begin to load in that mode?—Partly ever since I have been on the Tyne, when we could not adopt the other plan.

1687. What is the greatest fall where you adopt that mode of loading?—It depends on the depth of the ship. We had a ship the other day which had a 20-feet fall after the coal reached this platform. Her depth of hold was about 28 feet; she was a very large ship.

1688. When you say the men will not work the other mode of loading, what do you mean?—The men are masters now and they decline to do it.

1689. Why?—Because it is so much trouble.

1690. (*Mr. Duncan.*) What kind of coal was loaded on board that ship of Messrs. Hall?—Partly Bower's West Hartley and partly Bebside.

1691. That ship arrived at her destination quite safely?—Yes.

1692. And she had no ventilation whatever?—No; only pipes through each hatchway, by which to let down the thermometer. There were ventilators fore and aft alongside the keelson, but Mr. Hall had them all blocked up, and the connexion with the upright ventilators was all cut away, so that they were not ventilators at all. He blocked up the bottom of them.

1693. You had two or three large ships of mine last year?—Yes.

1694. They were ventilated, were they not?—They were ventilated.

1695. And they arrived safely at their destination?—Yes; it does not follow because they arrived safely that it was due to their ventilation. There may not have been any brassy coals in their cargoes.

1696. Is it your judgment that I was not wise in having the ships ventilated?—Some of your ships have taken fire.

1697. And those were ventilated?—Perhaps not, but ships that have been ventilated have taken fire. I argued the point with Mr. Stewart about ventilation, but he persisted in having the ships ventilated.

1698. Though you thought they would be better without it?—Yes. It is a curious thing that none of the north country ships that I have had to do with that have not been ventilated have been burnt. I was talking to an old captain, who told me that he had never had a casualty happen to a ship except in one case, and that was the only time he ever ventilated the ship, and he said he would not go to sea in a ventilated ship.

1699. Your opinion is that ventilation does harm rather than good?—Yes, with north country coal; you cannot have coal very well without pyrites in it; if you could get coal without pyrites in it you might ventilate as much as you liked.

1700. (*Mr. Ferguson.*) In the case of the American ship which went out safe, did I rightly understand you to say that the coal was wet when it was loaded?—Yes.

1701. So that though the coal was wet, and though the ship was not ventilated, the ship arrived safely at her destination?—Yes, a portion of the cargo was very wet.

1702. In the case of the other three ships that were

Captain G. Steinson.

29 June 1875.

ventilated, and which were burnt, was their coal loaded in dry weather or wet ?—In dry weather; there may have been just a thunderstorm.

1703. In the case of the ship which you spoke of last, where you advised the captain to do away with the ventilation, was her coal shipped wet or dry ?—Dry, I believe.

1704. You say the owners blocked up the ventilators ?—They cut off the bottom and filled them up at the bottom so that they did not act any longer as ventilators.

1705. You approve of ventilation from the upper deck upwards ?—Yes, above the coals.

1706. (*Mr. Duncan.*) Do you think the coals were as well cleaned during 1873 and 1874, when there were so many cases of burning, as they were formerly ?—No, I do not think they were.

1707. You do not think they were so freed from lumps of coal containing appearances of pyrites ?—I do not think they were so well cleaned.

1708. Do you think they are as well screened now as they used to be ?—The screens are much about the same; the screens are a little narrower.

1709. Do you think that the fact of coals having greatly risen in price would be a considerable inducement to the colliery owner to send coals less carefully screened than formerly ?—I do not think that.

1710. You think in the main they pass through the same process as formerly ?—Yes, there is one difference which I believe the Mines Regulation Act has had something to do with. Formerly the coals passed over the screens and fell into wagons, and all brasses were picked out before the coal went into the wagon, but if a piece happened to fall into the wagon there was a boy in the wagon to pick out any little bit; perhaps a lump would break and show a brassy appearance, and the boy could pick out the brasses and put them on one side. Now there are no boys there. I think the Mines Regulation Act may have made them afraid to put boys to work at that; at all events the boys are not there now as they used to be, so that if a piece of brassy coal fell into the wagon it would be likely to remain there.

1711. There was such a great demand for coals when the price was so high that there was no difficulty in disposing of almost any coals ?—No.

1712. (*Mr. Ferguson.*) Would you dispense with ventilation for all coals, or only for pyritical coal ?—I can only give an opinion about north country coals.

1713. (*Dr. Percy.*) I did not quite understand what you said about the rice-laden ship; was she laden partly with coal ?—No. She was a rice ship; she brought rice home.

1714. You spoke about a fan in that ship; do you know whether that fan would be effectual in preventing the heating of rice ?—It would keep a cool current of air on the top of the rice.

1715. Is rice liable to spontaneous ignition ?—It heats very much and spoils.

1716. The cooling of it by a draught of air prevents that ?—It is supposed to do so.

1717. Do you know of your own personal knowledge whether it does ?—No.

1718. The "Euxine" was a ship that took fire ?—Yes.

1719. And the coal which was shipped on board of her was dropped a long way down?—Yes.

1720. There would be a quantity of small coal accumulated about the spot where it fell ?—Yes.

1721. Was any examination made with respect to the particular place where the great fall occurred ?—I cannot tell you that. Falling a great distance very often exposes brasses which would be covered up otherwise.

1722. In another ship which took fire I understand you to say that the captain was generally to be seen smoking furiously ?—He was always trying to smoke, but his pipe never seemed to light.

1723. A fire occurred in that ship ?—Yes.

1724. Have you any evidence to show that the fire took place in the coal and not elsewhere ?—No, I merely know what I saw in the papers about it.

1725. You say that from 1872 numerous cases of what was supposed to be spontaneous ignition have occurred, has there been any alteration in the mode of loading, or in the ventilation, or in the kind of coals shipped between 1872 and the present time ?—There was a little difference in the loading in the case of those ships. An accident happened at the spout where Howard's West Hartley coal were being shipped, and we had to get the coal in anyhow we could for a while on account of that accident. Several ships were on at the time.

1726. Do you think the effect of that probably was to produce more small coal ?—Yes, I reported so at the time. The coal appeared to be very much broken.

1727. The kind of coal was the same ?—Yes.

1728. You said that between 1861 and 1872 there were very few cases ?—Yes.

1729. Is it certain that the same kind of coal was shipped in that former period as in the period when the numerous cases occurred ?—It was the same coal exactly.

1730. (*Mr. Abel.*) You ascribe the heating of coal on board ship entirely to the presence of pyrites ?—The firing of it; it will heat, but not take fire without pyrites.

1731. Will you tell the Commissioners a little more explicitly on what you base your opinion as to the undesirability of ventilation ?—I believe if coal containing pyrites is heated and a great pressure is put upon it, it merely wants fresh air to make it ignite. I submitted that opinion to a chemist at Newcastle, Mr. Glover, and he said it was a great chemical fact. That was my own opinion, and I got it confirmed by him as a chemist.

1732. You do not object to the circulation of cold air over the coal ?—No.

1733. Therefore, as far as that goes, you would consider ventilation to be advantageous ?—Yes, above the coal to let the gas escape.

1734. Have you ever known a case of explosion on board a coal-laden ship ?—Not with our north country coal. There is not sufficient gas in the coal to cause explosion.

1735. (*Mr. Icely.*) Were ships generally ventilated prior to 1872 ?—Many ships were ventilated, and the ventilators were generally full of coal before the ship was fully loaded. We could not get the ships loaded for the ventilators, though the ventilators were there they were full of coal. That was what first drew my attention to it. They were of no use because they were full of coal, therefore they did not seem to be necessary.

1736. You mentioned that the boys who formerly picked out the pieces of brassy coal no longer do so ?—Yes.

1737. At what date was the practice of employing boys to pick out the brassy pieces of coal discontinued ?—It has gradually been discontinued since the Mines Regulation Act came into force.

1738. When did the Mines Regulation Act come into force ?—Within the last two or three years.

1739. Those accidents have been more rife since the cleaning of the coal has been neglected ?—The men have been getting more careless in every way since then; since they got the big wages they have been getting more careless.

1740. Are you of opinion that the coal has been much more carelessly cleaned since 1872 than previously ?—I will not say much more carelessly; it is not so carefully cleaned.

1741. Have the places of these boys been filled by anyone else ?—There is a screener at each side of the screen; he is supposed to pick out the brasses.

1742. Did the boys supplement those men ?—The boys supplemented those men.

1743. Therefore there was a double check, now there is only a single one ?—Only a single one. I do not see much more brasses going in than formerly, and

Captain G. Steinson.

29 June 1875.

I have watched the coal sometimes over 12 hours at the end of the spout.

1744. Do you inspect the whole of the cargo?—I see as much as I possibly can. I cannot see the whole of it.

1745. Sometimes you have two or three ships loading at the same time?—Yes, but I have assistants.

1746. You have authority to reject dirty coal?—Yes, and I order it to be taken out of the ship sometimes when it is in.

1747. Is it the custom in ships which you load or inspect the loading of, for the trimmers to fill the coal right up to the square of the hatchway?—Yes.

1748. Is the square of the hatchway filled with small coal or large coal?—The small coal lies in the hatchway, and before we finish we separate the small all round and put a wagon or two of big coal in the hatchway.

1749. The small is not taken out?—No.

1750. Therefore, it in a measure seals the hatchway; it takes the place of the hatch when the hatch is off?—Before the hatchway is filled up they cut through on each side, and we tip a wagon or two in the hatchway at last so as to allow a circulation of air. In the case of a ship loading in Sunderland some years ago there was a lot of small coal being shipped the last thing into the hatchway, and I wanted the trimmers to take the small out of the hatchway, but they would not take it out.

1751. (*Mr. Vivian.*) Have you heard that there is a great difficulty in working the coal clean underground owing to the men declining to obey the orders of the overlooker?—No, I have not heard so.

1752. You said you had not remarked that there were more brasses in the coal now than formerly?—No, I think not.

1753. If that is so, to what do you attribute the increase in the number of cases of spontaneous combustion in coal-laden ships?—The brasses might be there without my seeing them; a big piece of coal will contain a brass inside, and you will not see it till it is broken.

1754. Are you aware that brasses exist chiefly in certain portions of the seam of coal?—They seem to be all over the coal. You cannot see the brass till the piece of coal is broken.

1755. You spoke of the difficulty which you have had with the trimmers. When did that difficulty begin?—There was a strike some years ago; they used to work night and day, and they struck for shorter hours. I think about two or three years ago.

1756. At the time when labour was so scarce?—Yes.

1757. Did they carry their point?—Yes; and instead of working night and day they knocked off at 5 o'clock.

1758. Since that time the moral effect of their having gained their object has made them less amenable to discipline?—They are decent men enough, but they will not work long hours now.

1759. Was the working the long hours the cause of the coal being better put on board ship?—No, the first part of the cargo was generally put in in daylight.

1760. You would not attribute the difference to the cessation from working long hours?—No.

1761. You attribute it to the negligence of the men, and their indisposition to work?—They will not work the lowering apparatus.

1762. Because it gives them trouble?—Yes.

1763. Is not that a question of wages; would not you be able to induce them to work it if you gave them more wages?—They have told me sometimes they would not work it if I gave them the ship and the cargo too.

1764. There is a general indisposition to put themselves to any trouble?—That is it.

1765. That has arisen since the strike, two years ago?—They always objected to work this thing; they used to call it the devil; they consider it is a nasty thing to work.

1766. They used to work it?—Yes.

1767. Since the strike, when they got the better of their masters, they have declined to work that machine?—Yes.

1768. What was the objection they had to this machine?—There is a good deal of care required in handling it; one or two men got their fingers snapped off in working it; they have a good deal of trouble in working it.

1769. Are any more wages paid for working it?—The men were paid 10*s.* a ship-load more, but that was stopped.

1770. Do you think if the men had been properly paid for working it they would have declined to work it?—Yes. I do not think any money would have induced them to work it.

1771. It is dangerous to work it?—There is little danger about it.

1772. Could not that danger be obviated by better mechanical arrangements?—Yes; the thing was never properly fitted.

1773. The fault seems to lie really with the shippers?—The colliery people ought to fit proper things, but they will not take any trouble about it.

1774. You would rather blame the colliery people than the men?—They are both to blame, I think; the men do not like anything that gives them more trouble, and the colliery people do not seem to take much trouble about it.

1775. It is to the advantage of the colliery owner to ship coals in as good a condition as possible, is it not?—They do not seem to think so; they charge the same price for coal whether badly shipped or well shipped.

1776. You give a preference to coal which is well shipped over coal which is badly shipped, do you not?—We want the coal as good as we can get it. I am supposed to look after it, and I do the best I can.

1777. Supposing one colliery shipped coal well, and another colliery shipped coal badly, you would report that to your principals, would you not?—Yes.

1778. Have you done so?—Frequently.

1779. And still it has produced no effect?—Yes, it has produced some effect; we cannot always get the coal we want; we must take the coals we can get.

1780. At present there being no such great demand, you can pick and choose?—What I mean is this, supposing we have got a ship to load with coal, and we have only got so many days to load her in, and suppose we cannot get the coal we want, we have to get some other coal.

1781. The fault seems to be a very divided one?—Yes, it is.

1782. (*Chairman.*) I suppose when the coal fever has thoroughly subsided, a little more attention is likely to be paid to improvements in modes of loading?—I do not know about that. The fever has subsided in the north now I should think.

1783. Coal owners are still hoping for a rise in price?—The next thing should be a fall I think.

1784. Do not you think if it is found that this method of shipment is really advantageous, and that the men are unwilling to adopt it from the danger arising from it, that some exertion will be made to improve it?—For my own part, I prefer this new plan to which I have referred, when I can get plenty of planks with which to make a platform.

1785. Is that plan adopted by anyone but yourself?—No, I do not think any one takes any trouble about the matter except myself.

1786. The Peninsular and Oriental Company stand alone in trying to ensure as far as possible the proper shipment of coal?—There is no one else that I see taking any trouble about it.

1787. Do your instructions from your principles at all point to the desirability of so shipping coals as to avoid the danger of spontaneous combustion?—There is nothing about spontaneous combustion in my instructions.

Captain G. Steinson.

29 June 1875.

1788. It is not a danger to which your attention has been called ?—No, I have had very little instructions about it.

1789. Your instructions are to see that good coal is shipped rather than to consider what may happen during its transportation ?—I never heard anything about spontaneous combustion till lately when these ships took fire, and then they wrote to me to give them my opinion upon the matter, and I wrote to them upon the subject.

1790. They being now in possession of your opinion upon the subject, they have not issued any particular instructions ?—No.

1791. You were commander of a ship yourself, I think ?—Yes.

1792. Did you ever command a ship laden with coals ?—When I first joined the company, I took a ship up the Red Sea, and I happened to fall in with the log the other day in which I kept a record of the temperature as shown by the thermometer in the cabin, in the fore-hold, and in the aft-hold.

1793. When you commanded a coal-laden ship, you were very careful to observe the temperature every day ?—Yes, every day.

1794. Is it the custom now in coal-laden ships to observe the temperature from day to day ?—No, I spoke to some captains of ships about carrying a thermometer with them, and they said it would be a very expensive thing, but a thermometer only costs a couple of shillings, and they also said it would be an expensive thing to put down a tube, but that would not cost much.

1795. Did you record the temperature in the log ?—Yes, I find in this log which I kept I have got the latitude and longitude, the course of the wind, the state of the weather, and the state of the temperature according to the thermometer in the cabin, in the fore-hold, and in the after-hold.

1796. Would you think it desirable in coal-laden ships that a note should be made in the log daily of the temperature of the coal ?—Yes, I think so.

1797. And that that should be required by law ?—I think so. When I wrote to the company, and said I had induced the owners instead of having ventilators to put down a thermometer, they said, in reply, that they quite approved of it, and they would like if I could induce the owners of all the ships to do the same thing.

1798. (*Mr. Abel.*) You carefully noted the temperature at different times ?—I marked it every day at noon.

1799. What would you have considered an indication of danger in connexion with those observations of the temperature ?—If the temperature was gradually rising, I should think the coal was heating.

1800. What steps were you prepared to take in the event of there being indications of danger ?—I should let in water, or do something of that sort.

1801. You had no definite measures laid down beforehand that you would have taken ?—A sailor is always prepared for difficulties; if he is not, he is not fit to be a sailor.

1802. You could not tell the precise nature of the means you would have adopted ?—I was never beaten yet.

1803. (*Mr. Fenwick.*) It is chiefly or entirely Hartley coals that you have inspected ?—Yes; I have shipped other coal for the dockyards, that is only for short distances.

1804. Speaking of Hartley coals, they are all from the same seam, are they not ?—No; there is the Low Main coal and the Yard seam.

1805. Is there any marked difference between those two seams ?—A considerable difference. Before they come to work the Yard seam the Low Main is generally pretty well worked out; the coal is crushed out, you can tell the difference because there is a great deal of pillar coal in it.

1806. Is one seam more liable than another to contain pyrites ?—I could not say that.

The witness withdrew.

Mr. J. Glover.

MR. JOHN GLOVER examined.

1807. (*Chairman.*) You are a chemical manufacturer at Newcastle ?—Yes.

1808. And a member of the Chamber of Commerce of Newcastle ?—Yes.

1809. You have given your attention to the subject which this Commission was appointed to inquire into ?—I have.

1810. Will you tell us what led you to turn your attention to the subject, and what opportunities you have had for forming an opinion upon it ?—My attention was more particularly directed to it from reading the lamentable accounts that appeared in the newspapers from time to time of the serious loss both of life and property from such occurrences, but my attention had been previously directed to the question as a chemical manufacturer storing large quantities of coal. I conversed with several of my friends upon the matter from time to time and from the chemical education I had received I formed certain opinions. Those were deemed to be sufficiently cogent to lead the Northern Maritime Insurance Association of Newcastle to write to me asking my opinion as to the causes of fire in coal ships, and they forwarded to me from time to time certain protests which they received from captains giving their accounts of fires, and I wrote certain letters on the subject. Our local authorities asked me if I had any objection to my letters being sent either to the Shipping Gazette or to the Liverpool Insurance offices. I said, on the contrary, I was anxious that they should be made use of in any way that was desired. The result was my being requested to attend this Commission.

1811. Will you tell the Commission what the nature of that correspondence was ?—The Secretary of the Maritime Insurance Association asked my opinion of the effect of ventilation on coal-laden ships, and, after due consideration, I came to the conclusion that ventilation ought rather to be avoided than sought for. I then suggested to them that if they could cover the surface of the coal with small coal and hammer it down as close as possible so as to keep the air from the cargo, it would be an advantage instead of putting in trunks to carry air into the centre of the cargo. I may mention that ventilation would, in my opinion, be advantageous if it could be applied to the whole bulk of the cargo, that is to say, if it could stream up through the coal as water would stream through a filter; but that desirable state of things cannot be practically arrived at. Therefore, instead of taking the air into the coal I would endeavour to keep it out, because, granted that spontaneous combustion was imminent in the cargo, an abundant supply of air would tend to fan the flame.

1812. You are speaking of north country coal ?—I am speaking of north country coal. That is the only coal I have had experience with.

1813. You have not studied the question in connexion with Welsh steam coal ?—Not at all.

1814. It is only with reference to north country coal that you are giving your evidence ?—Yes.

1815. What do you consider to be the cause of spontaneous combustion in north country coal ?—In my opinion the principal cause of combustion is the presence of bisulphide of iron in the form of coal brasses with a little moisture in the coal. Dr. Percy in one of the tables in his recent work on fuel, draws attention to the fact of a coal containing a much larger amount of sulphur than another not being so spontaneously ignitable as that other coal. If I had had time I would have produced specimens to the Commission showing that brasses (or pyrites) exists in coal in two or three distinct forms. It exists in the massive

Mr. J. Glover.

29 June 1875.

form, and it exists also in the form of very fine filaments, almost microscopically fine, those filaments being combined with filaments of equally finely-divided coaly matter. We have a condition in that latter case which we have not in the former, and though there might be more sulphur in the former case than in the latter the coal in the latter case would be more liable to ignite spontaneously on account of the finely-divided structure of the coal and the brasses. Dr. Percy also mentions in his valuable work on fuel, that coal very finely divided will spontaneously ignite. There is little doubt that it will, if you have the necessary condition of quantity of that finely-divided coal. I can scarcely imagine that there could be that condition of quantity of finely-divided coal in a coal cargo. Those are two conditions; and then there is another condition: all our coal contains a quantity of shale, and that shale contains a quantity of a very volatile and highly bituminous substance; it may be in the form of paraffin or some of the compounds that yield paraffin. I have obtained from shale from 12 to 15 parts of volatile matter of a highly inflammable character. By the table in Dr. Percy's book it appears that the most highly inflammable coal is schistose coal, that is, coal containing schist, and I would throw out a suggestion to the Commission that probably the quantity of schist in coal may have a great deal to do do with spontaneous combustion. Certainly the bisulphide of iron has to do with it, of that there can be no question, and as regards the second condition, when a gentleman like Dr. Percy is satisfied with the result of the experiments of continental chemists which went to show that finely divided coal would also spontaneously ignite I think we may accept it as a fact.

1816. You divide the conditions of spontaneous ignition of coal into three classes?—Yes.

1817. What remedy would you propose to apply?—Speaking of spontaneous combustion, and not of explosion, the remedy I would propose would be, in the first place, that there should be inserted into the coal, through the deck, if possible, a number of $\frac{3}{4}$-inch iron gas pipes placed 8 or 9 feet apart, down which gas pipes should be lowered at fixed intervals a self-registering thermometer. Every day the captain should enter in his log the temperature of each of those pipes, and if he found the temperature rising in any of them, he should be prepared with an apparatus of which I submit a drawing to the Commission (*handing it in*): an apparatus consisting of a wooden cistern with a false bottom, into which you would put chalk, and upon that you would pour hydrochloric acid. I have made some calculations with the detail of which I need not trouble you, but I find that taking, what is called in our district round coal, that is to say, the best coal, a ton of coal when packed in a ship leaves about 12½ cubic feet of interstitial space; that interstitial space is all that we require to be filled with carbonic acid gas, carbonic acid gas being antagonistic to combustion. Given, 1,000 tons of coal in a ship, we would then have 12,500 cubic feet of interstitial space to fill with gas, and to fill that interstitial space with carbonic acid gas would require 36 cwt. of chalk and 80 cwt. of hydrochloric acid, therefore, for 1,000 tons you may say the expense would be about 80 cwt. of hydrochloric acid, which costs, exclusive of carboys, about 2*l.* per ton, the chalk being merely nominal. The size of the cistern which would be required would be about 12 feet long, 6 feet wide, and 6 feet deep. Probably an objection might be raised to having to provide a cistern of that size, but it might be used in the passage out as a store for fresh water. If even the chalk was placed in it, the chalk would do the water no harm, but the chalk might be kept outside. The expense of the apparatus would be merely nominal. The temperature at which coal might ignite is an important question. I see Professor Graham in his report on the firing of the "Amazon," goes into that question, and he shows that coal may ignite at very low temperatures; but the conditions that Professor Graham refers to would not be present, such as laying the coal upon hot spaces. We don't expect that the coal would be laid upon hot spaces, except it might be in a steam ship.

1818. You have explained to us the precautions you would take in the case of actual combustion. Have you any recommendations to make to the Commission with regard to what should be done to prevent the spontaneous combustion of coal either in respect to the loading of the coal, or in any other respect?—I know of no means that would prevent the firing of the coal taking coal as it is ordinarily shipped on board ships. I think the firing of the coal is only a question of time.

1819. You mean there is no one method of loading better than another?—I know of no one mode of loading better than another. The coal is usually lowered down, and the interstitial space is a matter of accident. When I gave you 12½ cubic feet in a ton, I took that from an average of 27 different kinds of coal.

1820. You do not consider that the coal falling any distance, and breaking and becoming smaller adds to the danger of spontaneous combustion?—If we take the observations of Dr. Percy as regards small and finely-divided coal, of course if you increase the quantity of that finely-divided coal by a greater fall, you increase the danger from that source.

1821. Do I gather from what you have said, that you think the less amount of air which has access to the interior of the coal the better?—That is my meaning, taking other things into account.

1822. So that in the ordinary sense of the word the ventilation of north country coal is prejudicial?—Decidedly. I have come to that conclusion.

1823. Your recommendation, therefore, would be to do absolutely without internal ventilation, and to take that precaution which you have described to us in the event of heating?—Yes, that the captain should always have the means of knowing whether his coal was heating. Given the application of carbonic acid, if it was not applied till the coal was in active combustion it might be prejudicial rather than beneficial. If there was any mass of coal in active combustion it would decompose the carbonic acid and become carbonic oxide, and so tend to feed the fire.

1824. In all cases you say the spontaneous ignition of the coal is only a question of time. Are not some denominations of coal much more liable to combustion than others?—I cannot speak from absolute observation. I should say there would be. I know when I want coal brasses I go to different collieries to get them. I go to a particular colliery if I want a hard and massive coal brass, if I wish to burn it to get the sulphur out; and I know that in other collieries the bisulpide is so finely divided, and the coal is so finely divided, that it is of very little use for my purpose, and the coal of those collieries in which it is in that finely-divided state would be more likely to take fire.

1825. You consider that some coal is much more likely to take fire on board ships than others?—As a matter of opinion, I do not speak from experience. I have told you on what I base my opinion.

1826. You are not prepared to mention any facts tending to show the unfitness of certain classes of coal to be shipped long voyages?—No. I may mention that I have had put into my hand a great number of returns from the Board of Trade, on looking through which it appeared to me that it would be very useful if, on the captain applying to the consul for the usual protest in any case of loss or damage to the ship or cargo by the spontaneous combustion of coal, certain questions were put to him. The questions which I would suggest should be put to him are as follows: 1. Name of ship? 2. When, where, and of what build; also class, sailing, or steam? 3. Was vessel tight when loaded? 4. Was vessel tight when in a gale or straining? 5. How often did you pump bilge, and what quantity each time 6. Was bilge water warm, hot, or cold? Colliery coals came from; and was it round, unscreened, or small? 8. Was cargo put on board dry, damp, or wet? 9. Was cargo ever wetted from the deck or bilge? 10. Date when loaded and where? 11. Date when first satisfied cargo was on

Mr. J. Glover.

29 June 1875.

fire, and what latitude and longitude? 12. In what part of ship did fire commence? 13. Was cargo ventilated, and if so, state method employed? 14. Weight of cargo?

1827. (*Mr. Abel.*) In referring to the influence of pyrites in bringing about spontaneous heating of coal, you spoke mainly with reference to the state of division of the pyrites; do you consider that the state of division is the only reason why pyrites in some instances favours spontaneous heating of coal more than in others?—I do come to that conclusion most decidedly. I find that a mass of pyrites, free from admixture with coaly matter, is not liable to ignition; for instance, we bring large quantities of pure pyrites to this country without the admixture of coaly matter, but we never have such a thing as spontaneous combustion in them. I keep perhaps many hundreds of tons in our works for 12 months, and find no appearance of combustion, that is in pure bisulphide of iron, but I cannot keep coals for half or perhaps a fourth of that time without their igniting spontaneously; they may ignite spontaneously without any appearance of heating on the outside. I have found when I have got to the bottom of the gears, (which are the woodwork supporting the platform on which the waggons run bringing the coal to our works,) that the gears are burnt through.

1828. Are there some kinds of pyrites that are more liable to change than others, not speaking exclusively of pyrites which exists in coal?—I think some change more than others, but not in the direction of spontaneous combustion.

1829. In what way do you consider the hydrocarbons which you spoke of as having found in schistose coal contribute to the spontaneous heating of coal?—Granted a slight heating in the coal and an evolution of that highly volatile gas, I think it quite possible that that gas might ignite; some of these gases ignite at very low temperatures, much below that necessary to ignite coal. It is just possible that that gas might be given out by the gentle heat that is evolved from coal.

1830. You think it would ignite at a lower temperature than sulphur would ignite at?—Considerably. The flashing point as defined by the Act of Parliament of many of the hydro-carbon oils is from 120° to 150°.

1831. That is the temperature at which the vapour is given off but not the temperature at which the vapour ignites?—No.

1832. Whatever the temperature at which the vapour is given off all those hydro-carbons ignite at very high temperatures, do they not?—I am not aware of that.

1833. And sulphur at a comparatively low temperature?—About 230°. Its melting point is about 230, and it spontaneously ignites at 300 or thereabouts.

1834. You do not consider that the hydro-carbons in any way directly contribute to spontaneous heating, do you?—It is a theory I throw out mainly based on what I observe in Dr. Percy's table with regard to the non-inflammability of some coal bearing a relation to the schistose quality of the coal. And from having experimented on the schist of the coal measures and finding a quantity of light hydro-carbon vapour, given off, it struck me that there might be some connection between the two which this Commission might work out.

1835. Is not the schistose coal a more porous coal than the compact coal?—The schist is a very compact substance, like slate; it is called slate in our neighbourhood.

1836. You do not consider that it is more porous than compact coal, that is to say, than ordinary pit coal?—Not more porous, I should say, it was less porous. You can split it up into thin laminæ.

1837. Would not that indicate that it would be more permeable by gas or air?—The laminæ are perfectly invisible; with a sharp instrument you can strike the schist in such a manner that you can separate it into aminæ.

1838. As it separates into laminæ or very thin layers the structure must be comparatively speaking open?—Not so loose as coal; you can break coal into thin layers.

1839. You do not consider that this schist would be more liable to absorb oxygen or other gases than hard coal?—I could not answer the question without experiment.

1840. You consider that the state of division of the coal is of considerable importance as affecting the question of spontaneous combustion?—I do consider so.

1841. Have you any personal experience which you can give as a reason for considering that the state of division of the coal must exercise a considerable prejudicial influence?—I know that all carbonaceous matter when in a state of fine division is subject to spontaneous ignition, and coal would be no exception, and especially gas coal, but it must be in a large mass; you must have a considerable mass before you can have either from brasses or from finely-divided carbon such an evolution of heat as would lead to combustion.

1842. You have no special views or facts to give us with regard to the influence of a fine state of division of the coal?—No, my views are somewhat vague upon the question of the effect of that state of fine division of the coal.

1843. In speaking of applying carbonic acid for the purpose of extinguishing fire in a cargo of coal, you spoke of the inadvisability of applying it when the fire had reached some considerable dimensions or any dimensions at all?—Yes.

1844. Why would it be inadvisable to apply it under those circumstances?—When you have coal in active combustion, that is when the heat is high, that is a condition in which the carbonic acid may be decomposed.

1845. The fire must have reached to a considerable degree of intensity to produce that result?—Yes, but it might be localised, and then it would reach a state of considerable intensity. It would scarcely have reached that intensity without having manifested its presence even if there were none of those tubes which I recommend, but with the tubes I think it could not possibly have reached that state of intensity, therefore I would have the tubes as an essential part of the apparatus.

1846. You consider your method of applying carbonic acid would be applicable provided proper temperature observations were made?—Quite so.

1847. (*Dr. Percy.*) Have you any personal experience of the spontaneous ignition of coal in a mass?—As a manufacturer I have. I have had many such cases.

1848. Did you observe the conditions under which that ignition took place?—The condition that would be necessary to satisfy you I think was not observed; the only fact that I did observe was that when the coal was worked out and the men had taken it away in their barrows, I saw that the gears were burnt through. What was the condition of the coal in contact with the gears at the moment they were bared, I do not know.

1849. You had not an opportunity of inspecting the phenomena that occurred in those cases?—No.

1850. Your conclusions are based upon chemical knowledge, and not on individual personal experience?—Based on my chemical knowledge, but in our chemical works we do sometimes use large quantities of brasses; we have them laid down in a mass, and we know from experience that we cannot have them lying there a month without great risk of the whole mass firing. We have to use them up as fast as we get them.

1851. You are speaking of pyrites from coal measures?—Yes.

1852. If I understand you correctly there are no precautions requisite to be taken with regard to the other kind of pyrites?—Not the slightest. After 30 years' experience with pure pyrites from all parts of the world I may say that I never knew a case of spontaneous ignition in any of the pyrites properly so called.

1853. You have not known any case of spontaneous

Mr. J. Glover.

29 June 1875.

ignition of pyrites unless intermingled with carbonaceous matter ?—Not unless intermingled with carbonaceous matter.

1854. In your opinion that is the condition of this ignition ?—That is the condition of spontaneous ignition. With bi-sulphide of iron alone, so far as my experience goes, there is no danger, but where you have bi-sulphide in combination with carbonaceous matter, then there is danger.

1855. With regard to this schist, the schist weathers pretty rapidly when exposed, does it not ?—Some of the schists do.

1856. Do not most of them, those, for instance, that are raised out of the collieries, and which you see in mounds at the top of the pit's mouth, do not those weather and split up rapidly when exposed ?—I have often gone round a colliery mound to examine the heaps, and I have not observed that they are weathered in all cases.

1857. Have not you seen some rapidly fall to pieces ?—Yes. I have seen some rapidly fall to pieces.

1858. Have you made any experiments with regard to the quantity of pyrites in those schists ?—No, I have not.

1859. You do not know whether it would be present in any sensible amount ?—No.

1860. The schist to which you refer contains coaly matter ?—Yes.

1861. Have you seen heaps of this schist on fire ?—Yes, I have frequently seen them on fire; it burns from quite black to white, which is a proof that it is coaly matter, I think, and not bisulphate of iron.

1862. As to gas coal, in your term "gas coal" would you include good cannel coal ?—Yes.

1863. Do you think that that is likely to ignite spontaneously ?—I think finely-divided portions of cannel coal would be very likely to ignite spontaneously.

1864. Is that simply a chemical opinion you have formed, or is it the result of personal experience ?—Entirely a chemical opinion. We do not use cannel coal in the north to any extent.

1865. With regard to your proposal to use hydrochloric acid to generate carbonic acid, how would you recommend that acid to be kept on board ship safely ?—I know of no other method but the ordinary method of keeping it in carboys.

1866. If they were to break it would be rather awkward, would it not ?—Yes, but it is not a very corrosive acid.

1867. Still it would be unpleasant ?—Yes.

1868. With regard to spontaneous ignition of finely-divided coal have you any personal experience upon that subject ?—No, I have not. How far the tendency to spontaneous ignition is due to the finely-divided state of the coal, or how far it is due to the presence of brasses, I have no means of knowing.

1869. (*Mr. Ferguson.*) Do you consider that coals shipped wet are more liable to spontaneous ignition than coals shipped dry ?—Decidedly; moisture is one of the main conditions tending to the firing of coal.

1870. If coal were shipped dry there would be less danger of ignition ?—If coal were shipped dry there would be less danger of ignition. That reminds me of a suggestion I was going to make, that perhaps it might be possible in case of coal being shipped wet to inject through the coal a current of hot air by the tubes I have mentioned. It would not cost much to do that.

1871. If coal were shipped dry there would be less danger, you think ?—If shipped dry and kept dry there would be very little danger, and therefore I would suggest that it is very important that the surface of the coal be ventilated, and the shafts for ventilation should be carried well up he mast, so that in shipping a sea it should not go into the coal.

1872. There is a danger in ordinary ventilators of water getting down the ventilators ?—Yes.

1873. You do not approve of the ventilators being carried through the coals ?—Not through the coals, but it is imperative that the surface should be ventilated, there should be a wooden trunk carried up the mast, so high that in shipping a sea there would be no danger of its going into the cargo.

1874. (*Mr. Duncan.*) You have stated that you think the coals being shipped wet is a great predisposing cause of their taking fire spontaneously, what inference would you draw from this fact, that it appears from the ascertained statistics that the cargoes of the greater part of the large number of ships that sailed in 1873 and 1874 were shipped in the driest months of the year ?—I am not prepared to draw any inference at all from that fact. I would first require to know all the particulars in such cases; though the cargoes were shipped in the driest months of the year, it does not follow that they were shipped dry. I would require to know whether there were thunderstorms at the time, and whether the bilge water was allowed to come in contact with the lower part of the coal, and whether the ship in straining made water. All those facts would have to be ascertained before I could give an answer.

1875. Are you so confirmed in your opinion that water is the cause of spontaneous combustion that you would still hold to that opinion, notwithstanding such cases were brought to your notice as we have had brought before us in evidence to-day, by Mr. Steinson, who told us that three cargoes were shipped in perfectly dry weather, and that the ships were well ventilated, notwithstanding which the ships were burnt, whereas in a fourth case, where the cargo was shipped very wet, and where the ship was not ventilated, it went perfectly safe ?—As I said before, if any inference is to be drawn from the dryness of the coal, or as to the effect of moisture in producing spontaneous combustion, you require to know all the facts; for instance, you would require to know not only whether the three cargoes were shipped dry, but whether they were kept dry.

1876. If you had a pile of coals on your own premises you would roof them over, I presume, in order to keep them dry ?—Yes; the drier coals are kept the less they will deteriorate, and they will not be so liable to take fire, whereas if coals were not covered, they would take fire.

1877. (*Mr. Vivian.*) Do you think that the coal that is wrought and shipped now in the north of England contains more shale than it used to do ?—I cannot say whether it does or not.

1878. Not being interested in shipping coal, you have had no means of observing ?—No.

1879. Do you find that it is more dirty than it used to be ?—I find the small coal decidedly dirtier than it used to be.

1880. What per-centage of ash does your small coal contain ?—The per-centage of ash varies; from the best quality of coal we got 8 to 10 per cent. and I have found in some descriptions as much as 22 and 23 per cent. of ash.

1881. Are you able to state what it used to be in former days ?—In former days, (unless we went to a particular coal, which I need not specify,) the average amount of ash, so far as my recollection goes, would be about 10 or 12 per cent.

1882. 10 or 12 per cent. against what ?—At present from the best that we get it is about 10 per cent. In a great deal that we get from the steam coal field it is about from 18 to 22, and I have known it 23, but that is only in some steam coals. I observed that large per-centage in a description of coal from some collieries which I had not previously gone to, so that it does not follow that the per-centage would be larger in that kind of coal, because I had not an opportunity previously of trying that kind of coal. These per-centages are the result of experiment; we try every cargo of coal that comes into the works for ash.

1883. So that the small of the steam coal in your district contains a large amount of ash as now delivered ?—It contains a large amount of ash as now delivered; what might have been the amount previously I have no means of stating authoritatively.

1884. If as we have heard, shale is spontaneously ignitable, that may to some extent account for the

Mr. J. Glover.

29 June 1875.

increase in the number of cases of spontaneous ignition which have occurred during the past few years?—If a certain amount of shale is present in the coal, and if it is spontaneously ignitable, as I believe it is, the amount of shale would render the cargo more liable to spontaneous ignition, but I may mention that most of the shale comes into the small coal, in fact I should think nearly all the shale comes into the small coal.

1885. In your judgment would coal which contains no sulphur ignite?—It would not ignite from the cause that leads to the fixation of oxygen by sulphur and iron combined with sulphur; but taking Dr. Percy's view of the matter, if it contained very finely-divided smal coal, it would be as liable to ignition if it contained no sulphide, owing to the finely-divided state of the small coal

1886. You said in the early part of your evidence that in order to ignite under those conditions a certain quantity of coal must be heaped together?—Yes.

1887. Can you state what quantity that should be?—I would be a rather bold man to state the quantity, but certainly it would be a very large heap, not less I should say than from 200 to 500 tons.

1888. The depth would have to do with the spontaneous ignitability of such coal?—Yes, certainly.

1889. What would you put as the depth of a heap in which you would say spontaneous combustion would be likely to take place?—If you had a depth of 8 feet to 12 feet, you would have a condition in which the coal would spontaneously ignite. I have certainly seen ordinary small spontaneously ignite under a depth of 15 feet repeatedly.

1890. That was coal that contained pyrites?—Yes, and shales.

1891. I am speaking of coal which contains no pyrites?—I have no experimental proof in that direction; it is all matter of opinion.

1892. You said that coal brasses would ignite, what per-centage of sulphur would those coal brasses contain?—They vary a great deal, they contain from 22 up to 30 per cent. of sulphur.

1893. And the ordinary Spanish pyrites contains what?—From 40 to 50 per cent.

1894. So that the difference between the two is probably made up of carbonaceous matter?—It is made of chiefly carbonaceous matter; almost entirely; you may say entirely carbonaceous matter.

1895. Have you ever received cargoes of small pyrites?—Frequently.

1896. Have you ever known them to heat?—Never we have kept small pyrites in the works for 11 years.

1897. Do you know of any sulphur existing in coal which is not in combination with iron?—I do not know of any, certainly.

1898. If sulphur were found by analysis in coal, you would naturally conclude that it existed in a state of pyrites?—Yes.

1899. Can you imagine any other combination in coal in which sulphur might exist?—I do not know of any, unless it is sulphate of lime.

1900. Sulphate of lime would be wholly undecomposable?—It is quite inert.

1901. What would be the cost of the apparatus you have suggested to the Commission?—I have not gone into the question of the cost, but the whole apparatus would not cost 20*l.*, perhaps 25*l.* would fit up the whole apparatus on board a large ship.

1902. Where would you place the apparatus?—In the most convenient part of the ship; of course in a coal-laden ship the apparatus should be placed on deck.

1903. How would you apply it?—The *modus operandi* would be simply when the thermometeric indication showed an increasing temperature, increasing up to a point which ought to be specified to the captain in charge of the ship.

1904. Interrupting you for a moment, what would that point be?—If I had charge of a ship, and observed the heating going on from the ordinary temperature till it had risen to about 200°, I should then give a dose of carbonic acid, observing still the thermometeric conditions, that dose would be given by pouring in the hydrochloric acid gently down the orifice, so that there should not be too much effervescence; the carbonic acid would find its way to the bottom of the ship, and you could fill the ship full with it, in the same way as you could with water.

1905. Would you connect the pipe leading from the apparatus with the hose?—I would have iron gas pipes laid down into as many compartments as the ship may be divided into, and connect them with a pipe issuing from this apparatus, probably by a coupling or connection of indian rubber pipe; indian rubber pipe would probably be the best, because it would give with the motion of the ship. On pouring in the hydrochloric acid, the gas would be evolved, and it being a very dense gas, it would find its way to the bottom of the ship, filling all the interstices; of course, no human being must be below at the time.

1906. You would pass it down the pipe which showed heat?—No, those pipes would simply act as indicators; but, certainly, if those pipes were perforated at the bottom, you might put it down the pipes themselves.

1907. You would continue to pour in the carbonic acid till the whole of the interstices of the coal were filled up with carbonic acid?—Till the whole of the interstices were filled. As I mentioned, a thousand ton ship would require about 36 cwt. of carbonate of lime or ordinary chalk, and about 80 cwt. of acid of the common strength of the chemical works. You would get it at 2*l.* a ton, then there would be the cost of the carboys, which would be more than the acid, where the contents of the carboy might cost 2*s.*, the carboy itself would cost 3*s.* or 4*s.*

1908. You believe that carbonic acid existing in the condition of dry gas, would be sufficient to arrest the decomposition of the pyrites?—I think it would entirely. I think it would prevent the decomposition of the pyrites, and therefore the evolution of heat. I do not think pyrites would decompose even with moisture in the presence of carbonic acid.

1909. You consider the presence of carbonic acid would arrest the decomposition of the pyrites?—Both arrest decomposition and put out any fire present, provided the fire had not got into a state of violent incandescence.

1910. Fire would hardly exist at the temperature you have given, 200°?—The heating might inadvertently rise to 400° or 500°.

1911. If you poured it on when there was a temperature of 200°, it would be when the decomposition of the pyrites was going on?—Yes.

1912. Would the presence of carbonic acid arrest that decomposition?—I think it would. Experiments would have to be made; it is a thing to ascertain by experiment with a large quantity of coal, whether the decomposition might not go on further, because many a ship has got to its journey's end safely, which if the voyage had been continued a little longer, so that the process of decomposition had gone on a little further, might have been burnt.

1913. Carbonic acid being a very heavy gas, would, I presume, expel the air from the interstices and take its place and remain there permanently?—Yes, unless it was highly heated.

1914. Would there be any danger to the men in discharging that ship?—The ship would have to be carefully attended to if the dosing with carbonic acid had been just before the ship making its port. The presence of carbonic acid could be easily determined by lowering down a light which would be put out at once.

1915. It is conceivable that the carbonic acid might remain occupying the whole of the interstices of the ship till she reached the end of her voyage?—If the ship was heated up to 250°, so that when the carbonic acid got heated up to that heat, it would be apt to be displaced by the surrounding air, it would simply arrest it for a time, but that time might save the ship. If a portion of the coal had really got into a state of slow combustion it would arrest that combustion; but

Mr. J. Glover.

29 June 1875.

as to saying that when once filled with gas it would remain there the whole voyage, I think it would not.

1916. You would not recommend giving the ship a dose of carbonic acid before she started as part of her cargo?—No, I would recommend, if possible, drying the cargo by giving it a dose of warm air. When you give a dose of carbonic acid, you must have no living being below deck.

1917. (*Mr. Duncan.*) That is a practical question that has been occurring to me, because in many ships the crew live forward below the deck, they would have to live on deck during the administration of this carbonic acid?—They would have to choose the least of the two evils and live on deck.

1918. (*Mr. Vivian.*) Or you might have tight bulk heads to keep the gas away from that portion of the ship?—Yes.

1919. (*Mr. Abel.*) With regard to your proposed application of carbonic acid, I believe, however dense a gas is, it has a tendency to diffuse itself into the air, has it not?—Yes.

1920. So, that unless your hold were perfectly gas-tight, the carbonic acid would gradually diffuse itself into the air in other portions of the ship?—Into all the other portions of the ship; but supposing your bulkheads were perfectly tight it could not diffuse itself through an iron bulkhead.

1921. It would be necessary to have gas-tight bulkheads in order to imprison the carbonic acid?—In one particular place.

1922. In order to prevent its finding its way to other portions of the ship?—Suppose you had a ship divided into three bulkheads, you would have three separate pipes proceeding to your carbonic acid apparatus. Suppose the middle compartment was heating, you would connect the middle compartment with the carbonic acid apparatus.

1923. With reference to the sulphur existing in the coal, if you found the proportion of sulphur in a coal to be considerably in excess of that required to combine with the iron which you found, you would come to the conclusion that there must be some sulphur not in combination with iron?—Yes.

1924. Have you not known that to occur in many instances?—No.

1925. Have you not seen some analyses published by Dr. Percy of coals, in which the amount of the sulphur is very much in excess of that required to combine with the iron in order to form pyrites?—I have not read that in Dr. Percy's work.

1926. Have you ever heard of a schistose mineral containing no iron at all, but containing a considerable quantity of sulphur in its composition?—No.

1927. (*Chairman.*) You said you would require as much as 80 cwt. of muriatic acid to produce enough carbonic acid to permeate the whole mass of a thousand tons, how much does a carboy hold?—A carboy holds about 1 cwt.

1928. So that you would require to carry 80 carboys on deck. You could not put the carboys below?—The carboys could be carried easily on the surface of the coal.

1929. If I am not mistaken acid is obliged to be carried on deck in an ordinary merchant ship?—Yes.

1930. You would make a special exemption in a coal carrying ship, and allow a certain quantity of acid to be stowed below?—Yes; there is no other apparatus that would carry it, unless you fitted up a wooden cistern to hold the muriatic acid, and then it would be difficult to keep it tight, perhaps you could make it perfectly tight by gutta percha.

1931. Otherwise 80 cwt. of muriatic acid on deck would be rather an awkward load, would not it?—Yes.

1932. (*Dr. Percy.*) You would have a wooden case tarred?—Yes, it would last the voyage, probably. My experience of gutta percha is so adverse that I do not recommend it; a stone cistern would hold it; a wooden case tarred would hold it a long time, but the slightest permeation of the acid through the pores of the wood coming in contact with the bolts that bound the cistern together, would eat them away in time. I know that in storing muriatic acid we never use wooden cisterns, we always use stone cisterns.

1933. Have you ever made any experiment with regard to the effect of steam in extinguishing fire?—Never, but I should think it would not put out a fire.

1934. Supposing we had steam at our command, and we blew that steam down on a mass of coal in ignition, what do you think would be the effect?—Whether it would put the fire out or not I would be inclined to doubt along with Professor Graham in his report. Professor Graham seems to think that it would be of little use; the objection I would have to the use of steam would be the quantity you would have to blow in, and the consequent condensation of that quantity, wetting the coal again.

1935. You say you have made a determination of the per-centage of ash in the coal, did you ever make a determination of the quantity of water contained in the coal supplied to you?—Yes; we find taking 19 cargoes out of 20 we got about three per cent. of moisture in the coal.

1936. Quite sufficient moisture, supposing the air gets access to the coal to ignite the pyrites?—I think so; if that three per cent. remained in the coal as water, it would have that effect.

The witness withdrew.

Mr. EDMUND SQUIRE ROBERTS examined.

Mr. E. S. Roberts.

1937. (*Chairman.*) You are inspector for the Peninsular and Oriental Company in respect of their coal shipments at Cardiff?—Yes.

1938. How many years have you been in their employ?—Seven years.

1939. Can you give the Commission any idea of the number of the ships, and the tonnage of the cargoes that you have inspected?—We ship about 150,000 tons during the 12 months, and I should think nearly 100 vessels are employed. I did not look at my books, but I think about 100 vessels load during the year.

1940. I may take it roughly that you have inspected 1,000,000 tons of coal and some 700 ships?—Yes.

1941. Have you had more or less during the last few years?—More. I ought to say perhaps in the first year we did not have so much as the quantity I have mentioned. It is lately that we have had more.

1942. Have you had any cases of spontaneous combustion or explosion of coal shipped from South Wales?—I have had only one case of explosion.

1943. And none of spontaneous combustion?—None of spontaneous combustion.

1944. What do you attribute that remarkable immunity to?—That we ship the best steam coal in the district.

1945. And that the best steam coal is not subject to spontaneous combustion?—I think that the best steam coal is not subject to spontaneous combustion.

1946. With regard to ventilation, does the Peninsular and Oriental Company lay down any rules as to ventilation?—No rules whatever.

1947. What do you find as a matter of practice is generally done as regards ventilation?—We find as a rule, they wish to construct large wooden ventilators throughout the ship.

1948. And they do so?—Yes.

1949. You do not charter the ships?—No.

1950. You only contract with the charterers?—Yes.

1951. Therefore you do not interfere?—Not in the least.

1952. What is your opinion with regard to the question of ventilation?—That it is better left alone altogether than done in the way it is generally done.

1953. That is that air should not be allowed to permeate through the coal?—Yes.

1954. All that you require in your judgment is to

Mr. *E. S. Roberts.*

29 June 1875.

keep the gases from the surface?—I think you require ventilation on the top. I look out for something of that sort. I have no orders to do so; but I impress upon the captains to have the hatches a little free, and to have ventilators at either end of the vessel.

1955. That is in order to carry off the gas and keep a current of cool air on the surface?—Yes.

1956. Beyond that you would not go?—No, I think it prejudicial to the safety of the coal to do anything else.

1957. Why do you think it prejudicial?—I think by having those ventilators in the bottom of the ship and having them up and down the hatchways, you create a draught and you raise the enemy you are trying to keep out.

1958. If the coal gets heated and a draught passes through it, it is more likely to increase the combustion?—I think so.

1959. At any rate from what experience you have had, you think the risk is less in keeping air from the interior of the coal altogether?—Yes, I do; all the ships I have heard of, where they have had, what they call spontaneous combustion, which I do not believe in, have been ventilated.

1960. You say that you do not believe in spontaneous combustion. You have no doubt heard of ships with which you have had nothing to do, in which fires have taken place?—Yes, which have been said to have been caused from spontaneous combustion; but I think, it has been from carelessness. It has no doubt been from explosive gases.

1961. Are you speaking of South Wales coal?—Yes.

1962. You are aware that with regard to the north country coal, there is no question that the coal does take fire?—I understand so; I do not know much about north country coal.

1963. Speaking of South Wales coal, you know of no case well substantiated, of actual spontaneous combustion?—I do not.

1964. Though you do know of cases of explosion?—Yes.

1965. Where gas has collected which has been accidentally lighted?—Yes; by people taking a light, or by some means or other.

1966. Not gas which in itself would be liable to take fire by contact with oxygen?—No, not at all.

1967. Can you tell us anything about your method of shipping coal? does the Peninsular and Oriental Company insist upon shippers shipping in any particular way?—Yes; we are very particular, we make them lower the coal into each hatchway till there is a sufficient quantity raised in each hatchway, so that it should not break.

1968. So that there should never be a heavy fall?—No great fall.

1969. Will you explain the method?—We have a box which we put at the end of the shoot, which box, after it is filled, is lowered down to the bottom of the ship till we get a good pile of coal, then the remainder of the coal is allowed to run on to this pile of coal which has been formed by the box.

1970. You say the box is put at the end of the shoot?—Yes; the coal goes down the shoot; there is an iron tub or box which comes to the mouth of the shoot and is filled; when that box is filled they stop the run of coal in the shoot and then they lower the box down.

1971. And then they raise the same box up again?—They raise the box up; it is a system that requires a great deal of attention.

1972. It also takes a great deal of time?—Yes.

1973. How many tons can be put into the ship in an hour upon that plan?—I am not prepared to answer that.

1974. Can you tell how long it takes to fill up the hatchway?—That would be according to the depth of the hatchway. I should say 10 waggons could be carefully shipped in an hour; but it would be expensive, and would take a long time comparatively, because the same quantity of coal could be tipped in 15 minutes.

1975. Your preference for this method is on account of the avoidance of breakage?—Yes.

1976. You have not in view the consequent risk of combustion?—No; only I consider that it is the small coal that is likely to generate gas.

1977. All that you look to is to see that you get the coal you contract for?—To see that we get large lumps rather than small.

1978. Your instructions from the company do not point to the danger of combustion?—They do not allude to it in any way.

1979. The danger has not been thought of?—It has not been thought of in South Wales at all.

1980. Have you had any experience in respect of the storage of coal in large quantities?—I have.

1981. Where?—In Alexandria.

1982. Where you agent for the company there?—No; I was in charge of a coal depôt. I was their marine superintendent, and I looked after all the cargoes shipped, and I looked after the supplying of the ships with coal. The agent was a gentleman on the shore who looked after the freights.

1983. You transacted their coal business?—Yes, for 12 months.

1984. While you were acting in that capacity had you any large amount of coal stored at any time?—A great quantity.

1985. Did you have any experience of combustion in the case of any of that coal?—Not with our own coal; but during the time I was there I saw other coal ignite belonging to other people, notably the Russian Government. They had a store close to us which ignited.

1986. (*Dr. Percy.*) What coal was it?—I am unable to say.

1987. (*Chairman.*) What was your coal?—Both kinds, north country and South Wales.

1988. Did you mix them?—No; we keep them in separate heaps.

1989. Did you apply any system of ventilation?—Yes, in each stack of coal as we landed it we always ran a tunnel through the coal fore and aft and athwart, and we had a sort of chimney built of the coal in the middle of the stack; that would be in a heap of 1,000 tons, for instance.

1990. What was the object of that ventilation?—To prevent spontaneous combustion.

1991. Did you apply that to both kinds of coal, both bituminous and South Wales?—Yes. The Arabs always understood they had to build this tunnel; that was a part of their contract.

1992. Did you consider that that ventilation was any good?—Yes.

1993. Why should it be of use on shore and not on board ship?—It is perfect on shore. There is air all round, as it were; the mass of coal is not confined in any way. There is a tunnel running in the coal one way, and across it in the other, and you have the air all round it, whereas in a ship you have not got the same conditions; it is confined on all sides.

1994. You do not think ventilation in itself mischievous, but it is mischievous because you cannot make it perfect?—Exactly.

1995. Were your stores covered at any time?—Yes, they were all covered, so that the coal was not exposed to wet.

1996. You had very little rain at Alexandria?—Except at certain seasons in January and December we have a great deal of rain, but all our coal was under cover. I should not like to leave it exposed to the rain.

1997. Was the reason you kept it covered to preserve it from deterioration, or because you thought if you did not keep it covered it would be liable to spontaneous combustion?—To preserve it from deterioration.

1998. You did not think there was any risk of its taking fire from its being uncovered?—No; we considered that the coal being exposed to the atmosphere, and the rain and the sun would disintegrate it, and thereby deteriorate it.

Mr. E. S. Roberts.

29 June 1875.

1999. You would not ventilate the interior of the coal on board ship; you would keep a current of air on the surface, and you would let the coal fall when it was being loaded as little as you could help?—Certainly.

2000. Have you any other suggestion to make to the Commission whose object is to see what should be done with reference to spontaneous combustion?—The only suggestion I could make is, that only the best coals should be sent on long voyages, and not those inferior coals.

2001. When you say "those inferior coals," the Peninsular and Oriental Company buy the best, I presume?—They try to do so.

2002. Have they occasionally found themselves buying inferior coal?—They find themselves with inferior coal, though not buying it.

2003. You mean the coal owner does not give them what they expect to get?—It does not always turn out so.

2004. Do they make their contracts at first hand with the coal owners?—Direct with the coal owners; but what I was more particularly referring to, was that there are certain coals from South Wales that it would be dangerous to carry on long voyages.

2005. Why are those coals dangerous?—Because they contain a great deal of iron pyrites.

2006. In your seven years' experience have you known of any casualties happening in ships carrying that description of coal?—I have heard of them, but I have not taken any particular notice of them.

2007. You know generally the kinds of coal that are to be avoided?—Yes.

2008. It is your duty to keep your principals well informed upon that point?—Yes, that is my principal duty down there to see that they do not get that sort of coal.

2009. The liability to spontaneous combustion is a matter you specially direct your attention to?—Yes, individually. I have no instructions to do so. I should warn my principals if I knew that coal was being shipped which I thought would be dangerous, but I have no instructions to do so.

2010. What classes of coal do you think ought not to be shipped for long voyages?—All those that have much iron pyrites in them, and also the coals in which there is a large intermixture of sulphur. No. 2 Rhondda from my district is a very dangerous coal.

2011. Is that an extensive seam?—Yes, it is very largely worked by nearly every colliery in the Rhondda Valley.

2012. Is there any other that you could put in the same category?—Some of the Monmouthshire coals I think are very dangerous.

2013. Could you give any general name that would describe them?—All the coal raised in Monmouthshire, which is not called the Elled vein.

2014. All other Monmouthshire coal you think liable to combustion?—Yes.

2015. (*Mr. Vivian.*) Would you say that all the Monmouthshire coals except the Elled vein are liable to spontaneous combustion?—They are more liable to spontaneous combustion than the Elled vein. I should say that all coal from the ironworks collieries of Monmouthshire and Glanmorganshire is very liable to combustion. We have a great deal of iron pyrites in the coal raised from those collieries, and I consider that a very dangerous coal.

2016. Are you acquainted with the Dowlais coal?—Yes, I have shipped a good deal of it.

2017. That is a first-class steam coal, is it not?—It is a very good steam coal.

2018. That is an ironworks coal, is it not?—Yes.

2019. Would not you except that?—No. I should say that was very liable to combustion.

2020. Dowlais coal is considered at least as good as any steam coal shipped in South Wales, is it not?—It is a beautiful coal.

2021. It is the highest class steam coal, is it not?—It is as good as the others.

2022. Do you consider that liable to spontaneous combustion?—They cannot keep the iron pyrites out of it. I have to see that they do not give us too much of it.

2023. Is not it worked from precisely the same beds as the regular steam coals of South Wales?—Yes, but it has this pyrites in it which is very difficult to entirely eradicate, and there being a great deal of that amongst the coal, it makes it a dangerous coal; there is more pyrites in the Dowlais coal than any coal I have to ship.

2024. Have you ever known any instance of Dowlais steam coal igniting spontaneausly?—Never one.

2025. The Cyfarthfa, Messrs. Crawshaw's, is a first class steam coal, is it not?—Yes.

2026. Have you ever known a case of that firing?—I think I have. I have heard of several cases, I think. I have not a very good opinion of that coal.

2027. Fothergills, Aberdare, is a coal which is very largely shipped, is it not?—Yes, that is a very dangerous coal.

2028. Have you ever heard of an instance of that catching fire?—No, it is full of iron pyrites.

2029. You have never known an instance of its catching fire?—No, I have never heard of one. We have never shipped much of it.

2030. That coal is as largely shipped as any coal in South Wales, is it not?—Yes, the only cargo of that that I had to do with I had to reject in consequence of its being very dirty and unfit for steam purposes. It is full of iron pyrites.

2031. Still you have never known any case of its catching fire?—No, but I do not look after cases of casualties that occur in any other coal but my own coal.

2031*a*. It is a matter of great importance to you to keep yourself well informed as to what coals do catch fire, is it not?—No, I cannot say that it is. It is not a matter my employers want to be posted up in at all. Till I had the honour of receiving a communication from you the matter has hardly been under my consideration at all.

2032. What coals have you chiefly shipped?—The best Aberdare and Merthyr coals, Davis's Merthyr and Ferndale, and we used to ship the best of the Powell Duffryn and Insoll's Merthyr.

2033. Nixon's?—No, I have shipped some of Nixon's, but not for my employers.

2034. Have you had no experience of spontaneous combustion in shipping any of the other coals you have mentioned?—I have had Fothergill's Aberdare under my notice and several of the Dowlais coals, which I consider very valuable coal, but very dangerous coal, so far as spontaneous combustion goes, if there is such a thing as spontaneous combustion. I should think it would generate gas very quickly.

2035. That would be inflammable gas, would it not?—Yes.

2036. That is to say, it would be liable to gas explosion, but not spontaneous combustion?—Just so. My private opinion is that most of the cases that are reported as cases of spontaneous combustion are merely from ignition.

2037. Are you aware that most of those cases occur after a lengthened voyage?—No, I have not heard that.

2038. The evidence received by the Commission is that the cases of fire occur pretty generally towards the end of the voyage after the ships have been at sea a long time?—I have not heard that.

2039. By that time the volatile gases would have passed off to a great extent, would they not?—No, I think not. Probably they have kept the hatchways bunged up, and there has not been any proper ventilation, and then some fellow has gone down with a light and made the coal ignite, but, of course, they would not acknowledge that; they would rather have it spontaneous combustion.

2040. Have you shipped patent fuel?—I have shipped some fuel at Swansea, several cargoes of it.

2041. Have you ever heard of patent fuel catching fire?—I have not.

2042. (*Mr. Fenwick.*) Is the coal which is shipped at Cardiff for the Peninsular and Oriental chiefly for short voyages for the Mediterranean?—A great deal of it is shipped for India, quite half of it goes to India.

2043. Is that shipped in sailing vessels or steam vessels?—Principally in sailing vessels. We ship to

Mr. E. S. Roberts.

29 June 1875.

Bombay in steamers. Formerly we used to ship by sailing vessels.

2044. In what kind of ship is the coal for the Mediterranean carried ?—Mostly in steamers.

2045. You do not advocate ventilation ?—No, not internal ventilation, but surface ventilation.

2046. (*Mr. Icely.*) Will you inform the Commission what your instructions are with regard to the shipment of coal for the Peninsular and Oriental Company ?—To see that we get coal instead of stones; that is all.

2047. Nothing beyond ?—To see that the coal is carefully shipped ?—The principal thing is to see that we get good coal according to contract.

2048. Have you any directions as to screening the coal ?—We do not screen our coal now; we formerly used to screen it.

2049. Is not it even single screened ?—It is screened at the pit's mouth; that is all.

2050. You have had no cases of spontaneous combustion in the coal you have shipped for the Peninsular and Oriental ?—None whatever. I have only had one case of ignition. In that case the ship was loaded with ocean coal at Penarth. That casualty occurred about two days before she left the dock.

2051. If there had been any such cases, would they have come to your knowledge ?—Yes. Of course inquiries would have been made as to the condition of the coal when shipped.

2052. When once the coal is shipped if any accident happens to the cargo, have the Peninsular and Oriental Company to suffer the loss ?—They insure the cargo.

2053. Do you attribute this immunity from danger in the case of the Peninsular and Oriental shipments, compared to those of other people, to the careful inspection given by you as the representative of the Peninsular and Oriental Company ?—No, I cannot say that.

2054. You do not think it is owing to their careful inspection that the immunity from danger has arisen ?—I am rather diffident in answering your question, for I might be supposed to be lauding my own carefulness, but we see that the coal is in good order before it is shipped.

2055. There is no screening, I understand you to say ?—Not lately. We ship it colliery screened.

2056. It is screened at the colliery, but not on shipment ?—No, except on certain occasions. If I see the coal has got too much small in it, they screen it again upon my suggestion, but we do not pay for it screened; we pay for it colliery screened.

2057. (*Mr. Abel.*) You referred to one case of explosion on board a coal-laden ship; could you give us any details with regard to that ?—[*]

2058. That is the only instance of explosion which has come under your personal knowledge ?—Yes.

2059. Yet you consider explosion is the main danger to be guarded against in the shipping of coal ?—Yes.

2060. You do not believe there is any great liability to spontaneous heating of coal ?—Not in the coal I am speaking of.

2061. (*Dr. Percy.*) I think you said that you reject coal containing iron pyrites in any sensible amount ?—Yes, I frequently do.

2062. Simply because the coal containing it would be of inferior value, not as I understand you, because you feared that spontaneous combustion might arise from it ?—No, merely because I considered it inferior coal, having regard to the inferior qualities required of it as steam coal; not with regard to liability to spontaneous combustion.

2063. Is not it conceivable in the case of coal inspection that there may be such a thing as a very strong temptation offered to the inspector to pass coal of inferior value ?—Quite conceivable.

2064. Where a man was not proof against temptation ?—Quite possible, probable, and very likely exists.

2065. (*Mr. Duncan.*) Quite irrespective of inspection at all, there is a large quantity of coal shipped that is in your judgment unfit to be sent on long voyages ?—A great deal.

2066. People buy a cargo of coal and take the chance of it ?—They take the chance of losing the ship and everything else.

2067. (*Chairman.*) It is your view that a coal may be an admirable steam coal and very good for shipment for a short distance that ought not to be shipped for voyages of three and four months ?—Exactly so; and no people having any knowledge of that coal would sent it on a long voyage.

2068. Do you know anything about the rate of insurance upon coal now ?—No.

2069. You said that the Peninsular and Oriental insured their coal. Do you mean they insure it in their assurance fund ?—They insure it at Lloyd's or in other offices. I think it is rather a considerable item with them.

2070. Their insurance fund only covers their own ships ?—Yes, their cargoes are insured in outside offices.

2071. (*Mr. Duncan.*) Do you think, owing to the pressure there was during the last two years 1873 and 1874 to get coals, people were tempted to send away a class of coal that would not have been sent away at other times ?—I think so, certainly. They would ship anything black.

2072. (*Mr. Vivian.*) You have stated generally that you consider ironworks' coal to be liable to spontaneous combustion and dangerous. Could you when you return home refer to the shipments of ironworks' coal and furnish the Commission with any data upon which your opinion is based ?—No, I could not. It is only my personal conviction.

2073. It is an opinion based upon no facts whatever ?—It is only my opinion.

The witness withdrew.

Adjourned to Tuesday next at 12 o'clock.

Tuesday, 6th July 1875.

PRESENT :

THE RIGHT HON. HUGH C. E. CHILDERS, M.P., IN THE CHAIR.

SIR GEORGE ELLIOT, Bart., M.P.
HENRY HUSSEY VIVIAN, Esq., M.P.
FREDERICK AUGUSTUS ABEL, Esq., F.R.S.
RICHARD CORY, Esq.
GEORGE DUNCAN, Esq.
JOHN FENWICK, Esq.
CHARLES ICELY, Esq.
JOHN PERCY, Esq., M.D., F.R.S.
WILLIAM YOUNG, Esq.

J. M. CARMICHAEL, Esq., Secretary.

MR. EDWARD BENJAMIN SCOTT examined.

Mr. E. B. Scott.

6 July 1875.

2074. (*Chairman.*) You are a partner in the firm of Messrs. Gillespy and Scott ?—I am.

2075. You have had great experience in the shipment of coal ?—Yes, for a considerable number of years.

2076. Your firm has been established some years ?—Since 1857.

2077. You have shipped largely for Her Majesty's service ?—Yes, and our predecessor also, Mr. Thomas Gillespy.

---

[*] Mr. Roberts thought he would be able to furnish these details on his return to Cardiff, but he subsequently wrote :—"I regret being unable to give any particulars of the reported case of explosion in a coal-laden vessel as referred to in my evidence before the Royal Commission on Spontaneous Combustion in Coal (in No. 2057), as I find that upon the investigation held on this case, it was considered doubtful whether it was an explosion of gas or ignited by a fire (that the coal itself was ignited by a fire arising from the vessel's stores having first ignited").

Mr. E. B. Scott.

6 July 1875.

2078. From what ports have you usually shipped?—From all the coal-shipping ports, that is to say all the ports from which steam coal is shipped.

2079. Both in the North of England and in South Wales?—Yes.

2080. And from Birkenhead?—Yes, but principally from South Wales.

2081. You have paid some attention to the question which is referred to this Commission for consideration, viz. the spontaneous combustion of coal on board ships?—Yes.

2082. Will you tell the Commission from your experience what descriptions of coal appear to you to be most liable to spontaneous ignition on board ships?—I think it is more especially the smelting coals that are shipped for the west coast of South America that are liable to take fire; it is in those coals that we have noticed the greater number of burnings.

2083. Have you any details or particulars of any cases of such coal taking fire spontaneously?—Not of smelting coal; we have never shipped smelting coal ourselves; our experience has been almost exclusively in steam coal.

2084. Have you known any instances of steam coal having taken fire?—Yes.

2085. Will you give the Commission the particulars of any such cases?—The first case of which we have record is that of the "Mary Shepherd," in the year 1852. She loaded a cargo of Swansea coal. The coal was brought up to London at the time when the railway traffic in coal from South Wales to London was just beginning to be developed, and was shipped in the West India Dock. She went on a voyage to Shanghai; we traced her to the Straits of Sunda, and after that she was burnt somewhere in the China Sea.

2086. Have you any details of that casualty?—The vessel was originally classed A1. at Lloyd's for 10 years; and in 1852, when the shipment was made, she was four years old. She was a sailing vessel, built of wood, and believed to be tight. Her builders' tonnage was 550, and her registered tonnage 629. The coal was Resolven coal, from the Resolven colliery, and it was hand picked. The ships' hold was ventilated by a wooden trunk alongside the keelson, and two or three shafts thence to the hatchways. It is believed that the fire originated in the fore-hold. The coal had been on board at the time of the burning from four to five months. It was brought by the Great Western Railway from Swansea, to Bull's Bridge, near Brentford, and was conveyed thence by lighters to the West India Dock. It was a considerable time on the road; longer than would be the case at the present time. The coal was put on board from lighters brought alongside, and was lowered into the hold by baskets. The weather was wet during the loading. No record was kept of the weather during the voyage. The cargo was in the course of its transit from Swansea exposed to the weather to a considerable extent, and it was exceedingly wet at that time. With regard to indications of the cargo being heated before the fire broke out, there were hot decks for some time before the fire. With regard to whether the hold was completely filled up to the hatches, we cannot say exactly, but most probably it was not filled up to the hatches. The only suggestion that we ever heard made with regard to the cause of the spontaneous combustion was that the coal was shipped wet. At that time the subject did not attract the attention it has since done.

2087. Did you consider that the ventilation in that case had anything to do with either checking, or promoting the combustion?—At that time we did not. We thought that to ventilate was the proper thing, but it was entirely the owner's own act; that cargo was on his own account; we made no suggestion on the subject, I think.

2088. Have you any other case?—The next case we had was in the year 1855, that of a vessel called the "Robert Watson." She was built in Newcastle, in 1839. At the time of her being laden, on the 22nd October, 1855, she was classed at Lloyds Æ1. She was laden with 554 tons of Coed Talon steam coal. She put into Queenstown from stress of weather, where a portion of the cargo was landed while the damage to the ship was repaired. On her arrival at Constantinople the cargo was reported to be "heated, and "both bad and dangerous, full of iron and sulphur." This was shipped for the Admiralty, and I find that some communication was made to the Admiralty upon the report which came from Constantinople, but I cannot trace what the explanation given was. The letter-book says simply, "I have the honour to enclose "letter from shipper on the subject," without giving the particulars. That cargo was condemned and was sold there (at Constantinople). If I remember rightly the vessel was somewhat charred by the fire.

2089. Do you attribute that combustion to any special cause?—Coed Talon is a coal which we have always had some doubt about.

2090. Because it contains much pyrites?—Yes, that is the idea we have had of it always, but I could not positively say that that was the cause of the state of the Robert Watson's cargo.

2091. Was the ship ventilated?—I do not know.

Then again, during the years from 1857 to 1863, we shipped 372,000 tons of coal altogether, principally for Her Majesty's service, the Imperial Marine of France, and the Peninsular and Oriental. The bulk of the coal was steam coal, principally from Wales, but a portion was gas coal. We gave no instructions about ventilation, and we had no case of explosion or combustion reported during that period.

2092. Do you remember what coal that was?—I could not give you the names of the coals; they were the ordinary Cardiff steam coals on the Admiralty list at that time. They were all first-class coals; Nixon's Merthyr, Fothergill's Aberdare, Davis's Merthyr, Ocean, Nantmelyn, and others. During this period, from 1857 to 1863, all the ships carrying the quantity of coal I have mentioned were accounted for, except the "Marlborough," the "George Bradford," and the "Middlesex," which were missing, and the "Cassange" which was known to have been burnt. The "Marlborough" was a new high-classed British ship, which was loaded on the 24th of April 1875 with a cargo of Buddle's West Hartley steam coal for Shanghai. She is supposed to have been lost in a typhoon after passing the Straits of Sunda. The two other vessels, the "George Bradford" and the "Middlesex," were despatched to Halifax in January 1862, at the time of the "Trent" affair. They went away unusually early, and they were supposed to have foundered soon after leaving Cardiff, because another vessel named the "Force," that went away at the same period foundered also, but the crew were saved. The only case of burning that we know of out of all those shipments was the "Cassange," a vessel belonging to Messrs. James Thomson and Co., of Billiter Square. Her cargo consisted of 534 tons of Parson's Abbey Graigola coal, and it was shipped on account of private merchants for St. Helena. The bill of lading is dated Swansea, October 1863. She was 369 tons register, built at Sunderland in 1854, and classed at Lloyd's A 1 for 10 years. She was burnt on the way; I do not know at what particular part of the voyage. That carries us up to 1863. Then in the years between 1864 and 1874 we shipped 304,405 tons. That makes a total of nearly a million and a half of tons shipped over sea in the period I am speaking of; that is to say from 1854 onwards. All the vessels carrying these 304,505 tons, and also the coasting vessels, were accounted for and need no remark, except the "Princess Alexandra" and the "Pocahontas." The "Princess Alexandra" was a steamer laden in 1868 with 723 tons of unscreened Londonderry gas coal for Limerick; an explosion of gas took place in that vessel off Dover; the ship was set on fire and otherwise damaged, and some of the crew were injured and killed. About 100 tons of coal were taken out of the ship, and she went on and discharged the remainder of the cargo at Limerick.

2093. (*Dr. Percy.*) What was the name of the coal?—It was unscreened Londonderry gas coal from

Mr. E. B. Scott.

6 July 1875.

the Londonderry collieries. Then the "Pocahontas" was loaded with 1,580 tons of Hastings Hartley. That coal was shipped for Bombay under contract for the Council of India, and was shipped under the superintendence of Captain Steinson the inspector in the Tyne district. She was an American ship of 1,112 tons register, and at the time we took her she was classed in Veritas 5/6 1-1. She sailed from the Tyne on the 13th of July 1874, and was abandoned on the 10th September in latitude 20° South, and longitude 33° West. We had from the master a letter from which I have here an extract which I will read. He writes thus to Mr. David Brown who was the broker, "I arrived home all right two weeks ago. Four "Boston ships have been burnt this season within "two months of each other, and the accounts given "are about alike as to the cause of the fire. My experience, so far as regards ships taking fire is, the "coal heats, and being more or less sulphur in it of "course it ignites. In most every case ships have "taken fire in the hatchways where the fine coal is. "If ships could be loaded so as to avoid the fine "coals collecting in the hatchways, and some means "taken to prevent the coals breaking up, I do not "think fire would occur. I would not advise loading "the ship too quick; we was loaded in three days. "The coal should be perfectly dry and *not fresh* "*mined.* The only way that I know of, is to prevent "the fine coal accumulating in any place, and if "any ventilators is put in the hatches, I would "advise to put in as many as possible; say not less "than four in each hatch, in each corner; by that "way you separate the fine coal and it cools "quicker. One ventilator in my opinion is of no "account. I would platform the ship fore and aft, "so to give circulation of air under the cargo. Some "means must be taken to prevent the coals from "heating. I could not suggest anything different, "except loading the coals in large casks. Quite an "excitement is created here in the insurance com"panies; some of the offices will not take a ship with "export coal at any rate; some have raised the rates, "as it would not pay to keep ships insured carrying "coal at the present rates." Then I have extracts from the log book, which give more details. The first entry from the log book bears date July 26th (13 days after sailing), when squally weather was experienced, and the ship laboured heavily. Then, on August 30th, 48 days after sailing, there is this entry: "An unusual "strong smell of gas was noticed in the fore between "decks at 5.30 a.m. At 7.30 a.m. blue smoke was "seen coming from the port side. The hands were "set to clear away and put coal in 'tween decks. At "the depth of six feet the heat and smoke prevented "further work. Water was thrown down, and about "15 tons of the burning coal jettisoned. When about "two feet from the keelson, the smoke stopped, and "no more burning coal was found." Then, on September 8th, nine days later, there is reported "A strong "smell of burning coal and a light grey smoke. This "smell continued throughout the night all over the "ship; and then a blue smoke was observed coming "out of the after hatch. On the following day, Sep"tember 9th, the smoke increased, and more coal was "jettisoned till the hands got down to the 'tween "decks, when the heat and smoke prevented further "work. The hatches were then closed and the ship "squared away for Bahia. On the next morning the "smoke increased, and the water in the main tank "became very warm. The fire therefore must have "been in the lower hold somewhere aft of mainmast. "On the following day, September 11th, as the smoke "was coming out of the hatchway in dense volumes, "and the coals were heard 'cracking as if the flames "'might break out any minute,' the 'Pocahontas' was "abandoned. At 4 p.m. the flames burst through the "after hatch, and after burning fiercely until midnight "the vessel sank on the 60th day after sailing."

2094. (*Chairman.*) That is the last case you have?—Yes. The casualties that have happened among our shipments, which have amounted to a million and a half tons of coal since 1853, have been comparatively very few; it was not till we came to the year 1874 that we had any case of a serious character, namely, the "Pocahontas," and that ship was loaded with a coal in which we should never have expected such a thing to take place. I never heard of such a thing before as "Hastings Hartley" taking fire.

2095. In one passage of the letter which you read from the captain of the "Pocahontas" he speaks of the insurance offices at Boston being alarmed at the large number of casualties in coal-laden ships; is it your experience that of late years the percentage of cases of spontaneous combustion in coal-laden ships has increased?—Yes.

2096. And the effect has been to alarm the insurance offices both here and in America?—Yes.

2097. Have the premiums risen?—Very much. I should describe them now as being quite "fancy" rates.

2098. To what do you attribute that increase in the percentage of cases of spontaneous combustion?—I am quite at a loss to explain the cause of it.

2099. A great many causes have been suggested. By some it has been attributed to excess of ventilation, and by others to absence of ventilation. Have you formed any opinion on that point?—The opinion I have formed is that a ventilated ship is certain to be destroyed if combustion be once set up.

2100. You are averse to ventilation?—Yes.

2101. By ventilation you mean ventilation through the coal?—Yes.

2102. You would keep the surface of the coal ventilated, would you not?—As often as the weather would permit.

2103. So as to carry off the gases?—Yes, but that we have given so little heed to, that with the exception of telling the master to keep his hatches off in the first instance for 48 hours, we have never thought it necessary to give any special instructions either in the case of our own ships or in the case of any that we have chartered.

2104. As regards ventilation through the coal, you have formed a distinct opinion that ventilation through the coal is prejudicial?—Yes.

2105. Have you formed any opinion whether the increased number of these casualties is due to a different method of conveying the coal to the ship being adopted, or to a more rapid shipment of it, or any cause of that kind?—The only conclusion to which I can come, (but that to my mind is not satisfactory,) is, that in consequence of the increased cost of labour there has not been latterly the same care exercised that there was formerly in taking out the pyrites—in cleaning the coal.

2106. Do you attribute the whole or the majority of these casualties to the presence of pyrites in the coal?—I could not say that that is a positive conclusion to which I have come, but it is the only conclusion I have been able to come to.

2107. The captain of the "Pocahontas" speaks of the mischief arising from the accumulation of large quantities of small coal—is it your impression that small coal is specially liable to spontaneous ignition irrespective of the presence of pyrites?—I think it is; from its lying so much closer together—that is a condition which seems to favour the production and spread of combustion.

2108. Have you formed any view as to the special liability of particular seams of coal to casualties of this kind?—No; our opinion is adverse to North Wales coal and to the smelting coal of South Wales.

2109. But there is no special seam of South Wales coal which appears to be more dangerous than another, as far as your experience goes?—No, we do not know from what seams coals are shipped; we simply take a man's coals; he mixes them according to his own convenience. We only know the pit that the coal comes from, not the seam.

2110. Have you any experience of any special liability of north country coal to spontaneous combustion?—No; the only case we have had was the case of the "Pocahontas."

Mr.
E. B. Scott.

6 July 1875.

2111. You have formed no conclusion as to the special liability of particular classes of north country coal to spontaneous combustion?—No, our evidence is rather negative than otherwise on the subject.

2112. (*Mr. Young.*) You said that you disapproved of ventilators altogether?—Yes, I think ventilation insures the destruction of the ship when combustion is once set up.

2113. You mean ventilation by wooden ventilators? —By the wooden ventilators which are usually used.

2114. Could not a ship be ventilated with metal ventilators?—Yes, she could be; but I think that the ventilation would tend to produce the destruction of the ship as I have already explained.

2115. Have you ever given any instructions, or have you ever known of any instructions being given to test the heat of the coal by the thermometer during the course of the voyage?—No, I have not. We have never given any instructions ourselves with regard to ventilation; our ships have been small ships, and we have shipped our cargoes in the usual way without ventilation.

2116. It appears that during the year 1874 there were more cases of spontaneous combustion than usual. Do you think that arose in any way from the ships not perhaps paying so well, the cost of them being greater than usual, insurances being higher, and captains not being so careful to stick to their vessels than at other times?—No, I have not the slightest idea that that would have anything to do with it.

2117. Do you find that more vessels are lost when they cease to pay than when they are paying?—That does not come within the range of my experience.

2118. In 1874 there were more cases than before—you do not think that the inference to be drawn from that is that the vessels were not paying the shipowners?—I have not any idea of any connection between the two things.

2119. (*Mr. Cory.*) Do you think, as far as your experience as a shipowner goes, that the captain of a ship knows anything about the insurance at all?—Frequently he does not.

2120. Do you yourselves inform your captains that your vessels are insured?—We say this—it is almost a stereotyped form—"The ship is insured, principally "in clubs, but on all occasions you are to please to "bear in mind that you are to act as if we were not "insured."

2121. (*Mr. Abel.*) You stated that you entertain a decided opinion that ventilation is prejudicial to the safety of a coal cargo, can you give a precise reason for that opinion?—I said this, that where combustion is set up I think the effect of ventilation is to insure the destruction of the ship; that is, it soon becomes unconquerable.

2122. You draw a distinction between the effect of ventilation as promoting combustion or heating when once it is established, and as giving rise to the first development heat?—Yes, I should say it would tend to prevent heating in the first instance, but if it is not successful in preventing the heating, then it insures the destruction of both ship and cargo.

2123. You think if it were possible to have a sufficiently efficient mode of ventilation it would be decidedly safe to adopt such a system of ventilation, and that it would tend to prevent spontaneous heating?—If you could ensure a sufficiently efficient mode of ventilation, but the question is how to ensure it.

2124. With regard to the condition of the coal as loaded, that is to say the size of the coal, do you believe that is a matter closely connected with the question of ventilation?—Where there was a large quantity of small coal I think it would be more likely that there would be impurities in the coal.

2125. It is not because you think that the coal would be less ventilated where it was small than where it was large that you consider it would be more liable to ignite spontaneously, but because the small coal contains more impurities?—I think the two things come in; there would, in the first place, be more impurities in the small coal than in the large, and next, from lying so close together, the effect would be more rapidly to increase combustion.

2126. I understand that an accumulation of small coal is caused, in a great measure, from the manner in which the coal is loaded on board ship; that it collects at the hatches, where the coals become more or less broken up?—Yes.

2127. Would there be more impurity in that coal because it happened to be in small particles than if it were in large lumps?—The impurities, in the way of pyrites, would be picked out of the large lumps when it could not be seen in the small; but the accumulation of small coal in the hatchway would arise from the fall of the coal in that particular spot, and there, I apprehend, there would be a want of ventilation, from the coal lying more closely together, and it would be there that combustion would be likely to take place.

2128. The effect due to the smallness of the coal in the hatchways would be an effect apart from that due to impurity of the coal?—Yes

2129. In the single case of explosion which you referred to, was there any damage done?—The ship was set on fire by it.

2130. Was the coal set on fire?—Yes, the coal was somewhat burnt—nothing to speak of; it was left behind in order to lighten the vessel.

2131. Was the vessel ventilated?—No, she was a steamer. She was loaded in a few hours, and there was no arrangement for ventilation.

2132. Was that vessel overloaded?—No. I forget her tonnage now, but she only carried 720 tons of coal. That was about her average cargo. She belonged to a company in Limerick, and she went round from Sunderland to Limerick. It was off Dover that the explosion took place.

2133. (*Dr. Percy.*) Are some smelting coals according to your experience more liable to spontaneous ignition than others?—We are not shippers of smelting coal.

2134. You expressed an opinion that such coal was more liable to spontaneous ignition than any other kind of coal?—Yes.

2135. You do not know whether certain kinds of that coal are more liable to spontaneous ignition than other kinds?—No.

2136. With regard to the presence of pyrites in such coal, have you any experience upon that point? —No, we have not.

2137. You spoke of a cargo of Coed Talon which was shipped in the "Robert Watson," which afterwards took fire, and which you said was full of pyrites. Was there any Admiralty inspection of that cargo?—No; that was before the Admiralty inspection took place. The Admiralty inspection was not established till 1859, and that casualty happened in 1855.

2138. Have you any personal knowledge yourself of any case of spontaneous ignition—have you watched the conditions under which such spontaneous ignition has occurred?—No, I have never had an opportunity of doing that.

2139. Have you any experience of the effect of the atmospheric temperature in promoting spontaneous ignition?—No.

2140. Do you think an elevated atmospheric temperature would be likely to promote ignition?—As a matter of theory, I should say so.

2141. With regard to the cleaning of coal from pyrites, is not it the case that very frequently coal contains pyrites in pretty large quantities which is not in lumps which could be picked out?—I believe so.

2142. Have you any experience with regard to the spontaneous ignition of such coal as that?—No.

2143. (*Mr. Duncan.*) Your experience would lead you to say that the best class of steam coal, when it is well cleaned, is not liable to spontaneous ignition at all?—That is the result of my experience.

2144. Upon the question of ventilation, I suppose your opinion is not based at all upon scientific considerations; that is to say, you do not consider whether the pyrites derives oxygen from the air

Mr. E. B. Scott.

6 July 1875.

passing through it or otherwise ?—No, it is not based upon that. We do not go into the scientific part of the question.

2145. You think if a ventilator were put into the coals, and the coals were set on fire, it would act as a chimney, and therefore would cause the fire to burn fiercer ?—Yes.

2146. You do not base your judgment as to the advantage or disadvantage of ventilation on any scientific considerations ?—No ; it is a sort of rule of thumb decision that we have come to upon the matter.

2147. (*Sir George Elliot.*) I think I remember your name as a buyer of coals for more than 20 years in the north of England ?—My firm and our predecessors have been buyers for more than 30 years.

2148. And you say you have purchased a million and a half of tons ?—Yes, since the year 1854 Mr. Thomas Gillespy and ourselves have shipped nearly a million and a half tons.

2149. What proportion of those coals would you take from the north of England ?—In the first period, 1854, 1855, and 1856, I should say fully half; subsequently it would be about two thirds Welsh coals, and one third north country.

2150. Out of all those shipments since 1854, how many cases of spontaneous combustion have you had in north country coal ?—The "Mary Shepherd" was before that date; that was 1852; that was Welsh coal. The next case, the "Robert Watson," was Coed Talon, North Wales coal, then the "Cassange," was South Wales coal. The only cargo of north country steam coal was the "Pocahontas."

2151. You have been shipping from the Tyne during a period of 20 years, about a third of that 1,500,000 tons of coals, that is to say 500,000; and you have only had one instance of spontaneous combustion in north country coal ?—Yes.

2152. And I understood you to say that you thought that casualty might have been due to the regular system of cleaning coal not having been attended to ?—That was the idea I formed about it as a matter of theory.

2153. As to ventilation, you do not seem to attach much importance to ventilation as a protection against spontaneous combustion ?—No ; we have never taken any precautions of that sort during the whole of that time.

2154. You have carried all this large quantity of coals up to 1874, shipping a great variety of north country coal from the Tyne ; and you have had no instances of spontaneous combustion except that one of the "Pocahontas ?"—That is all.

2155. And that was Hastings Hartley ?—Yes.

2156. Coed Talon you say contains rather a large proportion of pyrites ?—The report that came to us was, "Heated, and both bad and dangerous; full of iron and sulphur." That is the report of the Admiral. I believe it was Admiral Stewart.

2157. With respect to the case of the "Princess Alexandra," there was no spontaneous combustion there ?—No ; that was simply a case of explosion.

2158. In the case of the "Pocahontas," which loaded with Hastings Hartley, how many days was she out before the spontaneous combustion took place ? —48 days after she sailed there was an unusually strong smell of gas ; nine days later there was a strong smell of burning and a light grey smoke.

2159. Does anything occur to your mind that you would suggest with a view to prevent the occurrence of these casualties ?—No ; I have not been able to come to any satisfactory conclusion about the best way of preventing them.

2160. (*Chairman.*) Upon the whole you would recommend that coal cargoes should not be ventilated through ?—Judging from experience I come to that conclusion.

2161. As to the method of shipment, there are several methods in force in the north, at Liverpool, and in South Wales. There is, first, the common shipment from the tip, and, secondly, shipment by boxes ?—That is almost abandoned in Wales.

2162. Then there is a third plan of shipping by barrows ?—They ship by barrows at Birkenhead.

2163. And also in bags occasionally ?—That plan may be adopted in shipping coal for smelting purposes. I have no experience of that.

2164. Have you formed any strong opinion as to the advantage of one system over another ?—No ; I think looking at the peculiar quality of the coal, each mode seems to be well adapted to the particular coal. For instance, in the Welsh coals, there is a careful letting down of the coal by the tip, which slopes down to the ship and forms a screen when required. After the appointment of the Admiralty inspector, which was in 1862, we began to double screen, that is to say, to screen at the time of actual shipment, the small coal being taken away. That system has been given up of late and now we ship generally single screened for the Admiralty.

2165. The coal going from the tip with a heavy fall ?—No, not with a heavy fall ; it goes down the same incline, but there is no screen to take the small coal away.

2166. Do you think it desirable that there should be the least possible fall into the hold ?—Certainly.

2167. It is not very material which plan you adopt provided that result is arrived at ?—Quite so.

2168. (*Mr. Vivian.*) You mentioned one case of Resolven coal having fired, have you shipped other cargoes of Resolven coal ?—Yes, but generally speaking only coast-wise ; it is a very tender coal. We have shipped it largely principally to Devonport dockyard, and as far as Gibraltar, but I do not think any further. I believe it has been shipped over sea, but not by us.

2169. (*Mr. Icely.*) You were speaking of coals on Admiralty list. I presume the varieties on that list are coals of which the Admiralty approve ?—Yes, for their particular purposes.

2170. Have they a list of the coals of which they disapprove ?—Not that I am aware of. The condition of the Admiralty contracts was "that the coals to "be shipped were to be of such and such descriptions "at the option of the Lords Commissioners of the "Admiralty." Practically we knew that for certain purposes Resolven would do, and we knew equally that for certain other purposes we could not send Resolven, but must ship other coals named. At times the then Storekeeper-General used to come down with his big hammer, and by ordering "Nixon's navigation," for which we had to pay a heavy price, remind us that he, and not we, held the option of selecting the coal to be shipped.

2171. (*Chairman.*) That system is not in force now ?—No.

2172. (*Mr. Duncan.*) Putting coals on the Admiralty list amounted to this, did it not, that the owner of a particular colliery submitted his coals to a test, and if they went through the test satisfactorily to the Admiralty he was allowed to put the coals upon the list ?—Yes, they were then put on their list.

2173. As a rule it was the parties who owned the coals who submitted their coals to the proper test, and if they passed such test, they were allowed to be put on the Admiralty list ?—Yes, the Admiralty kept the control in their own hands as to what we should ship. Resolven would answer the purpose if it was to be used in Devonport dockyard, for instance ; but for over sea we should have had to take a higher class of coal.

2174. (*Sir George Elliot.*) The Admiralty did not shew any caprice in the matter ; any person who had a suitable coal, applied to have it tested, and if it came up to the test, it was at once placed on the list ?— Yes, there was nothing capricious about it.

2175. (*Mr. Young.*) Have you ever known a case of spontaneous combustion in a store of coals on shore ? —Yes, in the case of gas coals at Limerick, and also at depôts abroad. I have heard of it.

2176. In those cases were the coals exposed to the weather ?—Yes.

2177. I understood you to say that you thought that coal shipped wet was more liable to take fire than

Mr. E. B. Scott.

6 July 1875.

coals shipped dry?—That is the conclusion I have been compelled to arrive at.

2178. Would not it then be probable that if great quantities of coal were stored in the open air they would be liable to spontaneous combustion?—Yes, and it frequently takes place. I have frequently heard of cases of spontaneous combustion of coals stored in the open air.

The witness withdrew.

MR. JOHN GLASBROOK examined.

Mr. J. Glasbrook.

2179. (*Chairman.*) You are a colliery owner and mining engineer at Swansea?—Yes.

2180. Have you been engaged in shipping coal many years?—Yes, upwards of 30 years.

2181. What descriptions of coal have you been shipping?—Steam coal, mining coal, and house coal. We have only shipped one cargo of smelting coal, that was to the west coast of South America.

2182. Can you give us any information with regard to the liability of particular descriptions of coal shipped at Swansea to take fire spontaneously?—There are only two that are sure to go without spontaneous ignition, those are the 4-feet vein and the 6-feet vein.

2183. The other seams you look on as dangerous?—Yes, they contain impurities. We know that some coals will even take fire on the wharf if kept in too great a quantity. In fact if you have only 10 tons of coal from some of the veins it will take fire; that is the case with coal from the Cistern. I have proved it myself.

2184. (*Mr. Vivian.*) What do you say to the 5-feet vein?—The 5-feet vein is very bad.

2185. What do you say to Hughes's?—Hughes's vein is better than the rest, with the exception of the 6-feet. Hughes's is the next best to the 4-feet and the 6-feet; the 3-feet is very clean, but there is something in it that would deter shippers from shipping it.

2186. (*Chairman.*) You are speaking of Swansea coal?—Yes. This (*producing a diagram*) shows all the veins. This is the 4-feet, that is a good vein. Then here you have the 5-feet which is not a good vein. This is the 6-feet, which is a good vein; and this (*pointing to Hughes's*) is good if it is worked clean. I do not know much about the others. We own about 16 ships, and whenever No. 1, No. 2, or No. 3 Rhondda has been shipped it has taken fire.

2187. What experience have you personally of cases of spontaneous combustion?—One of our ships took fire last year. That was named the "Alpha."

2188. That is the only case of which you have personal experience?—Yes.

2189. In the evidence you have given you have been speaking generally as to your knowledge of the different coals of the district?—Yes.

2190. You also said that you had personal knowledge of coal taking fire on the wharf?—Yes, coal from the 5-feet vein. The Forest colliery has taken fire with us. Coals from the 6-feet and the 5-feet mixed together have taken fire. If you put any 5-feet with anything else there is a danger of its taking fire.

2191. You could put your finger on certain descriptions of coals and say, "These are unfit for shipment for a long voyage"?—Yes, large might go very well, but through and through will not.

2192. There are certain descriptions which you would say could not be safely shipped except for a short distance?—Yes, some of them will go a short distance safely, but some of them I would not trust for five days or seven days.

2193. From what seams would that coal be?—The seams above Hughes's, the Cistern, the Slatog, and the Bodor, that coal is very unfit to go anywhere, there is such a mixture of pyrites and shale in it, shale is the most dangerous thing of any, it contains so much oil and it gets heated. There are veins of coal containing small rods of small slaty stuff, and that breaks up with the small coal, and it is liable to take fire.

2194. What in your opinion are the causes of spontaneous combustion?—Impurities in the coal such as shale and dirt and earthy matter.

2195. Shale and earthy matter and pyrites?—Yes. and what is called "mother of coal" it is very good to burn, it makes very good coke.

2196. (*Dr. Percy.*) It is almost like charcoal?—Yes. I have some specimens of coal here. This (*producing a specimen*) contains a great deal of what they call "mother of coal" that is No. 3 Rhondda. This (*producing another piece*) is a piece of coal without any impurities whatever in it; that is sure to go without ignition, that is from the 6-feet vein.

2197. (*Chairman.*) Do you observe that these casualties have increased lately?—Yes, on account of the men not working the coal clean.

2198. Is that the only reason of the increase?—That is one of the principal reasons why there have been so many cargoes taking fire lately, that we cannot get the men to work the coal clean. They say, "If it does not suit you we will leave it."

2199. (*Dr. Percy.*) There seems to be pyrites in that coal which you say would be sure to go without ignition?—That is fat, I do not think there is any quantity of pyrites in it.

2200. (*Chairman.*) You say that one of the principal causes to which you attributed the increased number of casualties lately is the carelessness of the men in not working the coal clean?—Yes, people have been shipping coals that they would not ship at other times.

2201. The rise in the price of coal has induced the colliery proprietors to ship inferior coal?—Yes, they would ship coal which they would not have shipped at other times.

2202. Is the risk of spontaneous combustion taken into consideration, do you think, by persons shipping inferior coal?—The shippers do not care much what they take so long as they can insure the cargo, the shipowners have to look to that; we only take the 4-feet or the 6-feet in our ships.

2203. You consider that there was greatly increased carelessness in this respect while the price of coals was high?—Yes.

2204. Now that coal has fallen are shippers more careful?—Yes, they will not take any sort of coal now.

2205. Have you formed any judgment as to the advantage or disadvantage of ventilation in coal ships?—I believe separation is better than ventilation, I mean keeping the coal in compartments, small cargoes are not so liable to ignition as large ones. It is just the same as in the case of a large rick of hay, a large rick of hay is more liable to take fire than a small one when the hay is damp.

2206. You mean separation in the ship itself by the coal being placed in separate compartments?—Yes, I should divide the coals into compartments by a three-inch plank or something like that; copper ore vessels are fitted up with trunks and those trunks could be made into separating apparatus very well.

2207. Has that been practically done?—I do not think so; they take no such precautions generally.

2208. That is the precaution which you would take?—Yes, to separate the ship into three or four compartments, that would be in the case of coal which was liable to ignite spontaneously. There is some coal that does not require anything.

2209. As to the coal that would be liable to ignite, you would take that precaution of dividing the ship into compartments?—Yes, and ship the coal dry.

2210. As a shipowner you would limit your shipments to those two veins which you have described?—Yes.

2211. And you would not ship any coal from any other veins?—No, I would not take a cargo of any other description, we do not ensure our ships, and we are obliged to be very cautious.

2212. Have you studied the different methods of

Mr. J. Glasbrook.

6 July 1875.

shipping coal ?—There are many modes of shipping coal. I ship my coal in boxes by the steam crane. That is a very good mode of shipment.

2213. That is an expensive method, is it not ?—No I think we save in labour after all.

2214. It does not add to the costs of loading ?—No, I do not think it does.

2215. Will you describe that method ?—Here is a box about a ton weight that is drawn up by a steam crane and dropped into the hold of the vessel; then they knock the bottom of the box off and the coal spreads away without any pressure to speak of instead of being dropped down and pounded as it is by the tipping process.

2216. So that the coal does not fall far ?—No; and the trimmers move it away as it falls.

2217. That is really on the whole not more expensive than the common method ?—No, I do not think it is.

2218. Summing up the remedies you have suggested, they are these. Only to ship coal which is not liable to ignition from the seams you have mentioned (that is speaking of Swansea coal); secondly, not to ventilate; and, thirdly, where the coal is liable at all to ignite, to divide the ship into compartments; and, fourthly, to lower the coal in boxes, trimming the coal at the bottom and so avoiding any fall ?—Yes, I would not object to those large shoots that they have for shipping coal, because the coal goes in as easily as by our boxes.

2219. That is to say the shoot which goes down actually into the hatchway ?—Yes, the coal drops by degrees.

2220. (*Mr. Vivian.*) You would fill up the hatchway by means of boxes ?—I should prefer to fill it up by boxes if possible, especially in the case of smelting coal.

2221. (*Chairman.*) Those are all the suggestions you would make ?—Yes.

2222. Do you think any of them should be enforced by law, or would you leave it to the shippers ?—I think you might very well leave it in the hands of the shipowners and the persons who ship the coal, but I believe it would be very beneficial if you could compel the men to work the coal clean. You have been legislating all for the men and the rest for the masters lately.

2223. You think something ought to be done in the other direction ?—I think so. We take care that the working people have their food unadulterated, and they ought to give us coal without adulteration where it is possible to be avoided.

2224. (*Mr. Vivian.*) You are working the 5-feet vein yourself, I believe ?—We are working it at Forest.

2225. And you contemplate working it again ?—Yes.

2226. So that the evidence you have given in regard to the 5-feet vein is against your own interest, you being yourself a proprietor of a colliery on that vein ?—Yes.

2227. Have none of the coals wrought from the 6-feet vein in collieries to the westward of Swansea, and shipped to the west coast of America fired ?—None, if they have been shipped alone. Sometimes they smuggle some of the 5-feet and some of the 3-feet vein with it, and then it is sure to take fire.

2228. (*Chairman.*) Who smuggles those coals in ?—The colliery proprietors; sometimes they are short of the other coal.

2229. (*Dr. Percy.*) Can you tell the coal when you see it ?—No; you must watch it, the 3-feet is very clean, and so is the 5-feet sometimes, but still there is a great deal of alum in the 5-feet.

2230. (*Mr. Vivian.*) The water coming from the 5-feet is very bad, is it not ?—Yes.

2231. (*Dr. Percy.*) Very bad for steam boilers ?—Yes; it will eat a hole in a shovel in a night.

2232. (*Mr. Duncan.*) That is from the alum contained in it ?—Yes.

2233. (*Mr. Vivian.*) The price of the 5-feet, the 6-feet, and the 3-feet is the same, is it not ?—Pretty much the same.

2234. So that the only object would be to fill up the ship ?—Yes, when they were short of coal. There is a great demand for the 6-feet, and it is better than the other, but they will sometimes ship the others with it. I know Mr. Sterry has been short of the 6-feet, and he has plenty of the 5-feet.

2235. You have never known a case of the 4-feet firing ?—No.

2236. There is very little of the 4-feet shipped over sea, is there not ?—They used to ship a great deal of it from Primrose to South America; there is very little of it left.

2237. You mean that quality. There is plenty of the steam coal left ?—Yes.

2238. You have shipped large quantities of the 5 feet for short voyages, have you not ?—Yes, to Cornwall for instance.

2239. It is lying in heaps in Cornwall without firing, is it not ?—Yes, mixed with other coal in layers.

2240. Have you ever known any case of patent fuel firing ?—No.

2241. Do you believe it possible for patent fuel to fire ?—No; unless it fires from an explosion of gas the same as steam coal.

2242. It will not spontaneously ignite ?—No; you can build it up in chimneys and separate it in any way you like. I never heard of a cargo of patent fuel taking fire.

2243. Nor of explosion ?—No.

2244. We have had some evidence as to Tyr Edmund taking fire ?—That is sure to take fire if mixed with Abbey Graigola.

2245. What vein is that in the Swansea coal measures ?—That is above the 6-feet.

2246. That would come under the class of veins which you mentioned as likely to take fire ?—Yes, it is sure to take fire if mixed with the 6-feet; it is full of impurities.

2247. The Abbey Graigola is much the same, is not it ?—The Abbey Graigola is the 6-feet vein; that is clean and always goes without danger.

2248. They work the Tyr Edmund with it ?—Yes, they ship it with it.

2249. So that if you heard of Abbey Graigola taking fire you would think that some Tyr Edmund had been shipped with it ?—Yes, there is no mistake about it.

2250. You would recommend that coals from veins which are known to be spontaneously ignitable should not be shipped for long voyages ?—Yes; I should keep them at home for the manufactories and ship the others.

2251. You spoke of the Rhondda veins being liable to spontaneous ignition, can you mention any specific cases of Rhondda coals having fired ?—I believe that every ship that went from Cardiff with Rhondda coal Nos. 1, 2, and 3 during the scarcity of coal took fire. Four cargoes of Cardiff coal ignited last year, viz., "Lady Heathcote," 527 tons; "Admiral Fitzroy," 550 tons; "Ermenigilda Donovara," 1,100 tons; and "Clothilde," 746 tons.

2252. Shipped on long voyages for smelting purposes ?—Yes.

2253. That is not steam coal ?—No, steam coal goes safe enough; that is shipped large, and there are no impurities in it.

2254. Does it increase the cost of shipment much to fill up the hatchway by means of boxes in the first instance ?—No, nor even with baskets.

2255. Having filled up the hatchway by means of boxes to a certain extent you go on tipping in the ordinary manner ?—Yes, because the men can shift the coals.

2256. Have you seen the mode of shipment adopted in the New Alexandra docks at Newport ?—No; I believe it is pretty much the same as that adopted at Swansea at the new drops. They have a crane at Swansea and I see the same at Newport.

Mr. J. Glasbrook.

6 July 1875.

2257. Your recommendation would be that to each drop there should be a jib attached?—Yes; I would have the first 100 tons shipped by means of boxes, it would not increase the cost much.

2258. To fill up the hatchway?—Yes, that would save the coal from breaking so much.

2259. With regard to the fires which you say occurred from Rhondda coal, did those fires occur previously to the last three years or during the last three years?—I believe there was none of it shipped before the last two or three years. I believe the shipments of coal to South America were confined entirely to Swansea and Liverpool.

2260. It was the want of coal at Swansea that drove shippers to Cardiff you think?—Yes, that drove them to take Rhondda coal from Cardiff; I believe the Morfa went very well.

2261. You never heard of a case of the Morfa taking fire?—No.

2262. The other veins in the Rhondda valley except those you mentioned are not liable to catch fire?—I never heard of one.

2263. (*Mr. Cory.*) Is it a common thing in your district for the same colliery to work the coal from several seams?—Yes; they bring up the same shaft the produce of the several seams, but generally they have separate tipping places for it.

2264. The coals from all those various seams come up at the same time?—No; not in the same tram.

2265. At the same time?—No; they will raise what they call "a party," that is 10 or 12 trams in one vein, and then they will raise a "party" in another vein.

2266. Do not you think that if a colliery was in full work there would be a considerable chance of a mixture taking place under such circumstances without the coal owner intentionally mixing the coals?—They never do mix them, they keep them separate the 3-feet vein generally is all sold for the works, it works very small, and the other works very large; the large is shipped and the small is sold to the works.

2267. Do you think in the case of a considerable pressure of business the people at the colliery could succeed in keeping the produce of each vein separate?—As far as I understand they do it. I always do it when I work coal. I have been working many seams in the same pit, and always separated them.

2268. (*Mr. Vivian.*) You can not only keep the produce of each vein separate, but you know what man has worked each tram, do you not?—Yes.

2269. And you know from what portion of the ground it comes, so that if you have different royalties you can distinguish the one from the other?—Yes, the name of the cutter is on the tram, and they tip one man's coal into one shoot and tip another man's coal into another.

2270. (*Mr. Cory.*) When the coal is delivered down those shoots it goes into trucks?—Yes.

2271. What sized trucks?—10-tons trucks.

2272. You do not consider that the coal is liable to get mixed?—No, unless it is done on purpose.

2273. (*Mr. Fenwick.*) I understand that you do not insure your ships?—No, we do not insure them, we put so much by for an insurance fund; *i.e.*, the Swansea Merchant Shipowners Company's ships.

2274. Have you always done that?—Yes, after we had 10 ships. We acquired our ships gradually, and when we acquired 10 we did not insure.

2275. You have not insured since the premiums have risen?—No, nor before. We did not insure after we had the first 10. The "Alpha" luckily was insured, she was one of the first 10, the others have gone safely.

2276. As a matter of business do you gain by insuring yourselves?—Yes, at the present freight it would take all the profit. We get enough in the year out of the 16 to purchase a new ship to replace one if she is lost.

2277. (*Mr. Icely.*) What is the general impression at Swansea with regard to the ventilation of ships, is it in favour of it or otherwise?—The overlooker of our own ships, Captain Pear, thinks it is better not to ventilate, he thinks it is better to select your coal and not ventilate; if you ventilate in good coal you do no harm; if you ventilate in bad coal you assist the burning after it once ignites.

2278. You are in favour of no ventilation at all?—I am in favour of separation.

2279. Do not you consider surface ventilation at all necessary?—Yes, I think it is advisable to keep the hatches off as much as you can.

2280. Would you do anything else in the way of ventilation besides keeping the hatches off?—I would have a pipe something like what you have for the ventilation of steamers.

2281. That is only to prevent danger from explosion?—Yes, it is almost in the bottom that the spontaneous ignition begins.

2282. Do you not think that pipes passing through the cargo and leading to the surface would be an advantage?—I do not think they would do any harm. You could then ascertain if there were any heat in the coal. I should like to have one or two to test whether there was any heat. You could do that by lowering a thermometer. I do not think it would do any harm, in fact I think it would do good.

2283. Have you given any instructions to the captains of your ships with regard to taking the temperature of the cargo?—I have not the management of the ships. We keep a manager and a secretary.

2284. You leave it entirely to them?—Yes, we have an experienced man as manager. He has been 25 voyages to south America, and he is a very experienced man, and a very intelligent man. We leave it all to him.

2285. I understand you that you have had no casualties among those 16 ships except the one you mentioned?—Where there was a mixture of the 4-feet and the 5-feet coal.

2286. Your impression is that that was the cause of the casualty?—We are certain of it, because if this 6-feet is shipped by itself it never takes fire, either wet or dry. It cuts in cubes and does not produce so much dead small dust.

2287. (*Mr. Young.*) Did all your 16 ships go to the west coast of South America?—Yes, with the exception of one of them, I think, which went to China or the West Indies.

2288. You have shipped coal in those ships at all periods of the year?—Yes, every month of the year.

2289. You are very careful as to the kind of coal you allow to go into your ships?—Yes, we only allow the 4-feet or the 6-feet to go into our ships.

2290. Because you do not insure?—Yes.

2291. Is it within your experience that during the two or three years when the price of coal was high, Nos. 1, 2, and 3 Rhondda was often shipped in other vessels?—I have not heard of it.

2292. I understood you to say that those coals had been mixed with other coals?—No, I said the 5-feet has been mixed with the 6-feet in some cases.

2293. Did the shipowners know in such cases that the colliery people were putting on board the 5-feet instead of the 6-feet?—No, but they know it now. A cargo of Rhyd-y-ffad went on fire lately.

2294. Your experience has led you to this conclusion, that if everyone was his own insurer there would be no necessity for legislative interference, every man would look after himself?—Yes; we shall never ship a cargo again without seeing what we get.

2295. You say that the coal from the Cistern veins is apt to take fire even at the pits' mouth?—You might have 10 tons down out of the pit to-day, and to-morrow you could not put your hand in it, it would be so hot.

2296. If that were shipped even for a short voyage it would be liable to take fire?—It would take fire before the ship was loaded. That is the Cistern vein, the next but one above the Hughes's vein.

2297. Have you ever known great quantities of coal lying on shore to take fire?—I never saw any coal take fire but the 5-feet.

Mr. J. Glasbrook.

6 July 1875.

2298. (*Mr. Vivian.*) Is anyone working the Cistern?—Yes, Mr. Daniel.

2299. He works it for his own works, does he not?—He does not ship any.

2300. (*Mr. Young.*) Supposing a lot of coal to have a certain quantity of this 5-feet in it it would probably take fire?—Yes, that is to say, supposing it had some of this Cistern in it. The 5-feet is not so bad if it is worked clean.

2301. If any of this Cistern coal got into a lot of any other coal it would be likely to spontaneously ignite?—Yes.

2302. That is your experience?—Yes.

2303. (*Mr. Abel.*) With regard to these veins which you have described as being liable to ignite spontaneously, do you ascribe that liability to the character of the coal or to the impurities it contains?—Both. The coal contains impurities not so much in the way of shale and dirt as other impurities.

2304. Are the impurities in those particular coals so distributed through the coal that no amount of cleaning removes them?—They are in the nature of the coal.

2305. What are those impurities?—I believe sulphur and phosphorus.

2306. You said that the presence of shale and porous coal like "mother of coal" was more dangerous than pyrites?—That "mother of coal" is very dangerous, because it goes small amongst the coal, and if it is wet or damp it will heat. There is a great deal of vegetable matter in the "mother of coal, and there is a great deal of oil in shale.

2307. Some of those coals which contain a large quantity of shale and "mother of coal" do not contain much pyrites?—That is so; you can hardly sit in a room where this Cistern vein is burning, there is such a strong smell of sulphur.

2308. That shows that there is a great deal of pyrites in the Cistern vein?—Yes.

2309. Is there much shaly material in that vein?—Yes, there is some of that too.

2310. In some of the other coals the pyrites is small, but the shale and porous coal is considerable?—Yes, if you look up some of the knobs you would find that almost half would be shale.

2311. (*Dr. Percy.*) You say that if you stored 10 tons of that Cistern vein coal it would fire?—Yes; I might put 10 tons of it down to-day, and to-morrow I could not put my hand in it.

2312. Is that a hard coal?—No, not very hard.

2313. It will not stand weathering I suppose?—It will get as white as lime if you put it in the atmosphere a short time.

2314. Have you put your tongue to the coal to ascertain whether it tasted of iron?—No.

2315. Have you ever examined the white stuff that appears on the coal?—Yes, there is a great deal of salt in that, I think, and alum.

2316. Have you ever put your tongue to it?—There is a great deal of alum in the 5-feet.

2317. What leads you to say that there is phosphorus in the coal?—My impression is that the Cistern vein coal contains a great deal of phosphorus.

2318. Is that an impression merely, or a conclusion to which you have come from any chemical examination?—I have not had it analysed.

2319. (*Mr. Duncan.*) You have been asked whether the shipowners could prevent these bad coals from being put on board; many of them would not have the same facility of preventing it that you have?—No, not those at a distance unless they had an agent.

2320. If they had an agent he might be a man that they could not depend on?—Yes.

2321. The underwriters sometimes raise a question with regard to the coal a shipowner is proposing to take in his ship?—Yes.

2322. You mentioned that the coals from some of those veins, for instance the 4-feet and the 6-feet, might go safely if they were clean worked?—Yes, Hughes' vein is as pure as any vein if properly worked, but there is a bed of rubbish on the coal and another in the seam, and the bottom sometimes is bad while at other times it is good.

2323. Both the colliery owners and the miners are perfectly cognizant of those bad parts?—Yes.

2324. And as a rule the colliery owner does not want to have those bad parts wrought along with the others, but the miners are not careful to avoid working those bad parts?—If we could prevail on the men to work the coal clean the coal would be marketable in any case, that is the Hughes vein.

2325. It is a fair and legitimate inference that a good deal of this spontaneous combustion has arisen from the people at the colliery mixing this 5-feet coal which you think dangerous along with the 4-feet and the 6-feet when there was great pressure to get coal?—Yes.

2326. They were of the same value, and therefore the owner without thinking of the risk of spontaneous combustion would think that he might as well have the ship filled up instead of detaining her by which he might be incurring 20*l.* a day demurrage?—That is very often the case no doubt.

2327. You think if pure steam coals were shipped at Cardiff in a proper state the risk of spontaneous combustion would be very small indeed?—There would be no risk at all.

2328. And the same with regard to coal shipped at Swansea?—Yes; I never heard of a cargo of steam coal taking fire at all.

2329. It is the smelting coal that you have been speaking of as being so liable to take fire?—Yes; I am shipping a great deal of steam coal, but I never heard of any of it taking fire.

2330. You hold that even the small coal which is shipped for smelting purposes would be safe enough if taken out of the 4-feet and the 6-feet?—Yes, there would be no danger. I would insure a ship directly that carried it.

2331. (*Sir George Elliot.*) Do you sell that smelting coal unscreened?—No, it is through and through.

2332. There is no small taken out?—No.

2333. You take care that you have nothing but the 4-feet and the 6-feet?—We will not take any coal from Swansea but the 4-feet and the 6-feet.

2334. Is the same care observed by other shippers as well as yourselves as to that?—There has been no care taken lately. When the demand for coal was so great people had to take what they could get, and I think that has been the cause of so many ships taking fire lately.

2335. You attribute the large percentage of cases of spontaneous combustion of late years first to the carelessness of the workmen in not cleaning the coals, and secondly, to the promiscuous mixing of the 4-feet, and 6 feet, and the 5-feet?—Yes.

2336. And I suppose you would say that the masters are culpable as well as the men in not taking care that the coal is wrought clean?—No doubt the masters ought not to have shipped coal from those veins where the coal was liable to ignite spontaneously.

2337. Have you considered whether it would be practicable to carry out the suggestion you have made of having the coal shipped in compartments?—I think it could be carried out.

2338. Take a 1,500 ton ship; how many compartments would you have?—900 tons would be the utmost that a ship would carry going to the west coast of South America.

2339. You are speaking of the west coast of South America trade?—Yes.

2340. What is your idea of the size of the compartments that would ensure more security?—I should think in a space the size of this room I would have four or five compartments.

2341. That is to say you would have quantities of 200 or 300 tons together?—Yes, I would put planks between the coal as it was put in.

2342. Supposing you had one or two partitions in a space the size of this room, would not the pressure be the same as you have now?—There would be a separation of the pressure just the same as in the case

Mr. J. Glasbrook.

6 July 1875.

of a rick of hay. You may make a rick of hay into two or three compartments, but if you make a large rick, and if the hay is not good, it is sure to take fire; whereas if you have a small rick it is not so liable to ignite spontaneously.

2343. Shipping by boxes you would limit to merely filling the hatches with them; it is not practicable to adopt that system on a large scale where great despatch is needed is it?—For large coal I would not care to do it but it would pay the coal buyer to have it done that way because there is a great deal of breakage in dropping coal down 20 feet.

2344. Ventilation you do not attach much importance to except as a safeguard against explosion?—I would not object to it; I would prefer to ventilate the ship, though there is a difference of opinion about it; provided there was a large hole made in the cargo it would be a good thing.

2345. You have been a shipowner and sending coals to the west coast of South America for a long time?—Yes.

2346. How long is it since you arrived at the conclusion that the 4-feet and the 6-feet were the only two safe seams from which to ship coal?—It is notorious everywhere in the district of Swansea.

2347. That must have been the result of experience from other coals having been found unfit for a long voyage?—Several coals have taken fire when people have been speculating on coal from other seams. There is the Avon Vale, that is known to have taken fire. I would not ship a cargo of it. They shipped one or two cargoes, and they took fire, and I told them they would be sure to get them on fire.

2348. With regard to the Rhondda coal, there is a large quantity of Nos. 1, 2, and 3 shipped, you said that in your opinion all coal from those veins must fire?—That is from what I have heard, it is a good coal for cokeing and house purposes, but I do not think it would go on a long voyage if shipped through and through.

2349. (*Mr. Duncan.*) From what you have suggested in reference to separating coals into different parcels, I gather that you would consider it better to have a coal-carrying vessel built with two or three decks rather than having 24 feet depth of hold, the whole of the cargo lying on one bottom?—Yes, that would be as good as anything; 24 feet is too great a depth unless the coal is very clean and dry. I think what you suggest would be a very good arrangement.

The witness withdrew.

Captain John Galloway examined.

Captain J. Galloway.

2350. (*Chairman.*) You have been master of different merchant ships for some time?—Yes; for about 20 years.

2351. And you have had some experience in carrying coal?—Yes, I have been carrying coals 16 years in the Indian trade.

2352. Have you had any experience of cases of spontaneous combustion or explosion in coal-laden ships?—I have very little experience in that respect, it has only been in the last six or seven years that I have even seen any signs of heating.

2353. Within the last six or seven years have cases of heating come under your observation?—Yes.

2354. I think you had one very serious case in a ship you commanded?—Yes, the "Malabar."

2355. Is that the only ship you commanded in which such a casualty ever took place?—Yes.

2356. In what year was that?—In 1870.

2357. What coal was it?—It was fron Langley Mill coal-pit. We shipped it in London.

2358. You sailed from the port of London with that coal?—Yes.

2359. Do you know in what part of the country Langley Mill pit is?—I do not know. The coal was shipped from lighters which came alongside.

2360. You do not know whether it was north country coal?—No.

2361. Your ship was an iron ship?—Yes.

2362. Of 1,200 tons register?—Yes.

2363. And you carried under 1,300 tons of coal?—We had 1,274 tons on board.

2364. How many days were you out when the casualty happened?—About 36 days.

2365. Where were you bound for?—London to Batavia.

2366. Can you tell us anything about the circumstances of the casualty?—After having been out about 36 days, on one Saturday night, for about the first time all the while that we had been out, the hatches were put on. We generally had the hatches off in good weather all the way, but I told the mates that night to secure the hatches as I expected a change of weather, so they put the hatches on; and on Sunday morning about 5 o'clock the second mate took off the hatches, and he came and called me and told me that there was smoke coming up through the centre of the coals in the main hatchway. When I saw that, I altered the ship's course and put back for Rio Janeiro, and threw 50 tons overboard, and when I had put that 50 tons overboard the flames burst all over us. We set the pumps to work all that night and all the next day. We had two force-pumps and a little donkey engine, and we put the hose through under the 'tween decks; the 'tween decks were all burning, till at last the flames got halfway up the mainmast. Then we were obliged to close up the hatchways, and to put sails on the top of the hatches, and chains on the top of the sails to keep all close. That went on for two days, during which time I had the crew put in the stern. An American ship came up, and the crew said they would not stop any longer; they said that the flames might burst up at any moment. I wished them to stay that night, but they would not, so we went on board the American ship, and in about an hour after the hatchways blew right up and the mainmast went over the side.

2367. The ship was a total loss?—Yes.

2368. Do you know in what state that coal was taken on board?—I was informed afterwards by my mates that the coals were taken on board wet; that the lighters had been making water, and the coals were in a wet condition.

2369. How were they shipped from the lighters?—By baskets.

2370. Without any great fall?—They had no fall at all.

2371. Do you attribute the heating of that coal to its being shipped damp?—Yes, that is what I attribute it to.

2372. You do not know whether that particular description of coal was peculiarly combustible?—No. It was small bad coal that they were shipping at first, and I called the attention of my owner to the fact then; he made some remonstrance, and they seemed to be better after that.

2373. When you say they were bad you mean they were of inferior quality?—They were small.

2374. You had not it in your mind at the time that they were dangerous?—No.

2375. How was your ship ventilated?—Right along the keelson fore and aft, and then up and down the three hatchways.

2376. What was the size of the ventilating passage or chamber along the keelson?—About 18 inches square.

2377. Was it on both sides of the keelson?—It was put over the keelson on the keelson itself.

2378. Is that the only case you have personal knowledge of?—The only one. I have loaded coals since. I loaded coal in Dundee in another ship, and while they were loading it came on very wet and I stopped loading for two and a half days, I would not allow the coals to go in at the time it was raining.

2379. And you had no trouble in the case of that cargo?—No.

2380. You have had an experience of 20 years as master of a ship?—Yes, I have been taking coals out to the East Indies 16 or 17 years.

Captain J. Galloway.

6 July 1875.

2381. During all that experience the case you have mentioned is the only case of spontaneous ignition that you have had ?—Yes.

2382. What is your impression about ventilators, do you fancy it does any good ?—I fancy it does a great deal of good. In the case of the "Malabar" the ventilators were partly smashed when the coal was taken in. I cleaned the fore and aft ventilators, but the main one was not properly cleaned, or we would have observed the fire sooner.

2383. You are not one of those who look on ventilation as useless ?—No, I think it is very much required. I would put a platform underneath if I had my will in any ship taking coals on board, about 2 feet above the ceiling with holes in it, so that there might be a current of air underneath.

2384. In your 20 years' experience have you had to do with all kinds of coals ?—Yes, but they have been mostly Scotch coals shipped on the Clyde. I have taken them from Wales, but only to the West Indies and Mauritius, when they have been about two or three months on board.

2385. Notwithstanding they were all that time on board you did not find that they became heated ?—No.

2386. (*Sir George Elliot.*) You say you have been engaged for 16 or 17 years in carrying coals. For how many years have you adopted any system of ventilation in your ships ?—They never were ventilated till about 1867 I think.

2387. For about 8 or 10 years you were navigating vessels without ventilation ?—Yes.

2388. And you never had any casualty of any kind ?—No.

2389. Seeing that you went 8 or 10 years without any mishap, would not that lead one to infer that there was no necessity for ventilation ?—My opinion is that the cause of that unanimity from danger in former times was that the coals were put in bins, that is to say, large places at the coal pit, and they would lie perhaps 12 months exposed to the air before they were put on board ship, but now they take them out of the coal pits and put them on board ship directly, so that the gas does not have time to escape. The class of ships now conveying coal have been generally much increased in tonnage, consequently greater masses are carried in one bulk, formerly 500 to 1,000 tons may be taken as the extremes generally of foreign cargoes: they now range from 1,200 to 2,500 tons cargoes, and consequently require more care and ventilation through the greater mass of the cargoes.

2390. You mean that up to 1867 you used to take the coal on board your ship out of stock and not out of the pit ?—Yes.

2391. That would only be during a portion of the year; you would not always be taking out of stock, would you ?—I expect they were mostly taken out of stock in those days; they used to be in great heaps, and where those coals were lying any length of time exposed to the air the gas would escape.

2392. Did you ever know any Scotch coal to take fire by spontaneous heating ?—Yes; several of those ships that left Dundee with me last year caught fire.

2393. I mean previous to 1867 when the system of ventilation was not known ?—There was one in 1868, the "Duke of Portland" took fire; she loaded in Ardrossan, and the crew came into the Mauritius when I was there.

2394. Was she ventilated ?—No. That was the first one carrying Scotch coal that I remember.

2395. During the first 8 or 10 years of your experience you never ventilated ?—No.

2396. And you never had anything happen to you ?—No.

2397. Is that a condition that can be much improved on do you think ?—I do not know whether the different quality of coal may have anything to do with it, yet the greater bulk of the cargoes has I believe much to do with it.

2398. As to the "Malabar," which did take fire, the men lifted the coals by baskets from the barges and put them into the ship ?—Yes.

2399. When the men lifted them up to the hatchways did they drop them down ?—They capsized them down.

2400. Therefore they would fall 18 or 20 feet ?—They would at the commencement.

2401. And they were wet you say ?—Yes, the mate told me that the lighters were making a great deal of water.

2402. (*Chairman.*) Have you any general suggestion to make to the Commission on the subject of their inquiry ?—No.

2403. (*Mr. Duncan.*) With regard to the coals shipped in the "Malabar," you do not know from what district of county they came ?—No.

2404. What dock was she in when she loaded those coals ?—The Victoria dock.

2405. The coals did not come to the ship in trucks ?—No, in lighters.

2406. Do you know where the lighters loaded ?—No.

2407. Do you think they loaded close by the Victoria dock, just outside ? — I could not say where they loaded.

2408. (*Mr. Young.*) You have no personal knowledge of any cases of burning except this one ?—No.

2409. And you have carried a great many cargoes of coal ?—Yes.

2410. Mostly Scotch coal ?—Yes.

2411. Both from Glasgow and Dundee ?—On the first voyage I went with the "Malabar" I wished to get the ship ventilated. My owners said, "No, it was of no use to ventilate Scotch coal," I said I thought it was useful, so I got them to adopt the system of ventilation; it was on my third voyage bound to Batavia in her that this casualty happened. I went out and came back all right on the two first voyages, and I was taking a cargo of coals out on the third voyage when the fire took place.

2412. (*Mr. Icely.*) Speaking of your system of ventilation you described a trunk running along fore and aft near the keelson, was there any communication with the deck from the trunk ?—Yes, the up-and-down ventilators went into the horizontal trunk. The ventilators went down fore and aft.

2413. So that there were two currents of air, one coming to the foremost part of the ventilating trunk and the other to the after part ?—The horizontal ventilator went right fore and aft along the keelson; and then there were ventilators up and down in the three hatchways which went into this fore and aft ventilator.

2414. Those upright ventilators were uptakes for the gas ?—Yes.

2415. You had an in draught at the after part of that trunk that was laid horizontally and you had an in draught at the fore part ?—Yes.

2416. And those perpendicular or vertical trunks were the exits for the foul air ?—Yes.

2417. (*Mr. Fenwick.*) You said you were 36 days out when you first discovered indications of heat ?—Yes.

2418. Whereabouts were you then ?—In 29° south and 30° west.

2419. You say you had your hatches off most part of the time ?—Yes, till that night.

2420. You had ordered the hatches to be put on that night on account of the changeable weather ?—Yes, when you come outside 30° south you may expect gales of wind.

2421. (*Mr. Cory.*) Those particular coals which were shipped in the "Malabar" could not have been very fresh from the colliery, could they ?—I could not say.

2422. You loaded in London ?—Yes.

2423. There are no collieries in the immediate neighbourhood of London ?—No.

2424. The coal must have come some distance ?—Yes.

2425. It must have been shipped into the lighters in London ?—Yes.

2426. Therefore it could not have been very fresh

Captain J. Galloway.

6 July 1875.

from the colliery?—I have no information as to how long it was out of the coal pits, but it was taken on board in a wet condition.

2427. Those coals must have come some distance, while many of the other cargoes which you have carried safely would probably have come very quickly from the colliery?—They may have come quickly from the colliery, but they would have been put out in bins at the colliery and exposed to the air a long time before shipment.

2428. You look upon that exposure of the coal to the air at the colliery before shipment as an element of safety?—Yes.

2429. Have you any reason for coming to that conclusion?—There are so many coal ships that take fire nowadays when they do not keep the coal in bins at the collieries as they used to do before being shipped that I come to that conclusion; that is the only thing I go by.

2430. (*Chairman.*) You do not draw your conclusion from the case of the "Malabar," but from general observation?—Yes.

The witness withdrew.

Captain JAMES CAWKITT examined.

Captain J. Cawkitt.

2430*a*. (*Chairman.*) You are manager of the Salvage Association at Liverpool?—I am.

2431. And chief surveyor to the local underwriters?—Yes.

2432. How long have you held that position?—About 12 years.

2433. Previous to that you had been master of a ship in the East Indian trade?—In the East Indian trade, the China trade, and the Australian trade.

2434. In both capacities you have had some experience in connection with the shipment of coal?—My experience with regard to the shipment of coal since I left the sea has been chiefly confined to Liverpool and Birkenhead, but I have heard a great deal about the shipment of coal from other parts from time to time.

2435. You have studied the question from information that has reached you more than from your actual personal experience?—That is so.

2436. Have you arrived at any opinion with respect to the greater or less liability of particular kinds of coal to ignite spontaneously on board ship?—More particularly of late we have found that the number of cases of burnings has increased chiefly in the Lancashire coal, smelting coal going out to the west coast of South America.

2437. At Birkenhead you ship exclusively North Wales and Lancashire coal?—Yes.

2438. You do not ship any Derbyshire coal there?—No.

2439. Nor any Staffordshire? — There may be some, but it is chiefly North Wales and Lancashire.

2440. Have you noticed any increase in the casualties in the shipments of North Wales coal of late years?—Not so much of late years.

2441. But you have observed a considerable increase in the casualties in the Lancashire coal?—Yes.

2442. Could you describe to the Commission the particular seams or the particular denominations of coal which appear to you to be more liable to spontaneous combustion than others?—I do not think I could give you the seams. I think they have been chiefly Barnes' shipments of Lancashire coal and one or two others, which Mr. Rundell gives in his list. I could not tell you the particular seams or the pits. I can only say, speaking of shipments of Lancashire coal generally, that we have noticed that there have been more fires in them of late than in others.

2443. Do not the underwriters endeavour to trace home the particular description of coal in which the greatest risks seem to occur?—Yes.

2444. Have they not succeeded in that?—They have the statistics which Mr. Rundell has embodied in his pamphlet; many of his statistics are got up from our surveyors' reports, and they are recorded in the pamphlet which he has published.

2445. All you are able to say is that in coal raised from certain districts in Lancashire the risk seems to be much greater than it used to be?—Yes.

2446. How would you describe those districts?—I should call them the Lancashire coal districts.

2447. Is the result of that that the premiums charged by the underwriters on the shipment of Lancashire coal has risen?—Not alone on Lancashire coal.

2448. Is it higher than it was on Lancashire coal?—Yes.

2449. Much higher?—Yes.

2450. Have you been able to arrive at any opinion as to what the cause of the increased liability to fire may be?—My own opinion is that a great deal of it is attributable to the shortness of time that elapses between the time of the coal being wrought from the pits and its going into the ships, and perhaps from an inferior kind of coal being shipped.

2451. The shortness of time would cause the coal to be more gaseous?—The air would not have the same opportunity of percolating through it and permitting the gases to escape before the coal was put into the ship's hold?—No.

2452. That would point rather to explosion than to heating and spontaneous combustion?—This coal is of an explosive character. I do not profess to have a thorough scientific knowledge of coal; but the impression upon my mind is that the more coal is liable to spontaneous combustion the less it is liable to explosion, and the more liable it is to explosion the less liable it is to spontaneous combustion. I am not positively certain that that is so.

2453. Is it your judgment that it is rather in the direction of heating than in the direction of explosion that the recent increase of accidents has taken place?—I think so. In the whole of my experience I have only had one case of explosion, and that occurred at Birkenhead about six years ago. That was in the case of a vessel called the "Mary Amelia," which loaded South Wales steam coal from the Dyffryn steam colliery. Our surveyor had a note that she had loaded a cargo of South Wales coal. There was no ventilation. They closed the hatches on the Saturday, and on the Monday we heard that an explosion had taken place at Birkenhead, and it turned out that it was in this vessel. It appears that the hatches having been closed from Saturday night, the ship keeper went on board on the Monday morning, and went into the store-room with a naked light, and the whole deck blew off. The man was badly injured, and a paper was found in his pocket warning him against the explosive character of this coal, and telling him not to take a naked light down below. That has been the only case of explosion in the neighbourhood of Liverpool that has occurred in my experience.

2454. With reference to heating and spontaneous combustion, have you formed any opinion as to the desirability or otherwise of ventilation?—I am strongly in favour of ventilation, that is to say, ventilation carried out thoroughly and carefully.

2455. Will you describe what system of ventilation you would recommend?—If we could ventilate the whole cargo in a body, so as to admit air through the whole of it, I do not think spontaneous combustion could arise, but perhaps it might be impossible to devise any system of ventilation to do that.

2456. Even though the coal should be small and wet?—I should think if the coal was shipped damp, and it was small coal and in a confined space, firedamp must follow. That would be a very dangerous state of things I think.

2457. In any case you would be for the greatest amount of ventilation possible?—Yes; as a prevention.

Captain J. Cawkitt.

6 July 1875.

2458. What exact process of ventilation would you recommend?—What I should recommend in the first place would be a platform perforated with small holes, laid under the cargo, so as to raise the cargo and allow a current of air underneath it, and then ventilating shafts up each hatchway, communicating for and aft with the top of this platform.

2459. How high should the platform be above the keelson?—In a wooden ship it need not be as high as the keelson, but I should say it might be about 18 inches from the ceiling to the top of the platform.

2460. Carried the whole way fore and aft?—Yes; as far as the coals were carried. Those ventilators should be carried up above the deck with those bell-mouthed tubes upon them, so that they could be turned to the wind to enable a current of air to go down under the platform.

2461. Irrespective of ventilation, have you any suggestion to make with regard to precautions which are now not taken, and which you think ought to be taken?—The great point is the shipping of the coal in a good dry condition, and every care being taken that air is admitted into the hold by every possible means. I think it is a most important point that the coal should be shipped dry.

2462. (*Sir George Elliot.*) How long have you had the superintendence of the shipment of coals at Liverpool and Birkenhead?—I have not the special superintendence of the shipment of coal more than any other cargoes, but in the course of our duties we note how coal ships are loaded for the information of the underwriters.

2463. You are employed by the underwriters?—I am chief surveyor to the Liverpool underwriters, but we are daily in communication with gentlemen who superintend specially the loading of coal for the Peninsular and Oriental Company, the East Indian railways, and so on.

2464. How long have you held that office?—12 or 14 years.

2465. I suppose in your experience there has been a much larger number of cases of fire in coal-laden ships these last two or three years than there had been previously?—There can be no question about that.

2466. Has there been less ventilation the last two or three years?—I think the ventilation has been about similar.

2467. It is not due to any change in respect of ventilation?—No.

2468. What strikes you as the reason for these increased number of casualties?—As I said before, I think the shipment of small coal has a great deal to do with it. It has not been allowed to accumulate at the pits, and then it goes fresh from the pits to the ship. Of late that has been particularly so in consequence of labour strikes, and so forth, and in consequence also of the great demand for coal, and the small quantity ready to ship. That has been particularly so with regard to this smelting coal. I think very inferior qualities and small coal have been shipped.

2469. Have the coals been shipped with more despatch the last two or three years than previous to the last two or three years?—I think they have.

2470. What makes you think so?—Perhaps last year they were not so quickly shipped, but before that there was a very great demand.

2471. Was there not a great difficulty to get coals last year?—Last year there was.

2472. And consequently were not they shipped more rapidly?—The individual ships that loaded would receive the cargoes more rapidly; there were a great number of ships waiting for coal at the time.

2473. Are you aware that no more coal was raised in 1873 and 1874 than previously?—I am not aware of that.

2474. You regard the rapidity with which, during the last two or three years, coals were brought from the pit to the ship as compared with previous times, as one of the causes of the increased number of casualties?—Yes.

2475. Another cause in your opinion is that the coal has been smaller than it was three or four years ago?—I think the Lancashire coal has been smaller.

2476. There has been no change in the ventilation?—No, I think not. We believe in ventilation, and we have tried to get it carried out to the greatest extent of our recommendations.

2477. You said that Barnes' coal was more especially liable to take fire spontaneously?—He is one of the shippers to the West Coast. Several of his ships have been burnt with that description of coal in them.

2478. That is from Lancashire?—Yes.

2479. You cannot specify any particular district?—No; I do not know what mines they came from.

2480. (*Mr. Duncan.*) Did you carry coals yourself when you commanded a ship?—No.

2481. How many years back does your experience go in conexion with the shipping of coals?—12 or 14 years.

2482. Do you think there was as much ventilation 12 or 14 years ago as there is now?—No; I think there is more ventilation now.

2483. Seeing that there is more ventilation now than formerly, might not it be that ventilation does harm rather than good; has that ever occurred to you?—No; I think the number of long voyage coal ships to the east has been increasing of late, and that would account for an increased number of casualties.

2484. If you were told that scientific men who have analysed coals have found that they contain sulphur and pyrites and have ascertained that by allowing a current of air to pass over those constituents the oxygen of the air very likely tend to set the coal on fire, you would probably question the desirability of passing great quantities of air over coal when carried on board ship?—If a fire took place no doubt ventilation would tend to aggravate it, but as a preventitive we believe in ventilation, and further we think that it leads to other precautionary measures. I do not think sufficient care is taken by the captains and officers of ships that load coal. I think they are too careless about it. They do not take the danger of the cargo they are taking on board fully into consideration.

2485. In what way?—I mean in taking precautions. For instance, there are very few coal ships that go away with a thermometer to test the temperature of the coal.

2486. That would not prevent the firing of the coal?—No; but it might forewarn them of danger.

2487. You mean by their not taking care they are not careful to keep their hatchways covered in rainy weather and things of that sort?—I think the principal precautions are required when they are loading the cargo and they ought to be continued throughout the voyage.

2488. It has been stated before this Commission that there are cases where the admission of air would positively tend to put the coals on fire; that allowing a current of air to pass through them would supply to the pyrites contained in the coals the very thing to create spontaneous combustion; has that ever occurred to you?—That has occurred to me; but that is a question for scientific men to deal with.

2489. Further than your own practical experience you have no data upon which to ground your judgment in reference to ventilation being very desirable?—No.

2490. You probably consider that coals emit gases, which gases are inflammable, and that it is therefore desirable to get them out of the ship as quickly as possible. Is that the principle on which you think ventilation is desirable?—The principle on which I think ventilation desirable is that it is desirable to get a current of air through the coal; gas usually accumulates on the upper surface; if the gas accumulates on the upper surface that is a different condition of things to spontaneous combustion; that occurs from firedamp in the ship hold.

2491. (*Mr. Abel.*) You state that coals in which explosions were likely to occur would be less liable to

Captain J. Cawkitt.

6 July 1875.

spontaneous combustion than other coals; have you any facts to support that opinion?—No; it is merely my own opinion and the result of conversation with others. There have been very few cases of spontaneous combustion in shipments of coal from South Wales ports where they ship steam coal of the best character.

2492. Is that coal liable to explosion on board ship?—Yes; I believe the south Wales coal is.

2493. That is only an opinion?—It is only my own opinion.

2494. You also stated that coal coming fresh from the pits was more liable to spontaneous heating than coal which had been exposed, and you thought that the increase in the number of casualties was partly due to that. Is that based upon any facts that you can give the Commission?—That is only a general opinion I have formed.

2495. You also stated that small coal had been allowed to accumulate at the pits and that this had been shipped fresh from the pits to the ships, and you thought that that was one cause of the spontaneous heating. I do not quite understand that?—The small coal would be more liable to generate heat and damp than large coal. Large coal stowed in the vessel's hold would admit air amongst it.

2496. What you really meant was, that the increased number of casualties might be due to shipping a larger proportion of small coal which had been allowed to accumulate. If that small coal was damp it would be more liable to spontaneous heating?—Yes.

2497. You ascribe the increased number of casualties rather to the larger proportion of small coal shipped than to the shipping of it fresh from the pit?—I think it is due to both causes.

2498. Have any facts come within your knowledge which have led you to that conclusion, or is it merely an opinion?—Most of the burnings in the ships we have heard of have been under the main hatch, and the bulk of the burnings have been in vessels that have been loaded under the tips where the coal is broken, and where there has been a lot of small coal accumulating round the main hatchway, and I believe in most instances the fire has been proved to have originated about the main hatchway.

2499. Those casualties have, in your opinion, been caused by the production of small coal by the method of shipping, and not by the shipping of a larger proportion of small coal as such?—That is so to a certain extent, but the action of damp in the case of small coal would be more injurious than in the case of large coal in a confined space.

2500. (*Mr. Young.*) You are practically employed as professional assessor to the underwriters at Liverpool, and you go round to look at the ships for the purpose of seeing that the ships are in good order, and that the cargoes are properly loaded?—Our staff of surveyors do, and I used to do so till lately. I am more in the office now.

2501. Coals of course only come along with other things under your observation?—Yes.

2502. You have not paid any particular attention to coal cargoes?—Yes, as regards ventilation, storage, quality, and quantity shipped by each vessel.

2503. Has your experience led you to warn underwriters against certain classes of coal as being liable to spontaneous ignition when shipped on board vessels?—All that we have been in the habit of doing till lately has been to report that a vessel is loading with a cargo of North Wales coal, South Wales coal, or Lancashire coal, and whether by hand or by tips, without reference to the colliery; but of late, since these burnings have been so frequent, we have been taking notice of the colliery from which the coals have come.

2504. Have you found a marked increase in the number of cases of spontaneous combustion in shipments of coal from Birkenhead within the last two years?—There was a great immunity from fire in coal shipped at Birkenhead till about three years ago. We had scarcely a case of spontaneous combustion in shipments from Birkenhead till three years ago.

2505. Has there been a great increase also in the number of such cases in ships that have gone from Liverpool?—Yes.

2506. Has the increase been greater than in the case of Birkenhead?—Yes.

2507. Your advice to the underwriters would be to avoid insuring ships shipping coal from such and such collieries?—They would notice the facts given in our reports and act upon them.

2508. Has it come within your observation that the class of ships that carry coals from either of those two places has deteriorated during the last few years?—We think they have rather improved.

2509. They are mostly iron ships?—Yes, and large fine American ships.

2510. You do not find so many old-fashioned colonial-built vessels of a low class?—No, not so many.

2511. Do you find that ship owners as a general rule take great pains in the way of seeing how the coals are shipped themselves?—Yes.

2512. Irrespective of you and your surveyors?—I think so. I think every disposition is shown to carry out the recommendations of the surveyors.

2513. They make you welcome on board?—Yes.

2514. (*Mr. Icely.*) Is it one of your requirements that the temperature of the cargo should be taken?—Our surveyors who visit the ship ask the captain before the vessel loads what mode of ventilation is adopted, what coal he is taking, the quantity, and so forth. One of the questions we put is whether he is taking a thermometer with him to test the temperature, if he says, No, we recommend him to do so, and we advise his recording the temperature in the log book each day.

2515. Has it been your custom to ask those questions and to make those recommendations for a long period or a short one?—It has been our custom for several years back. We cannot insist upon their doing what we recommend. We merely advise and suggest.

2516. Within your experience for how long a period has it been considered necessary to ventilate ships?—I think they have been ventilated now as far back as I can recollect, but the mode of ventilation I think has been rather improved.

2517. A system of ventilation of some sort or other has been adopted for a great number of years?—Yes, I think so.

2518. (*Mr. Fenwick.*) You are decidedly in favour of ventilation yourself, and the Underwriters' Association at Liverpool adopt your views in regard to ventilation? — Our mode of ventilation has been adopted by them, and it is understood that most of the ships which they insure are ventilated in that way.

2519. (*Chairman.*) Was coal treated as a specially hazardous cargo till lately?—Formerly I do not think it was.

2520. Was the premium on ships carrying coal higher than upon ships carrying iron?—No.

2521. Now it is very much higher?—Yes.

2522. That is the result of the impression produced on the minds of the underwriters by the casualties in the last few years?—Yes.

2523. Is there any difference in the premium charged on ships going from Liverpool with Lancashire coal and that charged on ships going from Birkenhead with North Wales coal?—No. I think the premiums are generally equal; they have all risen.

2524. Though the risk may really be very different?—Yes.

2525. There is a sort of panic among the underwriters just at present?—There is, in consequence of the frequent burnings of late.

2526. Are the underwriters kept fully informed of all facts tending to show the comparative liability of different descriptions of coal to take fire spontaneously?—The underwriters have Mr. Rundell's statistics before them, and they are guided by those facts in taking risks. We state that a vessel is loading

Captain J. Cawkitt.

6 July 1875.

a cargo of Lancashire coal, and we may state the colliery from which the coal comes. The underwriters are now thoroughly posted in the character of the coal from the different collieries. Mr. Rundell's statistics give the number of burnings, and also the mine that the coal comes from, and the underwriters are posted up in those facts accordingly.

2527. I gather that you merely report what coal it is that is being shipped, and then the underwriters have Mr. Rundell's statistics before them, by which they are guided in fixing the premium they charge according to the denomination of the coal ?—That is so. I believe the premiums are equal all over. I do not think there is any great difference between the premium in the case of one coal and another.

2528. If the premiums are equal all over, and if it has come out before us that there is a very remarkable distinction in the liability to ignition spontaneously between different kinds of coal, one would infer that the underwriters are imperfectly informed with regard to the various characters of the different descriptions of coal ?—I do not think that. I think each underwriter will take his own view. I could not speak with regard to the premiums. I think the underwriters as a body are fully informed as to the dangerous qualities of particular descriptions of coal. Each underwriter, I presume, will act on his own judgment.

2529. (*Mr. Young.*) You say the premiums remain very much the same. Is not it the case that Liverpool underwriters do not underwrite such cargoes as you, from your reports, show to be dangerous, and that those cargoes are not taken in Liverpool at all ? —That rests with themselves. We merely report the facts for them to act on at their pleasure.

2530. They judge of them themselves ?—Yes.

2531–2. I believe that practically they refuse to underwrite risks that you report unfavourably on ?—Yes, I should think so ; some might and some might not.

The witness withdrew.

Captain W. Kennedy.

Captain WILLIAM KENNEDY examined.

2533. (*Chairman.*) You have commanded ships in the merchant service for some years ?—Yes.

2534. You have had considerable experience in carrying coal ?—Yes, a good deal.

2535. About how many voyages have you made with coal ?—10 voyages.

2536. Within how many years ?—18 years.

2537. Have you ever had a case of spontaneous combustion in any of your ships ?—Once.

2538. Will you tell us the particulars of that case ? —My first voyage with coal was in a ship of 1,100 tons, called the "Wallace." I loaded her with coals in Cardiff at the beginning of March 1852 for California. We had to call at Callao for orders, and then we went to San Francisco. The coal was on board for about seven months from the time we loaded till we began to discharge, and though we had no ventilation there were no signs of heating in the ship during the voyage. On the next voyage, in the same ship, I loaded in London, out of barges, and went to Coquimbo, and arrived all safe. On that voyage also she was not ventilated. Then I went out twice with coal to Hong Kong in another ship, a ship called the "India," and she went safe.

2539. Was she ventilated ?—No. The "India" loaded coals in the Clyde, and went to Hong Kong all safe. She was not ventilated, she was only a 550 tons ship ; on both voyages there were no signs of heat at all. I next went out in the "L'Aqouhanna." On her first three voyages we were ventilated, only we had no ventilation along the keelson. It was the stevedore's idea that the large coal might be laid in a rough way fore-and-aft along the keelson and above the keelson about two feet. He did that himself, and when the coal was about 8 feet high we had two ventilators right fore and aft, about 15 inches square, and we had uprights in the fore hatch, the main hatch, and the after hatch ; then we had cross ventilators from those into the uprights, and the ends of those fore and aft ventilators were clear from the coal ; they were away 2 or 3 feet from the coal. That was the system adopted for three voyages. The coals, in the case of those three voyages, were loaded in Birkenhead by barrow, the barrow was tipped wherever it was required without any fall at all ; and then when they came to get within 4 feet from the beams, and they could not work under the beams, they laid a plank on the top of the beams and wheeled the barrows along that way, and then there was only a 4-feet drop. On the last voyage the agent and part owner was in a great hurry, and he would have us go under the tip in Birkenhead. The tip lifts a truck about 15 or 20 feet above the ship's deck, the coal runs in an iron shoot, and by the time it gets into the hold it is smashed up very much, and a large body of small coal always lies where it falls, for the trimmers never think of trimming that, it is only the round coal that they trim. When I saw this I objected to it, and I said "I do not like this small coal accumulating here, and we ought to be careful now that we hear of so many ships taking fire." The agent said "Do you think the ship will be lost through it ?" I said "I would not go so far as to say that, but still I did not like it." We had an extra ventilator alongside the keelson. We had pieces of wood in this way ∧ on each side of the keelson, the lower board was about 3 inches off the skin. Then there would be a ventilator down each hatchway entering into the fore and aft ventilator in the ship's bottom. On this voyage, on account of so much small coal that went in with the tip, I had two tiers of ventilators, one under the beams, and another tier above the beams, there being ventilators into the uprights in each hatch from each of those tiers of ventilators. I could not say exactly the date we left Liverpool, I think it was the 10th or the 15th of October that we left. We found no heat till we got within 500 miles of Bombay. The first indication we had of the heat was seeing the paint beginning to get black, and there was a smell as if coal-tar had been capsized, though there was no such thing in the ship at all. We got the fire hose to work and threw in water, and pulled to in the best way we could. After we had got 2 feet of water in the ship, we got the hose attached to the main pumps and pumped the water out, and then put water down the hold again so as to saturate the coal, but it was all of no avail. After about 50 hours of it we were at last obliged to put the boats out, at about 4 in the morning. We got them victualled and watered, and by the time they were ready it was time to go out.

2540. The ship was a total loss ? — Yes. We were not a mile away from her when the flames burst up the after hatch and the main hatch, and 10 minutes after the mainmast fell carrying with it the mizenmast.

2541. What coal was that ?—I could not say. Our agents could tell probably. It was called North Wales coal.

2542. Considering your immunity from accidents of this kind in your previous voyages, to what do you attribute the casualty which you met with on that occasion ?—To the coal being dropped down from such a height and its being smashed up so that there was so much small coal lying under the main hatchway.

2543. The accumulation of so much small coal produced an unfavourable impression on your mind at the time ; you did not expect to lose your ship, but still you thought it was dangerous for the small coal to be lying there in such a mass ?—Yes.

2544. Do you think that the thorough ventilation which you seem to have exceptionally given to this ship increased the danger, or do you think that it diminished it ?—When the fire did take place it was worse ; it acted as a fan to blow it up.

2545. Do you think it tended to diminish the risk of taking fire originally ?—I doubt it, because I have

Captain W. Kennedy.

6 July 1875.

often carried coals without ventilation at all and no accident has happened with them.

2546. Do you take it to be the bent of your mind from experience that ventilation does more harm than good ?—I do not think it does much good.

2547. What do your owners say about ventilation ?—When I came home one of my owners, Mr. William Ross, of Glasgow, was quite astonished that I did not turn to and bore holes in the ship and let the water run into her in that way, and then pump it out. I said any person while the ship was burning could go down and bore holes, but after the water came to the fire we should get no one to go down to plug the hole.

2548. Do you know what the opinion of your owners is on the question of the ventilation of a coal ship ?—My owners are of opinion that ventilation is beneficial.

2549. What are their instructions ?—It is left to my own judgment. Messrs. Robert Young and Company, of Glasgow, were the principal owners of the ship, and they left it to me to do everything I thought was necessary with the advice of any older hands in the coal trade.

2550. Do you consider it to be the general opinion of those of your experience that in a trade like your own ventilation is beneficial ?—There are a great many that I have known who have had their coal on fire, and whose ships were well ventilated, who have said that they did not think ventilation was of any use.

2551. They would push the hatches off as often as possible, so that any gas might escape ?—We never had the hatches on except when it was raining. Salt water will not make the coal take fire ; it is the fresh water that heats the coal.

2552. When you speak of ventilation, you mean ventilation through the coal ?—Yes.

2553. You do not mean ventilation on the surface ?—I believe it is of great benefit on the surface, because whatever gas there may be it will evaporate through the small openings in the coal.

2554. I take it to be the general effect of your evidence that you doubt the efficacy of ventilation ?—I doubt the practical worth of ventilation at all. The last voyage I took with coals was in the "America" of Glasgow, 1440 tons register, built of iron. We sailed from the Clyde 11th April 1873 with 2000 tons of steam coal, and landed the same at Coconada, without any signs of heating during the whole voyage. No ventilators were used on this voyage ; the owner, John H. Watt, Esq., did not approve of them.

2555. You are strongly of opinion that the lower the fall of the coal when it is put into the ship the better ?—Certainly, you get the coal rounder.

2556. It is your opinion that a large accumulation of small coal in the ship's hold particularly under the hatchways is very dangerous ?—Yes, because on one of my voyages when I got to Bombay there were four ships on fire, they had all got in in time to get assistance and they got the steam pumps from shore to put out the fire, and it was in the after part of the main hatchway that those ships were burning.

2557. Did they load under the tip ?—Yes, those four ships were all from Birkenhead.

2558. (*Mr. Duncan.*) What was the name of those coals which you loaded on this voyage when they took fire ?—I cannot say. They were North Wales steam coal.

2559. Were they as round coals, generally speaking, as you had been accustomed to load from Birkenhead ?—Something the same.

2560. As a rule the coals from Birkenhead are large coals ?—Yes, some of them are very large.

2561. This cargo was not quite so large ?—No, and the coals being so small and having to fall a great height there was a great accumulation of small coal round the hatchways.

2562. Do you think it possible that the coals might have come from East Cheshire and come round to Birkenhead to be shipped ?—They told me that they were North Wales coal.

2563. (*Mr. Young.*) Probably what you would do in future would be to adopt the plan you referred to as having been so successful on board one or two of your ships, that is to say putting the largest pieces of coal all along the keelson, and so creating an internal ventilation ?—That is the way it was done for three voyages.

2564. And it was most successful ?—Yes.

2565. You had no wooden ventilators at all in that case ?—Not to the keelson ; 7 feet above the keelson there were wooden ventilators right fore and aft.

2566. Probably you will continue to adopt that plan in future ?—It was through the advice of older hands in the coal trade that I adopted it, and I may mention that I never found any heat at the bottom of those ventilators.

2567. Did you put the thermometer down from time to time ?—Yes.

2568. Did you register the temperature in the log book ?—Yes ; the greatest heat I have ever felt in all the coal carrying in my experience has been just at the hatchway. You will always feel the heat there, but if you go down you will feel no heat.

2569. Do you mean that you will feel the heat whether the cargo is in a state of spontaneous combustion or not ?—I have always experienced heat at the hatchway even when I have carried the cargo safely and well, and it is the same with a cotton ship. The heat has been so great at the hatchway that you would think the ship was on fire.

2570. It is not peculiar to coal ?—No.

2571. (*Mr. Icely.*) Was this ship when she took fire ventilated in the same way as she had been when she went safely with her cargo ?—She was better ventilated according to the opinion of older hands in the trade than myself ; we had this roofing of wood over the keelson and about 10 inches above the keelson there was a free passage of 3 feet on each side of the keelson.

2572. Did the ends of that horizontal shaft extend beyond the coal on each side ?—They could not go exactly beyond the coal because of the shape of the ship, but round knobs of coal were placed at the ends ; I paid attention to that ; all the large coal was placed round them.

2573. Where was the air admitted to that horizontal shaft ?—From the main hatch and the fore hatch ; upright ventilators went down into this shaft.

2574. Did the upright ventilators have a direct communication fore and aft with the shaft ?—Yes.

2575. (*Mr. Cory.*) I understood you to say that you thought wet would tend to promote heat in a coal cargo ?—Fresh water.

2576. But not salt water ?—No.

2577. So that you would not close the hatches to prevent a little salt water going down ?—No ; unless there is heavy weather we never think of putting the hatches on. If I am not wrong I think the Peninsular and Oriental Company tried an experiment with salt water at Bombay ; they got water carried up by the natives and they saturated the coal with salt water ; they put no ventilators in the stock and there never was the least heat out of the coals at all, but they are very much afraid of their taking fire with fresh water, and I believe they have taken fire on shore at times.

2578. (*Chairman.*) Have you any suggestion to make to the Commission on the subject referred to them ?—I only speak from what I know by experience. I may say that if cotton gets wet with salt water it will heat and be apt to set the ship on fire, but fresh water will not heat it. I was at Bombay when two ships were coming home with cotton bales ; while they were loading the cotton was exposed to heavy rain ; that did no harm, but afterwards when the cotton had got saturated with sea water both those ships took fire.

2579. (*Mr. Young.*) Was there any oil or seed on board either of those ships ?—No ; oil is a bad thing to have on board. I never allow a drop of oil below because there is nothing worse than oil.

The witness withdrew.

Adjourned.

Tuesday, 16th November 1875.

THE RIGHT HON. HUGH C. E. CHILDERS, M.P., IN THE CHAIR.

PRESENT:

FREDERICK AUGUSTUS ABEL, Esq., F.R.S.
RICHARD CORY, Esq.
GEORGE DUNCAN, Esq.
JOHN FENWICK, Esq.
JOHN FERGUSON, Esq.
CHARLES ICELY, Esq.
WILLIAM YOUNG, Esq.
J. M. CARMICHAEL, Esq., Secretary.

Mr. ARTHUR OWEN DAVIS examined.

Mr. A. O. Davis.

16 Nov. 1875.

2580. (*Chairman.*) You attend from the Peninsular and Oriental Company to give us what information the company have as regards spontaneous combustion of coal shipped for their service abroad?—Yes.

2581. Will you tell us in the first instance as to the year 1874, what were the total shipments of different kinds of coal?—In 1874 we shipped by 213 colliers 287,003 tons of coal to various foreign ports. To Alexandria we shipped 6,151 tons, which was carried by nine colliers. To Aden we shipped 60,755 tons by 36 colliers.

2582. Through the Canal?—No, round the Cape.

2583. (*Mr. Duncan.*) Those are coal-laden ships properly speaking?—Yes. To Brindisi we sent 28,862 tons by 27 ships; to Bombay we sent 38,164 tons by 24 ships; to Calcutta we shipped 6,794 tons by 4 ships; to Hong Kong we shipped 19,073 tons by 11 ships; to Malta we shipped 50,932 tons by 47 ships; to King George's Sound we shipped 15,096 tons by 8 ships; to Point de Galle we shipped 28,802 tons by 25 ships; to Shanghai we shipped 4,106 tons by 3 ships; to Singapore we shipped 18,834 tons by 13 ships; to Suez we shipped 4,217 tons by 3 ships.

2584. (*Chairman.*) Did those go through the Canal?—No, round the Cape for ports to the eastward of Suez. To Yokohama we shipped 5,217 tons by three ships.

2585. Can you give the class of coal in each case?—I have not the respective quantities of each description of coal in every case, but I can give the descriptions of coal conveyed to the principal ports. To Alexandria we shipped of Bebside West Hartley (that is Newcastle coal) 1,363 tons, and to the same port of Insole's Merthyr (which is a Cardiff coal) 2,301 tons. To Aden of Bebside we shipped 4,019 tons, of Howard's West Hartley 8,917 tons, of Battersby's North Wales Main 14,316 tons, of Scott's Brymbo (a North Wales coal) 14,937 tons, of Powell Duffryn (a Cardiff coal) 5,992 tons, of Insoles Merthyr 7,136 tons. Then to Brindisi we shipped 19,011 of Powell Duffryn and 6,474 of Buddles' West Hartley (a Newcastle coal); to Bombay we shipped 10,732 tons of Scott's Brymbo, 11,416 tons of Battersby's North Wales Main, and 3,785 tons of Insoles' Merthyr; to Calcutta we shipped 2,186 tons of Powell Duffryn and 1,804 tons of Insoles; to Hong Kong we shipped 3,261 tons of Battersby's North Wales Main, 3,146 tons of Scott's Brymbo, and 5,079 of Powell Duffryn; to Malta we shipped 33,044 tons of Powell Duffryn, and 2,927 tons of Davis's Maestag; to King George's Sound we shipped 5,895 tons of Battersby's, 3,750 tons of Powell Duffryn, and 3,846 tons of Scott's Brymbo; to Point de Galle we shipped 12,822 tons of Insoles' Merthyr, 3,657 tons of West Hartley Main, 4,243 tons of Howard's West Hartley, and 6,005 tons of Scott's Brymbo; to Shanghai we shipped 2,966 tons of Powell Duffryn, and 1,140 tons of Insoles' Merthyr; to Singapore we shipped 12,837 tons of Insoles' Merthyr, and 1,775 tons of Scott's Brymbo; to Suez we shipped 2,860 tons of Powell Duffryn, and 1,357 of West Hartley Main; to Yokohama we shipped 3,345 tons of Powell Duffryn, and 1,872 tons of Insoles' Merthyr.

2586. Will you tell us what casualties you have had, and with what class of coal in each case?—During the year there were three ships which loaded Howard's West Hartley (a Newcastle coal) for Aden. Those three were burnt.

2587. Have you the names of the ships?—The "Euxine" (an iron ship) the "Oliver Cromwell," and the "Calcutta." The "Euxine" had been a Peninsular and Oriental steamer, and after we sold her she was converted into a collier.

2588. (*Mr. Cory.*) At the time she was burnt she was a sailing ship?—Yes.

2589. (*Mr. Duncan.*) Can you tell us in what month of the year those vessels sailed?—The "Euxine" sailed on the 12th of June 1874. The "Oliver Cromwell" sailed on June the 18th, and the "Calcutta" on June the 12th. Then of the ships carrying coal to Bombay there is one missing, the "Nora Græme." She sailed from Liverpool.

2590. (*Chairman.*) In what month did she sail?—She sailed on the 23rd of September.

2591. (*Mr. Icely.*) Have you the description of coal she was laden with?—Scott's Brymbo.

2592. (*Mr. Duncan.*) You have no evidence that she was burnt?—No, we only know that she was lost; at least the underwriters have paid for a total loss. Then in the case of the ship "Ontario," which went with coals to Bombay; her coals took fire when she was just outside Bombay. The Government sent a tug out to bring her into the harbour and it was found that about 100 tons of her coal had been burnt or damaged. At all events we have claimed for 100 tons so damaged. The tug towed her into Bombay.

2593. (*Mr. Icely.*) When did she sail?—I cannot give you the date of her sailing.

(*Mr. Ferguson.*) She sailed on the 6th August 1874.

2594. (*Chairman.*) You may say there were four cases of actual combustion, and one of a ship missing, cause unknown?—Yes.

2595. Do you know anything about the state of the weather when the coal was shipped in any of those cases?—Generally more or less wet. It frequently happens that between the time when the coal leaves the pits and the time it is put on board some of it gets wet.

2596. Do you happen to know how the coal was put on board those ships, whether by tip or barrow? At Birkenhead the coal is invariably loaded by barrows into our colliers.

2597. (*Mr. Duncan.*) When the coal is being shipped have you any one representing you to see that no coal containing pyrites or shale is shipped?—Yes; we have an inspector at the ports of Newcastle, Birkenhead, and Cardiff.

2598. (*Chairman.*) Was the "Nora Græme" loaded at Birkenhead?—Yes.

2599. Where were the "Euxine," the "Oliver Cromwell," and the "Calcutta" loaded?—At Newcastle.

2600. How were they loaded?—I think they were loaded from tips, but I will not be certain. They were all loaded in the Northumberland Dock, and I believe from tips.

2601. Does the Peninsular and Oriental Company impose any conditions as to ventilation?—No.

2602. It is left to the shipowners to ventilate as they please?—The underwriters stipulate in some cases that the keelson shall be ventilated with vertical shafts or with Venetian ventilators to hatches.

2603. But in the tenders the company itself does not make any condition?—No; in fact our inspector at Newcastle, Captain Steinson, who has had a good many years experience, and is a thoroughly practical man, is quite against the system of ventilation from underneath.

2604. You have given us your statistics for the year 1874, have you any similar statistics for previous

Mr. A. O. Davis.

16 Nov. 1875.

years ?—I have drawn up a memorandum which I will read :—

"Memorandum relative to spontaneous Combustion of Coal on Shore and in Bunkers of the Company's Steamers :

"Cases of spontaneous combustion in the company's coal stacks have taken place, but taking into consideration the heavy stocks kept up, and the extremes of heat and moisture to which they are exposed, such instances are very rare. About 10 years ago, a case of firing occurred near the bottom of a large stack of coal at Calcutta, when about a thousand tons of coals had to be removed ; it was then discovered that for a space of about 6 feet square the coal was in a very heated and charred condition. At Aden, in July last, two cases of heating occurred, one in the heart of a stack of North Wales coal, and the other near the surface of a heap of Bebside Hartley (Newcastle) coal. In the course of the last 10 years three or four cases of explosion in the bunkers of the company's steamers have taken place, owing to the *close* covers of the bunkers having been kept on too long ; it is, however, one of the company's standing orders to their chief engineers, that the close covers of the bunkers must only be put on when the decks are being washed, or in very bad weather ; *grated* covers being used on all other occasions, so as to admit of the escape of the gas generated in the coals—(for the same reason it would be well, were the hatches of colliers lifted on all occasions where practicable). In the company's experience cargoes of the South Wales coal are much less liable to spontaneous combustion than either Newcastle or North Wales coal. The arrangements for stacking the company's coal are as follows :

" Malta	In sheds, in the open, and in barges, ready for shipment.
" Brindisi	In the open.
" Aden	Do. do.
" Bombay	Under sheds.
" Calcutta	Do. do.
" Galle	In sheds and in the open.
" Singapore	In sheds.
" Hong Kong	Do.
" Shanghai	Do.
" Yokahama	In floating hulk and in sheds on shore.
" King G. Sound	In floating hulks and in the open on shore."

2605. It would appear that in some places the coal is stacked in the open, while in others it is under cover, the climate in each case being very nearly the same. Is there any particular reason why coal should be stacked differently in the one case to what it is in the other ?—At Aden the land on which it is stacked belongs to the Government, our tenure of the land is very uncertain, and therefore we have not erected any sheds there for coal ; but at Bombay, and Calcutta, and Shanghai, where we have our own property, where the land is either freehold or leasehold, we have run up sheds.

2606. The company do put the coal under cover where they can ?—Yes ; particularly at places like Bombay and Calcutta where the monsoon rains are very heavy.

2607. Can you give us any information for the years before 1874 similar to what you have given us for 1874 as to the number of casualties at sea ?—I have not such statistics here.

2608. Could you furnish us with a table giving the amount of coal shipped to places beyond the equator, the number of casualties, and the description of coal in the carriage of which the casualty occurred, say for a few years past ?—I will do so. I know that 1874 shows a far larger percentage of cases of spontaneous combustion and casualty than any previous year.

2609. (*Mr. Fenwick.*) Are you able to assign any cause for there being so many cases in 1874 as compared with other years ?—I do not know the reason of it. The fact has caused a considerable amount of attention. Some people say the coal is not so well cleaned as it used to be, and so a greater amount of pyrites gets into it.

2610. You are not able from your own judgment to draw any conclusion upon the matter ?—No.

2611. (*Mr. Young.*) You said that you inspected the coal as it went on board, but you did not take any care about ventilation, that that was left to the shipowners ; practically, then, you contract with the shipowner to deliver so many tons of coal at a certain place and you do not care how it gets there ?—Very often it is a matter of difficulty to get tonnage at all, and if we hamper a man with all kinds of restrictions as to ventilation he might not be inclined to take our coals. We naturally conclude that a shipowner will take as much care of his ship as he can.

2612. You do not insure the coal yourselves ?—Yes, we insure our coal and shipowner insures the ship.

2613. You only take such steps as are necessary to satisfy the underwriters ?—Just so.

2614. (*Chairman.*) You do not ensure the coal in a fund of your own ?—No, we ensure it in the ordinary way.

2615. (*Mr. Duncan.*) Probably one of the reasons which would prevent you interfering with the owner as to ventilation wovld be that yoor own inspector in whom you have great confidence thinks that ventilation does harm rather than good ?—Captain Steinson thinks so undoubtedly.

2616. On the other hand others might think that ventilation would do good ?—Yes.

2617. Being regarded as an uncertain matter even by your own men, you do not interfere ?—Yes, some are for it and some are against it. Captain Steinson has given strong evidence against ventilation from the bottom, he prefers ventilation from the top by opening the hatches and if possible by having other means of access to the cargo from the deck.

2618. (*Chairman.*) Have the rates you have had to pay for insurance risen much lately ?—Yes.

2619. By about how much ?—It differs to various ports.

2620. Can you give us the percentage of increase ?—I cannot give you that, but I know that after the losses of those three ships on their voyages to Aden, and other ships by fire, the rates did go up.

2621. And they have not fallen since ?—I do not think they have fallen since.

2622. So that the company is very much interested in the best information on this subject being obtained as soon as possible ?—Yes ; because though we insure our coals, still we do not get anything like the value of coal when it has been lost ; we merely get the invoice value ; we lose the interest of the money and various other matters, and perhaps we have to pay a higher rate of freight on the cargo sent out in substitution of the lost cargo.

2623. You do not insure the coal at the port of arrival ?—No ; it is only the invoice price of the coal with a per centage added to cover contingencies.

2624. (*Mr. Duncan.*) Have you ever considered whether your casualties were less than those of other parties exporting coals ?—We have never discussed the subject so far as I know. We take all the means we can to get the best ships and to have them examined and so on, but it never struck us to inquire whether our per centage of losses was greater than that of others.

2625. You are not able to say whether your vigilant supervision in the shipment of your coals has produced a smaller per-centage of losses as compared with the losses in the case of other ships carrying coal ?—No.

2626. (*Mr. Ferguson.*) Those three ships the "Oliver Cromwell," the "Euxine," and the "Calcutta" were loaded under Captain Steinsons superintendence ?—Yes.

2627. At the same time that they were loaded was not there another vessel loaded called the "Corah" which was not ventilated and which went safe ?—Yes.

Mr. A. O. Davis.

16 Nov. 1875.

2628. So that the supervision of Captain Steinson being the same over the four ships three were burnt and one not ?—Yes the captain of the "Corah" who was an American, objected to ventilation altogether; he said it was a mistake.

2629. The same description of coal was shipped in the "Corah" as was shipped in the other vessels ?—I believe it was the same coal and the "Corah" arrived at her destination safely.

The witness withdrew.

Adjourned to Tuesday next at 12 o'clock.

Tuesday, 23rd November 1875.

The Right Hon. HUGH C. E. CHILDERS, M.P., in the Chair.

PRESENT:

Frederick Augustus Abel, Esq., F.R.S.
Richard Cory, Esq.
George Duncan, Esq.
John Fenwick, Esq.
John Ferguson, Esq.
Charles Icely, Esq.
William Young, Esq.
J. M. Carmichael, Esq., Secretary.

Captain A. P. Sandeman.

23 Nov. 1875.

Captain Alfred P. Sandeman examined.

2630. (*Chairman.*) You were, I think, for many years connected with the East India navy ?—Yes, in Bengal.

2631. For more than 20 years ?—In active service 23 years.

2632. On shore as well as at sea ?—Entirely afloat during that period.

2633. Afterwards you were surveyor to the London Salvage Association ?—Yes, for two years, during the years 1871 and 1872. I was their surveyor in Liverpool.

2634. As such you had a good deal to do with the ventilation of coal-laden ships ?—I had special instruction to take an interest in the ventilation of coal ships, and to report the particulars.

2635. Subsequently you have been surveyor in the Marine Department of the Board of Trade ?—Since 1873.

2636. In that capacity have you had to turn your attention to the question of ventilation in any way ?—No; the Board of Trade take no action in respect of ventilation.

2637. Your official connexion with that question has been as surveyor to the Salvage Association ?—Yes.

2638. In that capacity you have formed very strong opinions on the subject, I believe ?—Yes, I have had occasion to form a very strong opinion on the subject.

2639. And you wrote a paper on the subject for the Board of Trade, not long ago ?—In the early part of this year.

2640. About the time when this Commission was appointed ?—Yes.

2641. In that paper you have expressed a very strong opinion in favour of a thorough ventilation of coal cargoes ?—Either a thorough ventilation, or no ventilation at all.

2642. But of the two you consider, I believe, that a thorough ventilation is desirable ?—I think it would contribute to overcome the difficulties.

2643. Will you state to us, in general terms, what your views of proper ventilation is, and the reasons you would give for it ?—The ventilation that used to be adopted varied in its character. One plan of ventilation was this. A platform would be built above the skin of the vessel and from the platform there would be vertical shafts at each hatch, and, in cases where there was no permanent 'tween deck fore and aft trunks on or under the lower beams all running into each other. That ventilation, I think, so far as my knowledge goes, has been very effective in keeping the cargo from combustion. There may be isolated exceptions, but I believe, as a rule, all ships that have been ventilated in that way with coal have carried their cargoes to their destination without any spontaneous combustion.

2644. That practice was in force when you went to Liverpool ?—Yes; it had been recommended and encouraged by the underwriters for some time previously, and my instructions were to give it all the encouragement I possibly could. Then a second style of ventilation was merely running an alley-way by means of dunnage wood or boards placed at an angle on the keelson: that gave a fore and aft current along the middle line on each side of the keelson, and into that the vertical hatch shafts were introduced, all the shafts communicating with each other. I do not think that was so good a plan, for it did not give that amount of ventilation under the body of the coal that the platform did, the platform extending, as it did, into the bilges of the vessel.

2645. That was a fixed platform solidly constructed ?—A fixed platform solidly constructed, bearers being laid athwart-ships, and heavy deals laid fore and aft, so that there was a current of air passing from the bilges into the midship body of the vessel.

2646. You consider the second plan of ventilation in which dunnage boards were laid along the line of keels on inferior ?—I consider it inferior inasmuch as it was rarely that the boards were laid with care—they were generally put up and allowed to shift for themselves after they were up; and in many instances to my knowledge they gave way, and the result was that the coal found its way down on to the skin of the ship, and destroyed the current of air, the ventilation being thereby entirely checked and stopped.

2647. Did the failure of that system lead to any further change ?—The next style of ventilation was simply introducing vertical shafts, many shipowners in Liverpool hold that ventilation is of no advantage whatever, and it was only under pressure that they were disposed to adopt it; and in many cases they would merely introduce vertical shafts in the hatches carrying them down as far as the keelson, but there was no current of air kept up by means of those shafts, for they stepped on to the solid body of the coal.

2648. That system failed ?—That system was a failure. My experience is that where the platform system was adopted it was evident that the owner of the ship was interested in ventilating his ship as well as he possibly could, and where the simple vertical shafts were introduced, it was simply that he ventilated his ship under pressure to comply with the wishes of the underwriters having no faith in ventilation himself.

2649. Has the first system which you described as being formerly in force, that is to say, the platform system, been practically abandoned lately for the other system ?—No, it is still adopted in ships sailing from Liverpool and Birkenhead.

2650. Would you advise its general adoption ?—My opinion always has been that ventilation tended to keep the cargo cool, that is if the ventilation was thorough.

2651. You think that imperfect ventilation does not do so ?—Imperfect ventilation would do no good whatever, I should say. Sometimes ventilation is very expensively introduced into a ship, but no interest is taken in that ventilation afterwards to protect it from damage when ships are loading, and particularly where ships load their cargoes under the high level or coal tips, eight or ten tons of coal will be shot out of a waggon into the ship's hold where those vertical shafts are placed and little or no precaution will be taken to protect the coal from falling on the shafts and damaging them, and I have found in many instances that the vertical shafts have got damaged, and have become choked with coal and been rendered simply useless.

2652. Do you consider ventilation necessary because coal is generally put on board damp, or do you insist upon it in the case of coal which has been shipped thoroughly dry?—I should say it would be practically impossible to ship coal thoroughly dry in Liverpool. It is brought from a distance, in waggons and sometimes it is exposed in those waggons for days. It is very rarely that you have a week of dry weather in Liverpool, and my opinion is that the coal is always wet before it is put into the hold of a ship.

2653. In dealing with the question we must assume that the coal is shipped usually in a wet state?—Certainly some portion of a large cargo.

2654. Is it your opinion, as the result of your experience that where coal is shipped dry ventilation is desirable?—I should say under all circumstances it is desirable. There is a very large amount of pyrites in some of the coal shipped from Liverpool, more in some coal than others. There are some coal owners who hold that their coal is non-combustible and that there is nothing in it to cause heating. On one occasion when I was the surveyor for the London underwriters in Liverpool I had to meet Mr. McCulloch, the inspector for the Government of Madras, regarding the cargo of a ship put back from bad weather. The owner was anxious to condemn it, but though we knew there had been seven feet of water in that ship's hold at one time Mr. McCulloch held that there would be no danger in taking that cargo forward. It was a coal shipped from the mines of Pearson and Knowles.

2655. Containing no pyrites?—Very little or none. I may mention an instance where a cargo of that coal did ignite afterwards. That was in the case of the "Palmyra," last year, which carried a cargo of the same coal to Madras. She had merely a vertical shaft in her hold; she had no fore and aft ventilators whatever, and when the latches were opened at Madras, the cargo was found to be in a very heated state and on fire in one part.

2656. You do not attribute combustion solely to moisture in contact with pyrites?—No, the confined air would conduce to combustion also. I have seen some coal shipped in Liverpool which was heavily charged with pyrites. I have seen veins of brass substance three quarters of an inch to an inch thick.

2657. Is it your experience that it is to the pressence of that brassy substance that combustion is solely due?—I should say so.

2658. You think if coal could be carefully picked so as to contain no pyrites you would have no combustion?—I would not like to say that, but I should say there would be much less liability to combustion. I had to do with a cargo of coal on one occasion in India, a cargo of English coal, loaded in Calcutta for the Persian Gulf during the Persian war in 1855 or 1856, and that cargo was hermetically sealed as effectually as any cargo could be on board ship; it was carried in an American ship, and American ships generally are very strongly sealed. The ship put back from stress of weather, having made a great deal of water, and it was my duty to take charge of her as pilot, and I took her to Calcutta. On the passage there we had some very heavy weather, and having occasion to get out some fresh ropes we had to lift the after hatch, and when we lifted the after hatch we found the cargo on fire. The hatches were put on at once, and we tried to get the vessel into a dock to sink her in the dock, but opening the hatches had given vent to the fire below, and at last the smoke came out to such an extent that after consultation it was found necessary to scuttle her. We accordingly cut holes in her side to scuttle her, having put her on shore, but on account of a falling tide were obliged to cut a hole three feet long before we could get the water in to act on the coal, yet no smoke found its way through the hole, showing how closely the vessel was ceiled. The fire was entirely confined to the midship body of the vessel and aft below; there was no presence of fire above. We found that low down the coals had been on fire.

2659. How many days had she been out?—About a month.

2660. It is very unusual for spontaneous combustion to take place so soon after the cargo had been loaded, is it not?—I do not know of any other such case.

2661. (*Mr. Duncan.*) Were those English coals?—Yes.

2662. (*Chairman.*) Re-shipped in India?—Yes.

2663. (*Mr. Young.*) Had they been lying long on shore before they were shipped?—I think not. I think they were shipped from the stores of the Peninsular and Oriental Company as an accommodation to the Government.

2664. (*Mr. Duncan.*) I gather from what you have said in answer to the Chairman's question that you think spontaneous combustion in coals arises from the pyrites that is found in them?—I think it contributes largely to it.

2665. You do not think spontaneous combustion wholly due to the presence of pyrites?—I have not sufficient chemical knowledge to enable me to say definitely that that is so. I know that cargoes of pyrites after being on board only a few days will frequently be landed in a very heated state. I know that in the case of cargoes coming from the Spanish Main where they have only been a few days on board the steamers, when there has been very heavy weather and when the water has got down into the cargo that it became heated, and the stuff of which those cargoes consist is very much of the same character as that which you will find in coal, it being more soft in the coal than in the Spanish pyrites.

2666. I suppose you consider on that account it is more liable to ignite spontaneously?—Certainly.

2667. Have you considered at all what would be the effect of giving an abundant supply of oxygen to pyrites?—The effect would be to prevent its heating.

2668. But if it had got heated what would be the effect?—If it had got heated I should say the effect would be very bad. The supplying of a superabundance of air would prevent its heating I should say.

2669. If it became heated would it be better to supply air?—If I found a cargo on fire I should certainly batten down the hatches, but it is to prevent the possibility of heating that I would recommend ventilation.

2670. Seeing that pyrites even in the course of a few days, if there is any quantity of it on board the ship, gets heated in some way or other whereby it ignites spontaneously, is it not questionable whether in a cargo of coal containing a large proportion of pyrites, and therefore likely to get heated under any circumstances, you could by any system of ventilation make the air so permeate through the cargo that no part of it could get heated?—I think it has been done; very large cargoes of coal have been carried forward in ships which have been thoroughly well ventilated, there are lines of vessels that have had no casualties whatever in carrying their coal cargoes.

2671. Are you aware whether there are any lines of vessels which have never ventilated at all and yet have carried their coal cargoes safely?—Yes, I believe there are lines of vessels in which a system of ventilation has not been adopted, and which have carried their coal cargoes without any accident.

2672. There are a number of such vessels, are there not?—I believe there are.

2673. You have no statistics to give us showing the number of ventilated ships which have carried their cargoes safely in comparison with the number of unventilated ships which have also carried their cargoes safely?—No, I have not, but I have remarked that some vessels that were well ventilated carried their cargoes without any accident, and I have remarked that others which were indifferently ventilated met with accident.

2674. You recommend ventilation for the purpose of preventing the cargo from getting heated, because

Captain A. P. Sandeman.

23 Nov. 1875.

if the cargo got heated, by supplying air you would be providing the elements for spontaneous combustion?—Yes.

2675. Are you aware that it is oxygen that the pyrites requires to cause it to ignite?—If it is excluded entirely from air it will heat, but if air is supplied to it in sufficient quantities I should say it would keep it from heating; confinement causes it to heat and then oxygen causes it to ignite. I would simply recommend ventilation with that view, to prevent its heating. If ventilation will not prevent its heating, then of course ventilation is not desirable.

2676. (*Mr. Ferguson.*) On what ground have you come to the conclusion that ventilation is necessary at all?—From noticing that ships that have been ventilated have carried their cargoes safely.

2677. You are aware that a great number of ships that have not been ventilated have carried their cargoes safely?—I believe that some large ships have gone away without ventilation and have carried their cargoes safely; but I am not aware that a great many have done so.

2678. Is it from statistics or from observation that you come to the conclusion you have with respect to ventilation?—For two years it was my duty to board every coal-laden ship and to report the particulars as to whether she was ventilated or not; it was very rarely that I came across ships that did not ventilate in some way or other, and in many cases I found that the shipowners took a very large amount of interest in ventilation. I do not know that those shipowers who took that large interest in ventilation were careful to prevent the ventilators from being damaged, but I believe they carried their cargoes safely. The conclusion I have formed is that ventilation keeps the cargo from heating and prevents spontaneous combustion.

2679. Could you give the Commission any statistics with respect to those vessels which you supervised for two years, showing the number of vessels that were ventilated and the number that were not ventilated?—I could name some firms that took a large interest in the ventilation of their ships and whose ships were navigated by men who took a great interest in seeing that the ventilation was properly carried out, and I believe that those vessels were in consequence enabled to carry their cargoes without spontaneous combustion.

2680. Have you any statistics to give us showing the number of vessels that carried their cargoes safely that were not ventilated?—I have not.

2681. What you say about ventilation is a sort of general opinion?—It is more the result of my observation whilst I was occupied as surveyor to the Salvage Association.

2682. We have had the cases of four ships mentioned to us which were all loaded at the same port with the same coal, three of them were ventilated, the fourth was not; the one that had no ventilation took her cargo out with safety, while the other three were burnt; would that fact alter your opinion in regard to ventilation?—In the cases of those three that were burnt it is possible that the ventilators may have become damaged.

2683. Your experience is confined to shipments of Liverpool and Birkenhead coal?—Yes.

2684. You have had no experience of shipments on the east coast?—No. What I had to do with was coal from the Midland districts, from Wigan and from Wales.

2685. Are you aware that in a majority of the ventilated vessels that have been burnt, the fire has occurred near the trunk ventilators which have been put in the hatchway?—I am not aware of that.

2686. Was the coal which was shipped at Liverpool and Birkenhead from various pits?—Yes; I had nothing to do with the shipping of the coal, I had merely to report to the underwriters that such and such coal was being put on board.

2687. You did not investigate the quality of the coal?—No, not beyond looking at it in the waggons.

2688. You only made a superficial observation of it?—That was all.

2689. Did you observe that the vessels took fire which carried coal with a large amount of pyrites in it?—I cannot say that I did.

2690. (*Mr. Duncan.*) What is the result of your observations with regard to the quantity of pyrites contained in coal shipped on the Liverpool side of the Mersey as compared with that shipped on the Birkenhead side?—The coal shipped on the Liverpool side has less pyrites in it.

2691. (*Mr. Abel.*) From your evidence I gather your view of the effect of proper ventilation to be this, that by passing sufficiently rapidly and in sufficient quantity cold air over the heated coal you prevent an accumulation of heat, and you even remove the heat which has been generated?—That is my view.

2692. Do you think it is possible to stow coal on board ship with such care and with such arrangements for natural ventilation as to ensure the passage of air thoroughly through anything like every portion of the mass of coal on board ship?—Not through every portion, but you could carry these trunk ways through various sections so as to ventilate a larger cubical space. At present you have merely two fore and aft ventilators on the middle line below, and probably one or two in the middle body of the vessel, but I would increase those fore and aft ventilators, and so operate on a larger space.

2693. With the very best possible arrangement of natural ventilation, would it not be the case that you would still only ventilate portions of the cargo?—No doubt, but you would reduce the amount of solid coal unventilated. As things stand now there is a very large body of coal that has no ventilation whatever, and the suggestion I make is with a view to carry ventilation through that mass of coal.

2694. Do you think any arrangement of shafting could ensure the carrying of air through the main body of the coal?—I do not see why it should not in the same way as it is carried through a body of rice.

2695. Under any circumstances the ventilation would only be partial ventilation, would it not?—If you arranged the ventilators so as to operate at intervals of 9 or 10 feet I should say, as all the coal does not lie quite solid, that it would tend to reduce the liability to heat.

2696. (*Mr. Young.*) I have a paper before me signed by you dated March 3rd, 1875, at the beginning of which you say, alluding to vessels burnt at sea, "We may with truth say a week now seldom "passes without its sad tale of loss in many "instances of life, as well as of valuable ships, "and all attributable to this cause," and in another place you say, "The sooner it is insisted upon" (that is to say ventilation) "and made compulsory, "the sooner will we hear of the sad and revolting "catastrophes which have lately resulted from spon-"taneous combustion with coal cargoes on foreign "voyages." Are you aware of the number of vessels that have been lost from spontaneous combustion of coal as compared with the number that have gone with safety in 1874?—No. I do not know that there was a large proportion lost, but the losses were very serious.

2697. Should you be surprised to learn that the proportion of losses was about 1 in 2,000?—I am surprised to hear it.

2698. Do you know how many lives were lost in those "revolting catastrophes" that you allude to?—I was alluding then particularly to the loss of the "Euxine" and one or two other vessels; the cases were very revolting, I thought.

2699. Do you know how many lives were lost?—There was a large loss of life.

2700. Should you be surprised to learn that there were only 27 lives lost altogether in 1874?—I should have thought the number of lives lost would have been greater, but you have the data; I have none.

2701. In your paper you appear to point to a compulsory inspection by the Board of Trade, or by the Government, of all ships loading with coals. Do you still adhere to the opinion that such an inspection

Captain A. P. Sandeman.

23 Nov. 1875.

would be advisable?—If ventilation is necessary, it ought to be carried out effectively. Many ships are ventilated and the ventilation is of no use whatever.

2702. Do you think Government interference would would make it effective?—It would contribute to it.

2703. You think ventilation of coal-laden ships could be effectively carried out only by a Government inspection of every such ship?—I do not say that. In my paper I merely said that so far as I knew, the ventilation that was adopted in coal laden ships was often seriously damaged from want of care and want of interest in it.

2704. You recommend that all coal-laden ships should be inspected?—I confess that was my view, but what I recommended in my paper about supervision applied specially to boats.

2705. Have you considered the question how it would be possible for the Government to inspect every coal-laden ship?—I know many instances where, if I had been a Government inspector, I could have been instrumental in keeping the ventilators from being damaged which were damaged and not put to rights.

2706. Do not you think the owner, the captain, and the crew would naturally take care of those things?—There may be no captain with the ship.

2707. Then there would be the mate?—Frequently the mate does not take interest in such matters.

2708. Do you think the supervision of a Government surveyor better than the care which men directly interested in the matter may be supposed to take?—I think it just possible that a Government surveyor's inspection would be better. He might see that it was done.

2709. Are you aware that in 1874 there was shipped from England 12,000,000 tons of coal?—No doubt you are correct.

2710. How many thousand inspectors would that require?—Not many. It does not take a man long to see that the work is being done properly; if he had to direct it himself it would take a very large number.

2711. If the object was to prevent the ventilators being damaged an inspector would have to be always present when a ship was loading?—Under those circumstances it would take a very large staff, but I never intended to suggest any such measure.

2712. (*Chairman.*) Coming to the last point first, there are two ways in which the law might interfere; it might simply require a certain system of ventilation to be applied to all coal-carrying ships, or it might in addition to that requirement direct that inspectors should be appointed to see that it was carried out. Is it your advice to us to recommend that a law should be passed enforcing a certain system of ventilation?—Yes, if it is considered that ventilation is desirable. If my opinion is not justified, of course such a law should not be passed, but if ventilation is desirable it ought to be carried out effectively. Certainly some interest should be taken in ventilation, and my experience is that no interest as a rule is taken in the ventilation of ships, though there are exceptions; there are many owners who take a very large interest in the ventilation of their ships, and there are others who take no interest in it whatever, though ventilators are put into their ships.

2713. You would recommend us to advise Parliament to pass a law enforcing a certain system of ventilation?—Yes, being of opinion that ventilation is desirable.

2714. Would you in addition to that, as an administrative arrangement, not only require that ventilation, but appoint officers to see that the requirement was enforced?—My feeling is that it would be necessary that some one should be present at the loading of the ships to see that the requirement was carried out.

2715. You would not leave it to the ordinary process of law to punish the owner who did not comply with it, but, as I understand, you would require that inspectors should be appointed to see that the law was properly carried out?—I cannot say that I am able to offer a decided opinion upon that point. I should suppose that inspectors would be appointed.

2716. You have not considered the administrative point sufficiently to be able to give us any distinct recommendation in regard to it?—No; I quite feel that there is very little interest manifested in ventilation, and if ventilation is of any advantage whatever possibly it might be necessary that inspectors should be appointed.

2717. You said in reply to Mr. Young that the strong language you used in your paper was induced by the loss of the "Euxine" and one or two other ships about that time. There were three ships lost about that time, viz., the "Euxine," the "Oliver Cromwell," and the "Calcutta." Are those the three you refer to?—Very likely. The "Euxine" I know was one.

2718. They were loaded in the same month and were lost about the same time?—Yes.

2719. Are you aware that those three are the very ships to which Mr. Ferguson referred when he said that out of four ships which sailed on the same voyage, for the same company, with the same coal, three of them being ventilated and one not, the three that were ventilated were lost, while the one that was not ventilated (a vessel called the "Corah") reached her destination safely?—To my knowledge on one voyage the "Euxine" had her ventilators damaged. Referring to my reports I find I reported that the after ventilation was choked with coal. I think she is a ship that generally loads under the tip in the West Float, and it is a questionable thing whether the vertical shafts of the ships are not in many cases damaged in loading under these tips.

2720. Would not it shake your impression, which was strengthened at the beginning of the year by those three casualties happening just together, to learn that those three were distinctly cases of ventilated ships, those cases having been brought before us pointedly by witnesses as evidences of the impolicy of ventilation, seeing that those vessels were lost while another ship, loaded with coal in the same dock (the Northumberland dock in Newcastle) at the same time and for the same owners (the P. and O. Company), arrived quite safely though not ventilated?—That is a very strong case certainly.

2721. With regard to the cost of ventilation. You have compared the ventilation of rice cargoes with the ventilation of coal cargoes. I suppose the freight of rice is a very much better freight than the freight of coal?—Yes.

2722. So it does not at all follow because a particular system of ventilation could be applied to rice that it could be applied to coal?—An increased freight would have to be charged if an improved system of ventilation were adopted.

2723. What would it cost to thoroughly ventilate on your plan a cargo of 1,000 tons of coal?—I do not think it would cost a great deal. The ventilators are made of rough deals, and rough deals are to be had very cheap. I give you an idea of the expense in my paper, viz., 1*s.* 6*d.* a ton.

2724. 1*s.* 6*d.* a ton is a very serious per-centage, is not it?—It is very trifling when weighed against the additional premium that is frequently charged.

2725. Which has been charged within the last year or two?—Yes.

2726. Have you observed that the premium is apparently out of all proportion to the risk, looking at the per-centages before us?—Yes; the per-centage of loss appears to be very small.

2727. The 1*s.* 6*d.* is a very serious addition to the other charges, is it not?—Yes; it would be an additional expense, no doubt.

2728. When you estimate 1*s.* 6*d.* you take it as the minimum; it might be considerably more?—No, I do not think it would be more.

2729. (*Mr. Fenwick.*) You say some shipowners are very particular with regard to ventilation, and some take no interest in ventilation whatever?—Yes.

2730. To what do you attribute that?—To want of confidence in ventilation, I suppose.

The witness withdrew.

Mr. M. Anderson.

23 Nov. 1875.

MR. MATTHEW ANDERSON examined.

2731. (*Chairman.*) You are a shipowner at Leith?—Yes.

2732. And you have been for some time, we understand, superintending engineer there?—Yes, for the last 12 years.

2733. In that capacity what have been your duties?—I have had to do with the loading of ships and looking after the engines, boilers, the coal, and so on.

2734. The subject of coal has come especially under your attention?—Yes; I was born close to a coal pit.

2735. Have you had any experience in the loading of coal ships?—I have not had to do with any ships taking entire cargoes of coal; but I have seen scores of ships loaded with entire cargoes of coal.

2736. You have not had the superintendence of the loading of those ships?—No; I have merely seen them.

2737. You have had the superintendence of the loading of coal in ships' bunkers?—Yes.

2738. You have arrived at some conclusions on the subject of the proper ventilation of coal?—Yes.

2739. Will you tell the Commission what those conclusions are?—I think that spontaneous combustion always arises from the presence of pyrites—what we call "brasses"—and when the water comes in contact with it it dissolves the sulphur of the pyrites and heat is evolved, and hence the coal ignites after a certain time. I know that from experience. In the district in which my father was a colliery engineer, formerly, when there was no demand for waste coal it was all put into great heaps, and after a certain time the rain or the snow came on to it, and spontaneous combustion took place. I could see from where I lived no less than 20 or 40 of those heaps on fire by spontaneous combustion. My opinion therefore is that when coals, if they contain pyrites (and very few coals are free from it), are put into a ship's hold, as soon as water is brought in contact with them spontaneous combustion takes place.

2740. What is the remedy you would apply to prevent it?—You cannot prevent it, do what you like, only if you could put the coals in perfectly dry and keep them dry there would be no fear of spontaneous combustion.

2741. It is your impression, that whether ventilated or not, coal will take fire at a certain time, if it is wet?—Yes, decidedly so. Ventilation, in my opinion, is only useful when coals give off a lot of gas.

2742. To prevent explosion?—Yes.

2743. But it has no effect in preventing spontaneous combustion?—No. For instance, there was a colliery in the West of Scotland, that was a fire for months and they had no means of putting it out, but a Dr. Gurney took it in hand and he excluded all the atmospheric air, where he could and pumped carbonic acid into it for weeks, and eventually put it out. My idea of the best way of preserving coals from spontaneous combustion is to put perforated pipes down each side, to divide the ship into two halves, each side of the keelson, and to have perforated pipes leading down from the deck. Then I would take a daily record of the heat by lowering a thermometer so as to see whether the heat rose or not. If the heat rose, you might be sure that the first stage of spontaneous combustion had commenced; if it went on increasing, I would exclude the atmospheric air, if it still went on increasing, then carbonic acid gas would be the best thing to put it out, because carbonic acid expels all the atmospheric air. If the atmospheric air were entirely excluded, there would be no oxygen to feed the coals, and hence the fire would so go out.

2744. Then so far as prevention is concerned, you do not think that either ventilation or the absence of ventilation makes any difference?—No.

2745. You think that coal of a certain description, with a certain amount of pyrites in it, and with a certain degree of dampness will take fire whatever yon do?—Yes.

2746. And that all we have to look to is to prevent that kind of coal from being put on board in that state, and to provide the best way of putting the fire out when it came?—Yes, that is my opinion, to discover the first stages of it, and check it in its first stages

2747. But you think that no artificial contrivance in the character of ventilation will do any good?—Not when a large body of coals is put on board ship in a damp state.

2748. Your belief is that coals never take fire except they are put on board in a damp state?—No. As a proof of that, I remember the colliery where my father was engineer for, the small coal which was thrown aside and exposed to the wet took fire, but the other coal, which was protected from the weather did not take fire. At times there was not a sufficient demand for the coals to keep the collieries employed, and they used to bring the best coals to the surface, and, to protect them, they used to be put in sheds where they could be kept dry.

2749. And you never knew a case of dry coal taking fire spontaneously?—No.

2750. Your opinion is, that the presence of pyrites, and the presence of moisture are the sole causes of spontaneous combustion?—Yes.

2751. And you are of opinion that under those conditions spontaneous combustion infallibly follows, whatever precautions you take?—Yes.

2752. (*Mr. Duncan.*) Then you disapprove of the idea of ventilating ships by shafts through the hatchways?—To prevent spontaneous combustion, certainly.

2753. You would allow the gases that escape from the coals to get out?—I would make provision for that.

2754. Your opinion clearly is that it is not judicious to put ventilators through the coals?—Except to ascertain the temperature, which I would do by means of those pipes.

2755. Are you of opinion that ventilation might do harm?—If the coals are put in damp, and therefore liable to spontaneous combustion, it does do harm, inasmuch as atmospheric air is one of the elements that is required to dissolve the sulphur; and therefore the more air you introduce, the worse it becomes; the more atmospheric air you add, and the more hot it becomes, so as to give off flame or heat the worse it becomes.

2756. Irrespective of that, in the first stages of spontaneous combustion, is there any element in atmospheric air which would have a tendency to combine with pyrites, and so produce combustion?—The atmospheric air and the water dissolve the pyrites and liberate the sulphur, and then the action takes place upon the coals. That is the first stage of it.

2757. For the purposes of igniting the sulphur, you do not think a gas is required to be combined with it?—No; the gas is the product of the decomposition of the iron pyrites in the coal.

2758. There would be gas evolved if water was decomposed and put into a gaseous state?—Yes. Where do you derive the gas from, if it is not from the decomposition of the coal?

2759. You do not think that thorough ventilation throughout the bulk of the coals would be a matter that this Commission should recommend to be introduced in every ship?—If I had a ship loaded with coals, the plan which I have suggested is the plan I would adopt: that is the only one I recommend.

2760. That is to put perforated tubes down and ascertain whether the temperature was rising or not, and if you found that the coals were on fire, you would force down carbonic acid in order to put the fire out?—Yes. If carbonic acid was not available, those pipes would convey water down below.

2761. Those pipes would only convey a limited quantity of water down, would they not?—If you had a 4-inch pipe that would convey an unlimited quantity.

2762. You would flood the ship with water?—Yes, and that would put it out. If those pipes were like telescopic tubes it would be a very simple process to put them in.

Mr. M. Anderson.

23 Nov. 1875.

2763. (*Mr. Ferguson.*) We have had it in evidence that coals carried in iron ships, which were loaded in perfectly dry weather, took fire; how would you account for that?—I would not believe it.

2764. Is it a fact that some coals contain water in themselves?—No; coals contain no water, but coals will absorb water.

2765. Supposing they have not been exposed to any surface water, is not it the fact that there is a certain per-centage of water in some kinds of coal, and more in some kinds than others?—No.

2766. It has been attempted to account for the fact of coals shipped dry taking fire by the theory that they contained a certain quantity of damp in themselves, and that that, along with the pyrites, caused spontaneous combustion?—There are certain elements which go to form coal, I cannot tell you the constituent parts of coal, but I never heard of water being one of them.

2767. I think some of your Fife coal contains a great deal of water?—Simply for this reason, in the Fife coal field there is water adjoining the pits; there is water constantly in the pits, both at the top and the bottom of the seam, but that is an absorption of the water into the coal.

2768. You think that the coal that is said to have been shipped dry may have contained water in it which it had absorbed?—Yes; it very likely may have contained water that it absorbed, but of the elements that go to make up coal, water is not one.

2769. If there was water in the ship's hold and the coal contained iron pyrites, you probably think that that would account for the coal that was shipped in dry weather taking fire?—The water which the coals had absorbed previous to their being put into the ship, and the pressure of iron pyrites, would conduce to generate heat.

2770. Are you familiar with the Scotch coal shipped at Glasgow and Leith?—Yes; I know the Bonnie Hill, the Rough Rigg, the Stan Rigg, and some of those other Wishaw coals.

2771. Are they all equally liable to spontaneous combustion; is the pyrites contained in the coal wrought from all those pits about the same?—In the Rough Rigg and the Stan Rigg it is the same. I cannot go through the whole catalogue of the various descriptions of coal.

2772. Your idea is that pumping in carbonic acid is the proper way of putting out fire which has taken place in coals from spontaneous combustion?—That is the quickest method of stopping the fire.

2773. Do you consider it better than pumping in water?—In the first instance, certainly, because you do not injure the coals to the extent that you do by pumping in water.

2774. Would the carbonic acid injure any other cargoes?—Certainly not; the carbonic acid being heavier than atmospheric air, it has a natural tendency to descend and expel the atmospheric air.

2775. Supposing it was put in at the bottom of the vessel, at the keelson, would it rise and expel the air?—No.

2776. It would lie at the bottom of the ship?—Yes.

2777. (*Mr. Young.*) Where were those heaps of coal which you say you have seen on fire?—In the county of Durham, at the Marquis of Londonderry's collieries.

2778. Were those coals stacked for the purpose of preservation?—No; at that time, 40 years ago, there was no demand for coke, for railway or for other purposes; iron smelting was in its early stage, and the coal was all screened. That was the small dust put away as being useless. They used to make the tracks for the railways with those small coals.

2779. Practically nobody cared whether they were burnt or not?—No, they took no interest in them whatever; they did not take the trouble to set fire to them.

2780. (*Mr. Icely.*) You said that your experience with regard to the stowage of coal was confined to ships' bunkers?—Yes, and what I had seen shipped on the Tyne.

2781. Have you any experience of spontaneous combustion taking place in coal taken into a steamer's bunkers?—Yes, I had one case of a fire.

2782. Could you give the Commission any information with respect to that case?—In that case the fire arose from the coals being put into the bunkers damp, and the bunkers being a little too near the boilers.

2783. You think possibly the communication of heat from the boilers had something to do with it?—The coals had only been in the bunkers a few days when they took fire; the heat was the originator of the combustion.

2784. The heat being communicated by the boilers?—Yes.

2785. At what distance were those bunkers from the boilers?—12 inches.

2786. Do you think it was possible that the heat could be communicated. The boilers would have some non-conducting substance on the outside of them; do you think it would pass through that non-conductor and then through a space of 12 inches and affect the coals?—It did so; and as a means of prevention I put another plate a couple of inches apart from the boilers, so that there might be a current of air between.

2787. It was your impression that the heat was communicated to the coal by the boilers?—Yes; we never had the same casualty again, though we used the same coals afterwards.

2788. Can you tell the Commission whether those coal boxes were ventilated or not?—They were ventilated in the usual way, by taking the lid off when the men went down.

2789. It was simply an exit for the gases that might have accumulated?—It had always been found sufficient.

2790. You say the coals were only a very short time on board?—Yes; they got wet coming off in the craft that brought them to the ship; they caught fire after being out 11 days.

2791. Was it the custom to take the temperature?—No.

2792. How was the fire discovered?—By the trimmers going in to trim the coals. The coals had not got on fire to such an extent as to set the ship on fire, but they were smouldering and hot and ready to burst into a flame.

2793. You were convinced that the fire had arisen from the moisture of the coal?—The coals had gone in damp, and coming on board wet, together with the heat from the boilers, combustion was generated a great deal sooner than it would have been if the coals had been put in dry and there had been no heat near.

2794. That is your only experience of any casualty in the case of coal stowed in bunkers?—Yes.

2795. (*Chairman.*) The pipes which you would pass down in order to take the temperature would admit of air going down too?—Yes.

2796. Would you put taps on them?—Yes; I would screw taps on them, I would make use of them either to put the thermometer down or to put down carbonic acid, or water if carbonic acid was not available.

The witness withdrew.

Mr. William Darley examined.

Mr. W. Darley.

2797. (*Chairman.*) You were formerly foreman of the yard at Chatham?—Yes.

2798. And lately you have been employed as a Nautical Assessor under the Board of Trade?—Yes.

2799. In that capacity you have had some experience of cases of explosion or spontaneous combustion in coal ships?—Yes, such cases have come under my notice in the inquiries on which I have sat.

2800. How many such cases have you been concerned with?—The "Zeno" was one.

Mr. W. Darley.

23 Nov. 1875.

2801. Was that a case of explosion or spontaneous combustion ?—Explosion of gas. Then there was also the case of the "Berwick."

2802. Was that a case of explosion or spontaneous combustion ?—That was a case of explosion. Then there was the "Maria Lee." I think that was not an explosion from coal, but ignition from spirits. Then there was the "Herbert Graham," that was a case of spontaneous combustion.

2803. So that in those inquiries two cases of explosion, and one of spontaneous combustion have come under your notice ?—Yes.

2804. Have you any other experience of spontaneous combustion on board ship ?—When I was foreman afloat at Sheerness, and had charge of the ships in the harbour there, I found there were cases of spontaneous combustion on board ships in which the coal was stored. Those were cases of extreme heating of the coal, and there was one case occurred in the dockyard, where the coal took fire.

2805. To begin with the causes, what is your impression with regard to the cause of spontaneous combustion of coal ?—I believe spontaneous combustion of coal to arise from various causes ; one cause is the shipment of "green" coal. I do not consider it safe to ship very green coal.

2806. What do you mean by "green" coal ?—Coal taken from the pit's mouth and transferred directly to the ship.

2807. (*Mr. Duncan.*) Would you call it fresh wrought coal ?—Yes, fresh wrought coal taken from the pit, and put at once on board ship. In the next place it is not safe to ship coal in rainy weather. If you ship coal in rainy weather it is more liable to ignite spontaneously.

2808. (*Chairman.*) With regard to "green" coal you consider that shipping the coal in a "green" state is a cause of danger whether shipped in a damp state or not ?—Yes.

2809. Danger in the sense of spontaneous combustion or of generation of gas leading to explosion ?—Both.

2810. Have you had any experience of spontaneous combustion in dry coal ?—No ; in the case I referred to which occurred in the dockyard the coal was shipped in very wet weather.

2811. So far as spontaneous combustion goes your experience is only of coal which has absorbed moisture ?—Coal which has been exposed to moisture.

2812. As to "green" coal, how does that produce spontaneous combustion ?—When it is wrought from the pit it is full of gas ; if it is exposed to the atmosphere previously to being shipped some of that gas is emitted that would be otherwise retained, but when confined it becomes dangerous and ultimately heats.

2813. Does the presence of that gas in dry coal lead to heating or only to explosion ?—I judge that the "green" coal is never very dry. I think there is a certain amount of humidity in it.

2814. So that in the long run it comes to moisture being the cause of spontaneous combustion ?—Yes. The tendency of wet is to cause a decomposition of the coal I believe.

2815. It comes therefore to this, that the cause of spontaneous combustion in your opinion is moisture, however that moisture may be generated ?—Yes. In the case to which I referred as having occurred at Sheerness I had a correspondence with Mr. Rogers who had charge of the coal depôt there. I wanted to satisfy my mind upon it, and he told me that the coal was shipped in wet weather, and in each case where I have come across coals that have been destroyed by fire I have found on inquiry that wet has had something to do with it.

2816. That being so, I suppose your opinion is that the first precaution which should be taken is not to ship wet coal ?—Not to ship wet coal.

2817. That would be the best of all remedies ?—Yes.

2818. What is the next preventive measure you would take —In the next place I would put it into a dry ship.

2819. Assuming coal to be shipped which was not perfectly free from moisture, what appliance would you use in order to prevent spontaneous combustion ?—You want to keep it dry. There are some coals that do not require so much ventilation as others ; it depends on the quality of the coal. In some it is necessary, I believe, that you should have no ventilation at all (or at least only surface ventilation), or the tendency would be to cause spontaneous combustion. As far as my experience goes I would not offer an opinion whether earthenware tubes introduced into coal liable to spontaneous combustion would not produce a beneficial effect in the earlier stages, because when the gases are compressed and confined the tendency, I believe, is to heat the coal, and then danger arises ; but perhaps if the gases were allowed to escape from perforated pipes that might be prevented ; but that is a matter of speculation.

2820. You are not able to give us any distinct opinion of your own upon the question whether ventilation does or does not obviate the danger of spontaneous combustion ?—No, I have never heard of ventilation generally injuring coal. I have found in the generality of cases where coal has sustained injury that it has been in the absence of ventilation.

2821. In the case of the "Herbert Graham," was the ship well ventilated ?—I do not think she was properly ventilated, and I am doubtful whether she was a very dry ship. I cannot remember positively whether the coals were shipped wet in the "Herbert Graham." If they were shipped wet it would account for the spontaneous combustion.

2822. You do not remember whether there were any appliances for ventilation in that ship ?—From my inquiries I was not perfectly satisfied with the ventilation.

2823. What is your recommendation as a whole upon the subject of ventilation. I gather that in the case of some coal you would not ventilate it at all ?—In the case of some coal you need to be very cautious in ventilating it. The fact is on that point I am hardly competent to give a decided opinion ; there are some cases that are a little doubtful, and they want experiment.

2824. This Commission being appointed specially to report upon that question, you do not feel able to give us any very distinct recommendation upon the subject of ventilation ?—I think that surface ventilation cannot do any harm. I think it would be well to test, by experiment, the effect of the introduction of earthenware tubes into cargoes of coal known to be liable to spontaneous combustion. It might probably be found that the introduction of such tubes would have a beneficial effect ; that is to say "before" heat has been generated. I believe, as others have observed, that the effect of introducing atmospheric air afterwards would be only to increase the combustion.

2825. Do I rightly gather that you would recommend that experiments should be made to test these matters ?—Yes.

2826. So far as explosion is concerned you are of opinion that every facility should be given for carrying gas off ?—Yes.

2827. Would you do more than that ?—Yes ; I would insist that the coals, after being taken from the pit, should be exposed a certain time to the atmosphere in order to allow for the escape of the gas.

2828. After they were on board all you would do would be to ventilate the surface ?—After they were on board they should be kept dry and be properly ventilated. I know of no better system of ventilation than that introduced in the Royal Navy, and which I explained to the court at Hull in the case of the "Zeno." There are some matters of detail which I could add to it, and particular modifications might be applied to particular sorts of vessels. The system to which I refer is a system of pipes and cowls—a system which has been introduced into the Royal Navy with the greatest possible success. Some men would object to going to the expense of large iron tubes, and in some cases copper tubes, where they come near the binnacle, but

Mr. W. Darley.

23 Nov. 1875.

wooden trunks might be used with advantage, and in some cases wind sails.

2829. That is for surface ventilation ?—Yes; and I would recommend that you should carry it into the body of the coal also. Take the case of Cardiff hard brittle coal, you may ventilate it to any extent. I believe the principal danger that you find in coal of that description is that when a naked light is brought into proximity to it an explosion takes place. In each case of explosion that I have come across in that coal the explosion has taken place in consequence of a man taking a light below. Then I think the system of fitting up a ship should be such as to prevent the gases accumulating, so as to prevent parts of the ship where coal is not stowed acting as receptacles for gases.

2830. I think M. Vassard, whom you examined in the "Herbert Graham" case, in answer to a question put by you, said that in the case of coal containing pyrites there should be no ventilation, as it was liable to ignite spontaneously, and that ventilation was only useful in the case of coal containing no pyrites, in which case it was of use for carrying off the gas and to prevent explosion. Is that your view ? — I should defer to the opinion of M. Vassard on that question; he is a chemist and more competent to give an opinion on such a point than I am.

2831. Do you agree with M. Vassard ?—Yes. In addition to a system of ventilation for the coal, it is necessary that precautions should be taken for the ventilation of the ship. This is a drawing of the "Zeno" (*producing it*). This (*pointing to the compartment the fore side of the coal hold*) became a receptacle for the gas generated from this coal. The bulkhead not being watertight or not being airtight, the gases that were generated here passed through, and the result was that this was made a receptacle for the gas. This (*pointing to it*) was used as a water ballast tank, and there was a pipe leading from here into the hold to let the water off, and I believe there were a couple of holes in the deck, to allow the gases to escape and to run off any water that might be here into the ballast tank. That answered two purposes; whilst it allowed any wash of water to run down it also allowed the air to arise; consequently this (*pointing to the compartment the fore side of the coal hold*) always became a receptacle for gas. When one of the men went down through the forepeak with his light the gas exploded, blowing him into the bows of the vessel, and in 50 minutes there was 33,000*l.* worth of property gone, and 29 hands had to take to an open boat in the Bay of Biscay.

2832. (*Mr. Duncan.*) You say that there is greater danger of spontaneous combustion if the coals are shipped wet. Have you formed any definite opinion as to the effect of water upon the coals in producing spontaneous combustion ?—A chemical action goes on, I believe, on the introduction of water into the coals, tending towards spontaneous combustion; and there is a demonstration of that in the circumstance that in those cases where spontaneous combustion has taken place the coal has been brought in contact with the wet either by being shipped wet or by being put in a wet ship.

2833. Supposing you were told that in numerous cases where the coals had been shipped as dry as possible those coals had taken fire, and in addition to that, as appears from the statistics which have been taken, it turns out that the coals in which the greatest number of cases of spontaneous combustion took place were coals shipped in the three driest months of the year, would that have any effect upon your judgment ? —It would lead me to hesitate in giving a definite opinion with regard to wet; but of course there are different descriptions of coal, and what would affect one would not affect the other.

2834. Did I rightly understand you to say that water does not affect Cardiff coals ?—I believe that water does affect them, that is that they are better kept dry, but I have come across no cases of spontaneous combustion in Cardiff coals that have been wet.

2835. Has it ever occurred to you to inquire whether the component elements of Cardiff coals, and of those other coals that have taken fire frequently are different from one another ?—Yes, I believe they are different from one another as shown by the different effects produced, because one will explode and the other will ignite. The coal from Cardiff, particularly the Cardiff hard brittle will explode. I do not know (because I have not got extensively into it) whether you will find that it is liable to ignite spontaneously, but in some correspondence which I have had with people at Cardiff and which is contained in a paper which I beg to hand in (*handing in the same*), they tell me that they have come across no cases of spontaneous combustion in that coal.

2836. Do they say what spontaneous combustion arises from ?—Yes, the presence of a large quantity of iron and sulphur in the coal which, when acted on by water, produce a chemical action, causing spontaneous combustion.

2837. It is clear that there are two elements of danger in coals. Is your recommendation to the Commission that different courses of action should be taken with coals that have those different dangers in them ?—Yes, decidedly.

2838. That is to say that those Cardiff coals that are liable to explode should be differently dealt with from those that have large quantities of pyrites in them ?—Yes, just so. My experience has been more particularly in cases of explosion. I have only sat as nautical assessor on one case of spontaneous combustion, that of the "Herbert Graham." Then there was the case that occurred at Sheerness where the coal took fire, in that case the coal had been exposed to wet.

2839. In the case of the "Herbert Graham," was the quality of the coal shipped on board a subject of inquiry ?—Yes. Mr. Vassard was present and gave his report. I think you will find the report in the evidence.

2840. Do you remember whether the coals that that vessel had on board were more dangerous than the coals ordinarily shipped ?—I cannot charge my memory with that.

2841. You are not prepared to speak definitely as to what precaution should be taken in the case of ships having on board these coals which are highly charged with pyrites and liable to spontaneous combustion ?—No; I would not give a positive opinion upon that. I would suggest that a great deal might be gleaned by the Commission from those who are constantly shipping the coal. No doubt also coal owners at different ports for their own interest would be glad to give you information upon the point.

2842. (*Mr. Ferguson.*) You say that some coal requires ventilation, will you tell the Commission on what grounds you come to that conclusion ?—From the terrible explosions that have taken place where ventilation has not been attended to.

2843. That is in reference to Cardiff coal that explodes, not coal that is liable to spontaneous combustion ?—Just so.

2844. Is that system of ventilation by which the gas is taken from the top of the coals to the deck by pipes and cowls the system which you say has been adopted in the Navy with success ?—Yes.

2845. In the coal-carrying vessels of the Navy have there been fewer explosions than in other vessels carrying coals ?—I believe you will find that to be the case.

2846. Has the system to which you refer been adopted in the vessels of the Navy as well as in vessels carrying coals for the Navy, and does the answer you give with respect to comparative immunity from accident apply to both classes of vessels ?—Yes.

2847. Do they keep some vessels of their own to carry coals in ?—I believe in some cases they do. At all events they have vessels in which their coals are stored as coal depôts, where they remain for a considerable time.

2848. Your experience has been more in the explosive coal ?—Yes.

Mr. W. Darley.

23 Nov. 1875.

2849. You cannot say whether ventilation is good or whether it is bad in the other kind of coal?—I cannot say positively.

2850. (*Mr. Abel.*) Your experience with regard to explosions on board coal-laden vessels is limited to two instances?—Yes; it is limited to two instances.

2851. You have no idea what proportion of casualties is ascribable to explosions on board coal-laden ships, and whether it is large or small?—I believe there is a great number of coal-carrying ships in which explosions take place, many that you hear nothing of. When we were sitting at Hull on the "Zeno," a vessel exploded, I could not tell you her name, and there was a loss of life. There was one case I read about in which 22 men out of 23 were blown into the air. Another where 8 were blown into the air, 4 fell overboard and were drowned, and 4 fell dead upon deck. Such cases are of common occurrence. I have not the slightest doubt that a great many cases have occurred, in which vessels have been lost from explosion, and all hands sacrificed. In this case of the "Zeno," 29 people had to put to sea in an open boat, and if there had been the usual weather in the bay, they would have been all lost, no doubt. The evidence that that vessel was not properly fitted was very clear, and in fact, it was admitted by the owner of the vessel, for when I was in the court I expressed an opinion that the vessel was built for one purpose and used for another, and the representative of the owner rose and admitted that that was the fact, that she was built for a general cargo, and in that exceptional case she was used for a coal cargo, that coal being a dangerous coal.

2852. (*Mr. Icely.*) With regard to the casualty which occurred at Sheerness, that was in a hulk?—Yes.

2853. Did any case of spontaneous combustion or explosion ever come under your notice in the case of any ship afloat having coal on board?—I have never known any such case in any vessel belonging to the navy.

2854. Are you aware whether it is the custom to keep coal in navy ships in harbour for any length of time?—No.

2855. Is not there a First Division of Steam Reserve, consisting of vessels having coals and other stores always on board?—There is a certain quantity of coals on board such vessels, but I do not think the bunkers are all filled up.

2856. Those ships are supposed to be ready for sea, and they have all their stores on board, coal included?—I am not able to speak confidently on that point.

2857. Are you aware that some of those ships will remain probably a year or two without being employed the coal still remaining on board?—I have not known any vessels remain in the First Division, at Sheerness, so long as that.

2858. Not for a twelvemonth?—No, I do not think so.

2859. For six months?—I should think they have perhaps for six months.

2860. During that time you never heard of any accident occurring?—No, I have heard of cases of the coals becoming heated and in those cases the engineers, who are very careful men, watch the coals; they daily test the heat of the coals by the thermometer tubes, and if they have any doubt of their safety they have them removed either to another bunker, or on deck.

2861. You attribute the immunity from accident in those ships to those precautions being taken by the engineers?—Yes, and the system of ventilation that is generally adopted.

The witness withdrew.

Adjourned.

Tuesday, 15th February 1876.

PRESENT:

GEORGE DUNCAN, Esq., IN THE CHAIR.

FREDERICK AUGUSTUS ABEL, Esq., F.R.S.
RICHARD CORY, Esq.
JOHN FENWICK, Esq.
CHARLES ICELY, Esq.
WILLIAM YOUNG, Esq.
J. M. CARMICHAEL, Esq., Secretary.

MR. WILLIAM JACOB PRIM examined.

Mr. W. J. Prim.

15 Feb. 1876.

2862. (*Chairman.*) You are resident engineer to the Houses of Parliament?—Yes.

2863. And you were formerly chief assistant to the Manchester Steam Users Association?—Yes.

2864. How many years were you there?—About eight years.

2865. And that was about the year 1865?—Yes.

2866. Was that when you left the Association?—No, I left in 1868. I have been at the Houses of Parliament since 1868.

2867. And I believe you became acquainted with a patent for extinguishing fire by means of steam while you were at Manchester?—Yes; patented by a Mr. Robert Hollingdrake for mill purposes.

2868. What was he?—An ironfounder in Stockport.

2869. And can you tell us anything about the successful application of this patent?—It answered the purpose to a certain extent, but it gave a good deal of trouble from the fact that the steam spread about so much that it rusted the machinery; so that if there was a fire in one corner of the room all the machinery throughout the room was rusted; and consequently I believe it fell into disuse. Another difficulty, and a serious one in my estimation, was that in a large room where there was a very large area of cooling surface the steam condensed very quickly, I consider that in any place where there is a large number of rooms, or a large cooling surface such as skylights or open iron roofs, that would be fatal to the system, because the steam would condense readily and not have any effect on the fire.

2870. And I suppose if the windows were knocked in, it would have the same effect in that respect?—Yes, or if there were staircases open that would convey the steam away.

2871. You are not able to tell us of this invention having been used for any length of time successfully?—I cannot say that it has been used successfully. I have lost sight of the matter for some years; but it struck me that it might be used successfully on board ship where the hatchways can be battened down. In a confined space it might be used successfully.

2872. Then how would you propose to fit a vessel with it?—By running pipes in various places.

2873. With holes perforated in them?—Yes, and commanding cocks, so that steam would only be turned into such places as was necessary.

2874. I suppose you would hardly expect that the steam would permeate through a large stock of coals very far, particularly if there were much small among them?—No; but if the pipes were carried in various directions I am of opinion that the fire might be held in subjection for a considerable time, instead of breaking out and destroying the whole cargo.

2875. I see that you suggest our examining the patentee?—I thought that he might give more information about it, and might tell you where the difficulties were in applying it.

2876. I suppose you are aware that there are a good many patentees that have ideas about putting fires out ?—I am aware of that.

2877. You have no particular knowledge of your own in reference to the application of steam in putting out fire ?—Excepting on a very small scale. I have tried it on a small scale and found it very successful. In fact the small scale on which I tried it was with a kettle and a candle and also a gas burner. I found it very successful when applied to a strong flame of gas. I have also tried it in a chamber where the steam was at a very low pressure so that I could bear my hand on the windows, and successfully put the fire out. This chamber was 16 feet long by 6 feet wide, and 10 feet high.

2878. You have never had any risk of the Houses of Parliament being burnt down from spontaneous combustion in your stock of coals, and used this means of putting the fire out ?—No.

2879. Or have you on any other occasion dealt with fire in masses of coal, putting it out, whether by steam or otherwise ?—No.

2880. (*Mr. Cory.*) I suppose the steam would require to be of some considerable pressure in order to produce an effect on fire ?—No.

2881. Supposing there was a fire in this room, and it was filled with steam, would it have any effect on the fire ?—Yes, I think that at a very low pressure it would answer.

2882. Such a pressure for instance as would not break the windows ?—Yes ; the pressure of the steam was scarcely anything above the atmosphere.

2883. (*Mr. Icely.*) It would not be hermetically sealed ?—No. Of course steam would escape through the keyholes and various chinks.

2884. (*Mr. Abel.*) The arrangement which you have referred to, the system of perforated pipes, seems to be rather an obvious mode of applying the steam. Could you point out any special feature in this particular patent ?—As it is necessary in cotton mills to keep the temperature pretty high so as to prevent the oil in very fine machinery from clogging, heating by steam pipes running all round the rooms is adopted, and the invention consisted in making those pipes with a diaphragm through the centre, so that one half acted as the ordinary steam or heating pipe, and the other half was perforated so that at any time steam could be turned into this perforated pipe and diffused through the room.

2885. The invention was chiefly applicable to cotton mills, or factories of that kind ?—Yes, where steam was already in existence.

2886. Probably a much more simple arrangement would apply the steam in the hold of a vessel ?—Yes, much simpler.

2887. (*Mr. Young.*) Have you ever reflected, with regard to this invention as applied to coal-laden ships, on the cost and trouble that it would give ?—Very much would depend upon the construction of the vessel and the nature of the bulkheads. If you get the steam into small spaces it would be very much simpler than having one large hold. I should consider that in a steam collier, where boilers are constantly under steam, the cost of fitting up an apparatus of this description would be, perhaps, such a matter as 5*s*. per ton burthen.

Mr.
W. J. Prim.

15 Feb. 1876.

2888. Unfortunately from all we have seen and heard it is not on board steam colliers and in short voyages that the danger is apprehended, but on board large vessels and vessels going on long voyages, and not merely destined for coal, but going for the purpose of bringing home other cargoes ?—It that case it would be necessary to have a boiler on board ; that boiler could be used for cooking and general work on board.

2889. With a donkey-engine, you mean ?—Yes ; for working capstans and hoisting in and out cargo, &c.

2890. (*Mr. Fenwick.*) Have you any proposition to make as regards the fitting of a coal-laden vessel with regard to these pipes of which you have spoken ; do you propose running them through the centre of the ship or the sides ?—I would keep them as low as possible (as the steam will naturally rise) in the bilges, and in places where they would be accessible when the cargo was out, and in some cases, if possible, accessible when the cargo was in ; and I would suggest having cocks so that steam could be turned on in sections. If it was known where the fire was located then the nearest section to that could be turned on.

2891. By means of pipes leading up to the deck ?—Not necessarily to the deck ; to places where they would be accessible, to such parts of the ship where a person could get down to the bottom without going down through the cargo.

2892. (*Chairman.*) When a vessel is loaded with coals she is nearly as full as she can hold, you would therefore have to make tunnels to get down to the coals ?—In some cases there are portions of the vessel running very fine aft and forward where there are no coals.

2893. As a rule they are filled up within a foot or two of the deck all over the body of the ship. You would see that there would be considerable expense if you were to make tunnels to get to the cocks ?—Decidedly, if it were necessary.

2894. (*Mr. Icely.*) There would be no difficulty in fitting the cocks with spanners leading to the upper deck, would there ?—Not the least.

2895. (*Chairman.*) You would see the difficulty there would be in preventing the coal dust from getting into your pipes ; you would have to cover them with something in order to prevent that ?—Yes. Some provision should be made in the nature of a shield, so that the steam would have to pass some short distance before it came into contact with the cargo.

2896. You would have a wooden box and holes in the sides of it, and the top covered, I suppose ?—Yes, something of that sort. With a properly constructed shield any little dust that there was would be blown away, so long as it was not forced or pressed into the orifice of the steam pipes. The pressure of steam would be sufficient to blow that away.

2897. Have you anything else to say on this subject ?—I would observe that I consider that a hose could not be worked very well with steam in it, even if you had a hose on deck. A leather or canvass hose could not be worked advantageously with steam, because if there were the least hole in the hose the steam would escape rapidly ; and in binding up the hose steam would not be so easily dealt with as water.

2898. Have you anything further to add to your evidence ?—I think not.

The witness withdrew.

Adjourned.

INDEX.

A.

Abel, Professor.
Scientific paper by, relative to spontaneous combustion and explosion, *Rep.* p. vi., xxvi.

Aberdare.
Anthracite in Aberdare Valley, 830.
Spontaneous combustion of coal at, 966.

Analysis of Coal.
By Professor Ferguson, *App.* p. 109.

Anderson, Mr. Matthew. (*Analysis of his Evidence.*)
Is a ship owner and superintending engineer at Leith, 2731–2733.
Has seen many ships loaded with coal, and has superintended loading of coal in ships' bunkers, 2734–2738.
Spontaneous combustion of coal; it arises from presence of pyrites, or brasses, in contact with water; fire must ensue at a certain time, 2738–2741, 2745, 2750, 2751, 2769.
Ventilation of coal; only useful where coals give off much gas; may prevent explosion, not combustion; would not put pipes through coal except to ascertain temperature, 2738–2762, 2795, 2796.
Coals never take fire except when put on board in a damp state, 2748, 2749.
Water is not one of the elements of coal; it may absorb water, 2763–2768.
Scotch coal; liability of some to spontaneous combustion, 2767, 2770, 2771.
Desirability of applying carbonic acid gas to heated coal cargoes, 2743, 2760, 2772–2776.
Numerous instances of spontaneous combustion in waste coal-heaps seen by witness, 2739, 2777–2779.
Instance of firing of coal in ship's bunker; due to damp in coal, and heat from boilers, 2780–2794.

Anthracite.
In the Aberdare Valley, 830.
Not liable to spontaneous combustion, 869.

Anti-breakage Boxes.
See *Shipment of Coal.*

Armington, Col. J. H.
On firing of coal-stores, *App.* p. 111.
His register of the temperature of coals, *App.* p. 113.

Barbadoes.
Combustion of coal-store at, 897, 917.

Barrow for Loading Coals.
See *Shipment of Coal.*

Bermuda.
Combustion of coal-store at, 654, 663, 680.

Beynon, Mr. Thomas. (*Analysis of his Evidence.*)
Is a magistrate at Newport, and a shipowner and coal-merchant, 1381, 1382.
Has shipped coal for 15 years; last year perhaps 80,000 tons, 1383, 1384.

Beynon, Mr. T. (Evidence of)—*continued.*
Has known three cases of spontaneous combustion, 1386.
Case of the "Usk;" she carried smelting coals, from Swansea; the coals were wet; they were tipped; they were ventilated by a kind of square pipe running through the ship, battened over; they caught fire when 88 days out, 1386–1403.
Case of the "Herbert Grahame;" spontaneous combustion occurred after she had been out about 100 days; she carried smelting coals, small, and containing much iron pyrites; they were shipped wet, and by the tip, 1386, 1404–1424, 1480, 1481.
Has no faith in the ventilation of smelting coals; for steam coals it is sufficient to keep the hatches off, without any longitudinal ventilation, 1395, 1422, 1433–1436, 1495.
Difficulty in accounting for spontaneous combustion; instance cited, 1400.
Shipping coal; approves of the tip system; shipping in casks or barrels would be a sure preventative against spontaneous combustion; Newport method, 1418, 1423–1440, 1464–1479.
Smelting coal, containing iron pyrites, shipped wet, is very liable to take fire; bituminous coal is used for smelting, 1419–1423, 1450, 1456, 1485–1490, 1496–1503.
Case of the "Minnie Grahame;" she was lost under similar circumstances to the "Herbert Grahame," 1386, 1404, 1425, 1480–1482.
Application of carbonic acid gas to fire in the hold of a ship; it could only answer where the air was totally excluded, 1424, 1427, 1428.
South Wales coals; first-class steam coals are not likely to take fire; different kinds of smelting coal; many have never taken fire, 1432, 1456–1463.
Does not know a case of spontaneous combustion in north country coal, 1432.
Premiums on coal-laden ships; they have a tendency to go up, 1441–1449, 1483, 1484.
Has known several cases of explosions in Cardiff, 1491–1492.

Birkenhead.
Regulations for loading coal at, *App.* pp. 124, 125.
Statistics of coal vessels sailing from, *App.* p. 127.
See *Tables.*

Bisulphide of Iron.
In coal, 1815.

Bladon, Mr. John. (*Analysis of his Evidence.*)
Is a coal shipper at Newport, 1504–1506.
Shipping of coals; at Newport it is done by a shoot; they are shipped in about the same time as formerly; shipping in haste is not a cause of combustion or explosion, 1507–1509, 1540–1543, 1572–1575.
Newport coal; it consists chiefly of steam and house coal; very little smelting coal, 1510–1512, 1514, 1515, 1540–1559.
Steam coal is less liable to spontaneous combustion than house coal, which contains more iron pyrites, 1511, 1518, 1524–1527, 1555–1559, 1562, 1563.
Ships that carry Newport coal are of almost all classes, 1513, 1516, 1517.
Has never heard of cargoes of large well-shipped steam coal taking fire, 1521.
Large quantities of coal are more likely to take fire than small, 1521, 1550.
Attributes spontaneous combustion of coal to its being shipped wet; this might be prevented if expense were no object, 1522–1527.
Ventilation, where coal is shipped dry, might prevent combustion; with wet coal it would promote combustion, 1528–1531.
Stacking of small coal; in the pit, combustion occasionally takes place; instance of heating of coal in store, when wet, 1532–1539, 1544–1546, 1549–1551.
Has not known of spontaneous combustion occurring in patent fuel; none shipped at Newport, 1547, 1548.
Shippers can judge what coals may be liable to spontaneous combustion, 1557, 1558, 1560, 1564.

Bladon, Mr. J. (Evidence of)—*continued.*
Does not consider the high price of coals to have affected cases of spontaneous combustion in ships, 1559–1561.
Cannot state what coals in South Wales are liable to ignition; general reports about them may be heard, 1564–1571.
All coal suffers by exposure to the weather, 1576–1579.

Board of Trade.
Unsatisfactory result of inquiries under, respecting casualties to coal-ships, *Rep.* p. v.
Statutory inquiries held by, *App.* p. 4.
Correspondence between, and local marine boards, *App.* p. 25.
Inquiries by, into cases of gas explosions, *App.* p. 41.
Present Commission recommended by, *Q.* 15–17.
Correspondence of, with Lloyd's and London Salvage Association, *Rep.* p. v.; *App.* p. 1; *Q.* 16.
Takes cognisance only of British ships, 27–30.
Takes no action regarding ventilation of coal cargoes, 2636.
See *Ships carrying Coal.*

Boilers.
Separation of coal boxes from, in Navy vessels, 616.

Boston Gaslight Company.
Coal used by, *App.* p. 114.

Box System.
See *Shipment of Coal.*

Bramley-Moore.
Regulations for working high-level coal-trade at, *App.* p. 125.

Breakage of Coal.
See *Coal.*

British Ships.
Board of Trade takes cognizance only of, 27–30.

Brooker, Mr. Orestes. (*Analysis of his Evidence.*)
Is employed at Portsmouth; was formerly inspector of coal for the Admiralty in Northumberland and Durham district, 973–976.
Shipped about 50,000 tons of coal for the Admiralty; heard of only one case of spontaneous combustion of Government coal; believes it was at Jamaica; objected to sulphurous coal; was instructed to have coal fresh raised, screened from dust, and properly shipped, 977–995, 1013–1025, 1055–1096.
Storage of coal at Portsmouth; the coals are in heaps about the dockyard, and afloat in the hulks; there is much small coal sometimes; they are exposed to all weathers; has never heard of any case of heating, 996–1003, 1026.
Is in favour of ventilating coal cargoes; the gases may be got rid of by putting tubes into the centre of the cargo, 1027–1049.
Heating of coals on board the "Crocodile;" their temperature rose to 136°, but was lowered by opening the outside ports, 1028–1049.
Coal-boxes on board ship are fitted with temperature-tubes, into which the thermometer is put every four hours, and oftener in time of danger, 1036.
Imagines that coal shipped wet, with much small in it, and not well hand-picked, would be liable to spontaneous combustion, 1050–1054.
The frequent cases of spontaneous combustion when coal was dear might have been partly due to the fact that the coal was not so well hand-picked, 1067.

Brown's Coal Lists.
Allusion to, 100.

C.

Callao Trade.
Guano vessels in, have platforms, 1338.

Cambridge (Mass.) Gas Company.
Statement from, *App.* p. 113.

Cannel Coal.

Carbonic Acid Gas.
For extinguishing fires in coal cargoes; not recommended by Commission; *Rep.* p. xxiv.; *Q.* 763, 1424, 1469, 1817, 1823, 1843, 1901, 2743, 2772.

Cardiff.
Explosion of coal-ship at, *App.* p. 59; *Q.* 1491.
Inquiries by Chamber of Commerce of, 1362.
Coal of, liable to explosion, 2829, 2834–2838, 2843.

Casualties.
See *Explosions of Coal in Ships; Spontaneous Combustion of Coal.*

Cawkitt, Captain James. (*Analysis of his Evidence.*)
Is manager of the Salvage Association at Liverpool, and chief surveyor to the local underwriters, and was previously master of ships in the Indian trade, &c., 2430–2433, 2462–2464, 2480, 2481.
His experience in shipping coal is chiefly confined to Liverpool and Birkenhead, 2434, 2500–2502.
Has observed considerable increase in casualties with Lancashire coal; the coal has been smaller than formerly, 2434–2449, 2475–2479.
Value to underwriters of Mr. Rundell's coal statistics, 2442, 2444, 2526, 2527.
Premiums on shipment of Lancashire and other coal have risen; underwriters are guided by Mr. Rundell's statistics, 2447–2449, 2500–2502, 2518–2531.
Casualties are partly attributable to shortness of time between coal being worked and put into ships; also to damp small coal and to inferior coal being shipped, 2450–2452, 2465–2476, 2494–2499.
The more coal is liable to spontaneous combustion the less it is liable to explosion, 2452, 2491.
Recent increase of accidents has resulted from heating more than from explosion, 2453.
Case of explosion on board the "Mary Amelia," loaded with South Wales steam coal; no ventilation; caused by taking below a naked light, 2453.
Casualties with Barnes' Lancashire coal, 2442, 2477–2479.
Is strongly in favour of ventilation; would have a platform, perforated, and ventilating shafts up each hatchway; recent accidents not due to ventilation, 2454–2461, 2465–2476, 2482–2490, 2516–2518.
It is most important that coal should be shipped dry, 2461, 2496.
Captains, &c. who load coal do not sufficiently calculate the danger, 2484.
Few coal ships carry a thermometer to test the temperature of the coals, which they should do, 2485, 2514, 2515.
South Wales steam coal is not liable to heat, but to explode, 2491–2493.
Most burnings have occurred under the main hatch, where small coal has accumulated, 2498, 2499.
Since the accidents witness has noticed the colliery from which coals are obtained, 2503.
Increase in cases of spontaneous combustion in ships from Birkenhead and Liverpool, 2504–2506.
Coal-ships have improved of late, 2508–2510.
Shipowners take great pains in seeing to the shipping of coal, 2511–2513.

Relative to spontaneous combustion in the "Persia," *App.* p. 25.
Relating to spontaneous combustion of coal, *App.* p. 32, 109.

Covey, Mr. William. (*Analysis of his Evidence.*)
Is Chief Inspector of Machinery, and has charge of the steam reserve, 1097, 1099.
Storage of coal ashore at Devonport; some is housed, and some is not, 1100–1103, 1129–1134.
Has never seen any case of heating of coal, 1105, 1107, 1128.
Approval of ventilation of coal cargoes; there should be ventilators in the bunkers, 1110–1127.
Case of explosion of gas in the "Agincourt" and the "Devastation;" if the bunker-lids had been taken off every day explosion would not have occurred, 1112–1127.
An order has been given to the whole service that coal-boxes are to be ventilated, 1119–1123.
Has never known cases of explosion in wooden ships, where there is more likely to be admission of air, 1135.

Crane for Loading Coals.
See *Shipment of Coal.*

D.

Dangerous Coal.
See *Coal; Coals—Classes.*

Darley, Mr. William.
On prevention of gas explosions, *App.* p. 53.

——— (*Analysis of his Evidence.*)
Was formerly foreman of the yard at Chatham, and has been lately Nautical Assessor under Board of Trade, 2797, 2798.
Has had experience of cases of explosion and combustion in ships; cites instances, 2799–2804, 2850–2852.
Spontaneous combustion of coal; it arises from shipping "green" and wet coal; coals should be exposed after being taken from pit, to allow escape of gas; has not known a case in a vessel belonging to the Navy, 2805–2817, 2827, 2832, 2833, 2853–2861.
Moisture is the cause of spontaneous combustion of coal, 2815.
Coal should be put into a dry ship, 2818, 2819.
Ventilation of coal cargoes; ventilation on surface cannot do harm; only useful for coal containing no pyrites; some coal must be ventilated; approves of Royal Navy system, 2818–2831, 2842–2849.
Cardiff coal; its danger of explosion, not of spontaneous combustion, 2829, 2834–2838, 2843.
Different kinds of coal require different courses of action, 2837.
Navy engineers test their coal cargoes with the thermometer; immunity from accident attributable to this, and to their system of ventilation, 2860, 2861.

Davis, Mr. Arthur Owen. (*Analysis of his Evidence.*)
Attends from Peninsular and Oriental Company, 2580.
States number of shipments, and classes of coal shipped for Company in 1874, 2581–2585.
In 1874, had four ships burned, three of them loaded with Howard's West Hartley; and one missing, loaded with Scott's Brymbo; coal was mostly shipped in wet weather, 2586–2600, 2626.
The Company has inspectors to see to shipping of coal, 2597.
The Company prescribes no conditions as to ventilation; their inspector at Newcastle objects to it, 2601–2603, 2611, 2615–2617, 2626.
Reads memorandum relative to spontaneous combustion of coal on shore, and in bunkers of the Company's steamers, 2604.
Coal stacks of the Company; mostly covered; firing very rare; instances cited, 2604–2606.

Davis, Mr. A. O. (Evidence of)—*continued.*
Three or four cases of explosion in bunkers of Company's steamers, owing to "close" covers being kept on too long, 2604.
South Wales coal less liable to spontaneous combustion than Newcastle or North Wales coal, 2604.
Larger per-centage of casualties in 1874 than in any previous year, 2607–2610.
The Company insures its coal; rates have risen, 2612–2614, 2618–2623.
Has never compared Company's casualties with others, 2624, 2625.
Allusion to the "Corah," which went safely, unventilated, 2626–2629.

Derry, Mr. Samuel E. (*Analysis of his Evidence.*)
Was formerly inspector of coal shipped for the Admiralty in South Wales; is now a retired chief engineer in the Navy, 891–893.
Has known three cases of spontaneous combustion, all with Parson's Abbey Graigola coal; they occurred at Jamaica and Barbadoes; states particulars, 894.
Parson's Abbey Graigola coal; it is a smokeless coal from Llansamlet; iron pyrites is so intimately mixed with it as to make it liable to catch fire; it is from one particular vein (the Tyr Edmond) that the dangerous coal comes; it was simply inspected, before being ordered for the Admiralty; witness ceased to ship it after the casualties; 895–925, 936–940, 950–957.
Iron pyrites in coal; if localized in large masses, it is less liable to take fire than where it is intimately mixed; where much mixed, either damp or friction will cause spontaneous ignition, 905, 908, 923, 942–949, 962–965.
Coal should be free from small at the time of shipment; small coal assists spontaneous combustion, but it is not generally liable to fire, 909, 941, 942, 966–972.
Has never known a case of good South Wales coal catching fire spontaneously in the main body of the coal, 923, 928, 929.
Has never known a case of spontaneous combustion in patent fuel, 926, 927.
Has known cases of explosions of gas in vessels; this occurs when the hatches are put on before the cargo has given off its gas; ventilation is absolutely necessary, 929–935.
Coal was sent for trial before being admitted for Admiralty use, but the trial might have been fallacious, 953–957.
Coal shipped wet would be liable to spontaneous combustion, 958–961.

Devonport.
Storage of coal at, 1100.

Drops for Loading Coal.
See *Shipment of Coal.*

Durham.
Combustion of coal-stores at, 2739, 2777.

E.

Equator.
Analysis of results in coal-laden ships crossing the, 36–147.

Explosions of Coal in Ships.
No reliable statistics concerning, *Rep.* p. xxiii.
Surface ventilation requisite for guarding against, *Rep.* p. xxv.
Owing to marsh gas, *Rep.* p. xxviii.
Board of Trade inquiries respecting, *App.* p. 41; *Q.* 2800.
Papers from Admiralty relating to, *App.* 60.
On the Tyne, 444.
In vessels of the Navy, 581, 605, 1112.
Of South Wales coal, 929, 1942, 2492, 2829.
Not common in wooden ships, 1133.
At Cardiff, *App.* p. 59; *Q.* 1491.
In the Northumberland Dock, 1658.
Explosion mistaken for spontaneous combustion, 1959, 2036.
Of Londonderry gas coal, 2091, 2129.
At Birkenhead, 2453.
In bunkers of steamers, 2604.
Ventilation is only useful against, 2741.

Export of Coal.
From chief British ports, in 1873–75, *Rep.* p. vii.

F.

Farrer, Mr. Thomas Henry. (*Analysis of his Evidence.*)
Is Permanent Secretary to the Board of Trade, 14.
This Commission was instituted because Board of Trade's inquiries (under Merchant Shipping Act) into cases of burning of coal-laden ships failed in regard to scientific and complicated cases. Lloyd's Committee and the Salvage Association also desired inquiry by a special body, 16, 17.
Puts in papers respecting the "Herbert Grahame" and "Minnie Grahame," Abstract of Wreck Register, and two Returns, 18–25.
Board of Trade takes cognizance only of British ships, 27–30.

Fawcus, Mr. G.
On prevention of explosions in coal ships, *App.* p. 32.

Ferguson, Professor.
Chemical analysis of coal by, *App.* p. 109.

Finlay, Mr. James. (*Analysis of his Evidence.*)
Is master of a ship, and has been constantly carrying coals, 472–474.
Describes case of combustion in the ship "Alfred;" the coals were from the Tyne; they became heated when within a few days' sail of Valparaiso; the ship was lost; there was no ventilation whatever, 475–486, 508–514, 539–542.
'Tween decks a great help to a ship's ventilation, 486.
Has carried coal for 20 years in ships that were ventilated; they had wooden ventilators running fore and aft through the coal in the lower hold; attributes freedom from casualties to proper ventilation, 487–507, 515–536.
Great diversity of opinion exists about ventilation; the majority are in favour of it, 537. 538.
By applying above system of ventilation, by visiting the hold every day, and keeping off the hatches, coal may be safely carried, 543–545.

Fire in Coal-laden Ships.
Water and steam for extinguishing, recommended by Commission. *Rep.* p. xxiv.
Report on, *App.* p. 32.
Use of water for extinguishing, 761.
Use of carbonic acid, 761, 763, 1424, 1469, 1817, 1823, 1843, 1901, 2743, 2772.
Use of steam, 1933, 2867.

G.

Galloway, Captain John. (*Analysis of his Evidence.*)
Has been master of merchant ships, and used to carrying coal (mostly Scotch coal) for about 20 years, 2350, 2351, 2378–2381, 2384–2392, 2409–2411.
Has known but one case of spontaneous combustion of coal on board ship, 2352–2396, 2408.
Case of heating on board the "Malabar;" loaded with Langley Mill coal, in a wet condition; fired when 36 days out; ship was ventilated; totally lost; casualty owing to coal being damp. 2352–2378, 2381, 2382, 2398–2407, 2411, 2417–2430.
Approves of ventilation of coal cargoes; would have a platform, with a current of air underneath, 2382, 2383, 2386–2389. 2411–2416.
Casualties are increased now by coal being taken direct from pits to ships, the gas not having time to escape; also by vessels being larger, and carrying greater masses of coal than formerly, 2386–2391, 2397.
Witness had carried coal for eight or ten years without ventilating his ship, and had no casualty, 2386–2389, 2395, 2396.
Instances of Scotch coal firing, 2392–2394.
Exposure of coal to the air before shipment is an element of safety, 2428.

Gases.
Occlusion of, in coal, *Rep.* p. xxvii.
Marsh gas the source of explosions, *Rep.* p. xxviii.

Gases in Coal Cargoes.
Paper on, *App.* p. 31.
Prevention of, *App.* p. 53, 60.
See *Explosions of Coal in Ships.*

Gasworks.
Combustion of coal in, *App.* p. 109–112.

Glasbrook, Mr. John. (*Analysis of his Evidence.*)
Is a colliery owner and mining engineer at Swansea; has shipped coal for upwards of 30 years, 2179, 2180, 2345.
Swansea coals; only two are not liable to spontaneous ignition, viz., the 4-feet and the 6-feet vein; some will take fire on the wharf; some may go safely a short distance; objection to seams above Hughes's, and to the Cistern, Slatog, Bodor, Rhondda coals, &c., 2181–2186, 2189–2196, 2199, 2210, 2211, 2224–2239, 2244–2249, 2251, 2259–2262, 2285–2336, 2345–2348.
Has had one case only of spontaneous combustion—the "Alpha," 2187, 2188.
Mixing coals causes spontaneous combustion, 2190, 2244–2249, 2263–2272, 2285, 2286, 2335.
Spontaneous combustion of coal arises from its impurities, as sulphur and phosphorus, shale, earthy matter, pyrites, and "mother-of-coal," 2193–2197, 2303–2310.
Casualties occur through men not working the coal clean; desirable if they could be compelled to do so, 2197, 2198, 2200–2204. 2222, 2223, 2335.
While coal was high-priced inferior qualities were shipped; this was a cause of firing, 2201–2204, 2334.
Coal cargoes should be separated, and kept in compartments; this would be better than ventilation; a hole made in the cargo might be good, 2205–2209, 2277–2282, 2337–2344, 2349.
Coal should be shipped dry, 2209.
Shipping of coal in boxes, by steam crane, is a good mode, and does not increase cost, 2212–2222, 2254–2258.
To avoid casualties, ship coal not liable to ignite; do not ventilate; divide ship into compartments; and lower coal in boxes, 2218–2223, 2250.
Has never known patent fuel to take fire, 2240–2243.
Abbey Graigola coal takes fire if mixed with Tyr Edmond, 2244–2249.
Several cases of coal cargoes igniting when carrying Rhondda coal, 2251, 2252, 2259–2262.
Steam coal travels safely, 2253, 2327, 2328.
Coal is not liable to get mixed in working, unless it is done on purpose, 2263–2272.
Witness does not insure his ships; belongs to an insurance fund, 2273–2276. 2290, 2294.
Desirable if temperature of coal cargoes were tested by a thermometer, 2282–2284.

Glover, Mr. John. (*Analysis of his Evidence.*)
Is a chemical manufacturer at Newcastle, and a member of the Chamber of Commerce of Newcastle, 1807, 1808.
Ventilation of cargoes of north country coal; it should rather be avoided than sought for; the surface of the coals should be ventilated; iron gas pipes might be inserted in the coal for ascertaining the temperature, 1810–1814, 1817, 1821–1823, 1870–1873.
Witness's experience is confined to north country coal, 1812–1814.
Spontaneous combustion of coal; chiefly owing to its containing bisulphide of iron (in form of brasses or pyrites) with moisture, and also bituminous shale; and to the presence of finely-divided coal; pyrites finely divided favours combustion, 1815–1820, 1827–1842, 1847–1868, 1884–1900, 1923–1926.
Temperature of coal cargoes should be examined every day with a thermometer, and entered in a log, 1817.
Coal may take fire at very low temperature; some coals more likely to fire than others, 1817, 1824–1826.
No one mode of loading coal is better than another as respects combustion, 1818–1820.
Spontaneous ignition of coal is only a question of time, 1818, 1824.
Application of carbonic acid gas to heated coal cargoes; apparatus described, 1817, 1823, 1843–1846, 1865–1867, 1901–1922, 1927–1932.
Cannel coal finely divided would be likely to take fire, 1862–1864.
Moisture is one of the main conditions of the firing of coal; coals shipped wet might perhaps have a current of hot air injected through them, 1869–1876, 1916, 1935, 1936.
North of England small coal is dirtier than formerly, 1879–1883.
Heaps of coal must be large (perhaps 200 to 500 tons) to ignite spontaneously, 1886–1891.
Objection to application of steam for extinguishing fire, 1933, 1934.

Goose-neck Drop.
See *Shipment of Coal.*

Graham, Professor.
Allusion to his report on the firing of the "Amazon," 1817, 1934.

Great Western Railway.
Box system of loading coal used by, 798.

"Green" Coal.
Danger from, 2805.

Greenough, Mr. W. W.
On coal used by Boston Gaslight Company, *App.* p. 114.

H.

Hancock, Mr. Robert John. (*Analysis of his Evidence.*)
Is shipping manager to Messrs. Charles Hill and Sons, of Bristol and Cardiff, 1309.
Has shipped about 75,000 tons of coal (both steam and smelting coal) in the last ten years, 1310–1312, 1343, 1350.
Has never had a case of explosion, or of actual spontaneous combustion, 1313.
Has had one case of coals becoming heated, in the ship "Her Royal Highness;" heating resulted from the coals being placed on the bottom of the ship, and from their having got wet on shore, 1313, 1314, 1324–1330, 1344, 1345, 1354–1358.
Carries his coal on a platform 16 to 20 inches from bottom of ship; this promotes coolness and dryness; uses ventilators fore and aft, and in each hatchway; platforms are used by guano vessels in Callao trade, 1315–1319, 1337–1340, 1346.
Wet is a cause of spontaneous combustion, 1315, 1341, 1351, 1352.
Shipping coal; danger would be lessened by taking only large coal on board at first, and putting large coal in each hatchway; has generally shipped by tips, but sometimes by box-drops, 1320–1323, 1329, 1331–1336, 1353.
Understands iron pyrites to be the cause of spontaneous combustion of coal, 1327.
His captains are instructed, in a general way, to watch heating of cargoes by thermometer, and look to the ventilators, 1347–1349, 1359.
Has given particular attention lately to the subject of spontaneous combustion of coal in ships; the Chamber of Commerce of Cardiff has taken up the subject, 1359–1368.
Has found the per-centage of loss by spontaneous combustion of coal in ships to be not over one-half per cent. over the whole kingdom, 1367, 1368.
Ventilation could not be dangerous to coal, but after a fire occurred it would tend to feed it, 1369.
Pays very little extra (not more than one per cent.) for insurance now than formerly on coal cargoes, 1370–1380.

Harwood, Mr. James. (*Analysis of his Evidence.*)
Is employed at Portsmouth, 974.
Had one case of heating at a coal-store in Jamaica; the coal had got wet; it was Parson's Abbey Graigola coal; had it taken out, and, when replaced, put iron tubes into it to carry off the gas, 1004–1012.

Hatchways of Coal Ships.
Fire chiefly occurs there; should be filled with large, not small, coal, 1228, 1283, 1320–1323, 1329–1336, 1353, 2124–2128, 2498, 2556, 2561.

Hill, Mr.
Statistics by, relating to casualties to coal ships, 1365.

Hoist for Loading Coals.
See *Shipment of Coal.*

Hollingdrake, Mr. R.
His method of extinguishing fire by steam, 2867.

Hosier, Captain Henry M. (*Analysis of his Evidence.*)
Is Secretary to Lloyd's, 1.
Puts in lists of coal-laden vessels lost or damaged, and of missing coal-laden vessels; and a letter from the coal inspector of the Peninsular and Oriental Company to the Committee of Lloyd's, *App.* p. 104–108; Q. 4–13.

Howe, Mr. E.
On spontaneous combustion in coal-stores, *App.* p. 113.

Icely, Mr. C.
On combustion of coal in Plymouth Gasworks, *App.* p. 109.

Inman, Dr.
On spontaneous combustion, *App.* p. 26.

Inspectors of Mines.
Should inquire into cases of spontaneous combustion of coal, *Rep.* p. ix., xxv.

Insurance of Coal Ships.
Statistics prepared for Underwriters' Association of Liverpool, 32.
Premiums; rise of, &c., 154, 1244–55, 1270–1274, 1294–1308, 1370–1380, 1441–1449, 1483, 1484, 2052, 2097, 2273–2276, 2290, 2294, 2612, 2618, 2724.
Shippers' insurance fund, 2273.

Iron Pyrites in Coal.
See Coal.

Ironworks' Collieries.
Coal from, liable to spontaneous combustion, 2015.

J.

Jamaica.
Spontaneous combustion of coal-store at, *App.* p. 63, 64; Q. 620, 917, 979, 1004.

Jettisoned.
Heated coal cargoes jettisoned, 105.

Jeula, Mr. Henry. (*Analysis of his Evidence.*)
Is an underwriting member of Lloyd's; was formerly Honorary Secretary to the Statistical Committee of Lloyd's, 2, 3.
Puts in paper of suggestions for inquiry, *App.* p. 140: Q. 12.

K.

Kennedy, Captain William. (*Analysis of his Evidence.*)
Has commanded ships, and had experience in carrying coal, for 18 years, 2533–2536.
Has known one case of spontaneous combustion, 2537.
Instances of voyages without casualty made by witness in coal-carrying ships not ventilated, 2538, 2539, 2554.
Case of burning of "L'Aquohama;" loaded by tip; coal much broken; ventilated; totally lost; due to small coal lying under main hatchway, 2539–2545, 2571–2574.
Doubts practical worth of ventilation through coal cargoes; his owners approve of it; surface ventilation desirable, 2546–2554, 2565, 2566.
Salt water will not make coal take fire; fresh water promotes heat in coal; effect of water on cotton, 2551, 2575–2579.
Great danger arises from small coal in the hatchways; due to shipping by tip, 2555–2562.
Instances four ships firing in the hatchways after being loaded under the tip, 2556.
Registers temperature of cargo in log-book; has always experienced heat at the hatchway, even when cargo has been carried safely, 2568–2570.

Keyham.
Combustion of coal-store at, 900.

L.

Legislation.
Statutory inquiries respecting burnt coal ships, *Rep.* p. ix.; Q. 16.
Suggested only in regard to inquiry by inspectors of mines and as to specification of coal entered outwards, *Rep.* p. xxv.
Desirable for inspection of coal ships, 424, 1438.
For causing temperatures of coal cargoes to be taken, 1797.
For making men work coal clean, 2222.

Report of, on loss of the "Persia," *App.* p. 25.

McConnochie, Mr. J.
On systems of coal-shipping in South Wales, *Rep.* p. x.

McCulloch, Mr. Henry Johnson. (*Analysis of his Evidence.*)
Is Consulting Coal-engineer to the Navy, and has been connected with the coal trade more than 30 years, 696–699.
States particulars of three cases of spontaneous combustion, one with coals shipped for the Admiralty, and two with coals shipped for Madras Railway; the first casualty was owing to something external to the coal, and the others to the coals having become wet, 700–724, 848–852, 857–866, 879.
Cowpen Hartley coal; it is very free from sulphur, and one of the best coals on the Tyne, 713–717, 832, 833, 848.
Casualties in the "Numea" and "Palmyra," 713–724.
Iron pyrites in coal; all coal contains it, 717, 748, 818–833, 839–842, 865, 866.

McCulloch, Mr. H. J. (Evidence of)—*continued.*
Per-centage of casualties with which witness is acquainted is very small, 726.
Casualties in the "Rattlesnake," "Racoon," and "Megæra" were cases of heating from external causes, 727–730.
Methods of shipping coal; the best is that on the Tyne, and at Blyth and Sunderland, 731–742.
Coal should not be broken in shipping; the larger the coals the greater their value, and the less danger there is from fire, 735, 741.
Methods of transporting coal from pit to place of shipment; waggons, swing-drops, &c.; the larger the waggon the worse for the coal, 743–747, 763–817, 873.
Spontaneous combustion of coal (except anthracite) is caused by moisture, 748–750, 827, 867, 870, 872.
The increased number of cases of spontaneous combustion is owing to increase in exports, and to carelessness in shipping and ventilating coal, 751–758, 855, 856, 890.
Thorough ventilation would save coal-laden ships from danger; ventilator described, 759, 760, 834–838, 874–878, 883–890.
For extinguishing fire in coal-laden ships, water is more likely to be useful than the extincteur, 761, 762.
Objection to the system of double-screening of coal, 790, 791.
North of England system of shipping coals should be introduced into South Wales, 812.
Careful inspection of coal at the ports; comparative safety is owing to this, 843–847.
Has known many cases of spontaneous combustion of coals stored on shore; more than afloat, 853, 854.
Every coal (except anthracite) is liable to spontaneous combustion, 869.
There is not sufficient water in coal internally to make it liable to spontaneous combustion, 872.
Coals lose but little of their combustive property in the course of a voyage, 880–882.

Merchant Shipping Acts.
Unsatisfactory inquiries under, respecting burnt coal-ships, 16.

Mersey.
Letter, &c. respecting sailings of coal ships from, *App.* p. 127.

Mersey Docks and Harbour Board.

Has caused removal of boys who cleaned coal, *Rep.* p. ix.; *Q.* 1710, 1737.

Mixture of Coals.
In relation to spontaneous combustion, 641, 642, 660, 661, 670, 671, 2190, 2244–2249, 2263–2272, 2285, 2286, 2335.
For Navy use, 642, 670.

Moisture in Coal.
See *Coal.*

Montreal.
Spontaneous combustion of coal at, *App.* p. 113.

Moore, Mr. Robert. (*Analysis of his Evidence.*)
Is chief engineer, 1098.
Has never seen any heating of coal; mentions a case of spontaneous combustion in the coal bunkers on board the "Gladiator," 1108, 1109.

N.

Navy.
Instructions respecting carriage of coal in vessels of the, 616, 623.
Cases of heating of coal in ships of, 581, 701.
Approval of system of ventilation adopted by, 2828, 2844.

Newcastle.
Temperature of coals of, *App.* p. 112.

New England Association of Gas Engineers.
Paper read before, *App.* p. 111.

Newton, Mr. John Paul. (*Analysis of his Evidence.*)
- Is commander of a coal-carrying ship; has made voyages as a captain for 22 years, and met with one case of spontaneous combustion, 546–551.
- Describes case of combustion in the vessel "Lochee;" she was loaded in the Tay; the coals were saturated with rain and sea water; they were from Town Hill Colliery, Fifeshire; heating discovered after about three months; when in sight of Galle she blew her decks out from end to end; she had had her hatches off every day, and was well ventilated; only 24 hours before the explosion was anything wrong suspected, 551–556, 567–[illegible].
- Attributes casualty to coals having been shipped wet, 554.
- Has known other cases of Town Hill coal taking fire, and destroying vessels, 558–565.

New York Gas Company.
- Statement from, *App.* p. 112.

Nova Scotia.
- Papers from, respecting spontaneous combustion, *Rep.* p. [illegible].
- Temperature of coals of, *App.* p. [illegible].

Peninsular and Oriental Steam Company.
- Paper and statistics furnished by, *App.* p. 114.
- Letter from coal inspector of, to Lloyd's, 13.
- Gives no instructions respecting ventilation of coal cargoes, 1669, 1946, 2601.
- Particulars as to shipment of coal of, 1786, 1967.
- Insure coal cargoes, 2062, 2612.
- Spontaneous combustion and explosion of coal shipped for, 2580, 2604.
- Inspection of coal under, 2597.
- Spontaneous combustion of coal of, on shore and on sea, 2604.
  - See *Tables.*

Percy, Dr.
- Scientific paper by, relative to spontaneous combustion and explosion, *Rep.* p. vi., xxvi.
- Allusions to his work on fuel, 1815, 1820, 1834, 1925.

Perry, Mr. W. C.
- On causes of spontaneous combustion in coal ships, *App.* p. 33.

Plymouth Gasworks.
- Combustion of coal at, *App.* p. 109.

Poole, Mr. Henry S.
- Letter from, respecting spontaneous combustion of Nova Scotian coals, &c., *App.* p. 110.

Portsmouth.
- Combustion of coal-stores at, [illegible].
- Storage of coal at, 1105.

Premiums on Coal Ships.
- See *Insurance.*

Price, Mr. W. R. (*Analysis of his Evidence.*)
- Is a shipowner in London, 1136, 1242, 1243.
- Has had experience of two cases of spontaneous combustion of coal, in the "Calcutta" (77 days out), and the "Oliver Cromwell" (80 days out), both wooden ships; believes the coal was Howard's West Hartley; it was put on board by tips; it was much broken; it was ventilated by a horizontal shaft near the bottom; both ships were lost; report on the loss, 1137–1168, 1185, 1186, 1191–1196, 1201, 1202, 1222–1224, 1228–1231, 1256–1261, 1264.
- Burning of the "Euxine," an iron ship, loaded at the same time as the above, 1169–1172, 1186–1188, 1197, 1198.

Price, Mr. W. R. (Evidence of)—*continued.*
- Safe passage of the "Cumb." loaded about same time as above, and not ventilated, 1173, 1174, 1199, 12[illegible], 1262–1266.
- Shipping of coal by barrows is the best way; boxes the next; there is less breakage, and more ventilation through the cargo; it takes longer, and costs more, 1175–1183, 1203–1221, 1288–1292.
- Witness has carried principally from Birkenhead; method of shipping coal there is by tips and by barrows; to the character of the coal shipped there may be attributed its immunity from accident, 1178–1185, 1275–1277.
- Numerous cases of burning of vessels from the Tyne; objections of witness to experimenting with Tyne coal, 1188, 1267–1269.
- Burning of the "Berenice," having Tyne coal on board, 1188.
- If witness had to carry coal from the Tyne he would adopt the same mode of ventilation which he has applied to vessels going from Birkenhead, 1184, 1226, 1234, 1235, 1267.
- Objection of Mr. Steinson to through ventilation of coal in ships; it should be above the coal, and the hatches should be kept open when possible, 1202.
- Spontaneous combustion of coal takes place in the fine slack, 1227–1233.
- Has always instructed his captains to keep the hatches off for fear of explosions, 1236.
- Gives instructions now to try the heat of the coals with the thermometer, and record it in the log, 1236–1241.
- High rate of insurance on coal; it prevents its being carried in high-class ships; witness contemplates taking his own insurance risk, 1244–1255, 1270–1274, [illegible].
- Has carried Cardiff coal, and always ventilated it, 1278–1282.
- As an insurance broker, witness has insured ships in which cases of combustion have occurred, 1294–1301, [illegible].
- Danger of heating of small coal in the main hatchway, 1151, 1166, 1228–1233, 1283–1287.

Prim, Mr. William Jacob. (*Analysis of his Evidence.*)
- Is Resident Engineer to the Houses of Parliament, and was formerly Chief Assistant to the Manchester Steam Users' Association, 2862–2866.
- Describes Mr. Robert Hollingdrake's patent for extinguishing fire by means of steam; it might be successful on board ship; the vessel might be fitted with perforated pipes, &c., 2867–2898.

Pyrites in Coal.
- See *Coal.*

Q.

Questions by the Commission.
- Proposed to be put to masters of coal vessels in which casualties have occurred, [illegible].

R.

Resiniferous Shale.
- In Tasmania, *Rep.* p. xxvi.

Richters, M.
- Experiments by, on weathering of coal, *Rep.* p. xxvii.

Roberts, Edmund Squire. (*Analysis of his Evidence.*)
- Is inspector of coal shipments at Cardiff for the Peninsular and Oriental Company; has inspected about 1,000,000 tons of coal and 700 ships, 1937–1941.
- Has had one case of explosion, none of spontaneous combustion, 1942, 1943, [illegible], 2057–2060.
- Best steam coal is not subject to spontaneous combustion, 1944, 1945.
- Objection to through ventilation of coal cargoes; coal stores on land should be ventilated; ventilation should be on the top, [illegible].
- Does not believe in spontaneous combustion, 1959–1963, [illegible].
- Shipment of coal; is particular with regard to avoiding breakage; system described, 1967–1979, 2042–2056, [illegible]–2071.
- Storage of coal at Alexandria; each stack was ventilated by a tunnel through the coal to prevent spontaneous combustion, [illegible].
- Only the best coals should be sent on long voyages, [illegible].

Roberts, E. S. (Evidence of)—*continued.*
South Wales coals; some are dangerous from containing iron pyrites, as No. 2 Rhondda, most Monmouthshire coal, &c., 2004–2039.
Ironworks coal is liable to spontaneous combustion, 2015–2035, 2072.
Has never heard of patent fuel catching fire, 2040, 2041.

Royal Mail Steam Packet Company.
Information furnished by, *App.* p. 114.
See *Tables.*

Rundell, Mr. R. Cooper.
On sailings, &c. of coal ships from the Mersey, *App.* p. 127.
——— (*Analysis of his Evidence.*)
Is Assistant to Secretary of Underwriters' Association of Liverpool, 31.
Has prepared statistics with a view to discover probable cause of spontaneous combustion of coal in ships, and afford means of estimating the increased risk, 32–36, 100-105.
Greater number of fires occur about the 60th day after leaving port; fires have occurred in most of the varieties of coal exported; fires occur in the cargoes whether coal be ventilated or not, and whether loaded in summer or winter, by tip or basket; statistics in illustration of foregoing, 37–57.
Certain amount of moisture present in all coal, 37.
Classification of coal ports, and comparison of sailings and casualties, 46–57.
Cannel is a safe class of coal, 51, 52.
Orrel coal bears a high character, 52.
Crow Orchard coal thought to be liable to spontaneous combustion, 53.
Bituminous coals are avoided by some underwriters; accidents with them, 54, 55.
Casualties in connexion with coal shipped from Lancashire and South Wales ports, 55, 73, 76.
Tonnage of ships (sailing and steamers) in which casualties have occurred; time between sailing of ship and indication of heating, 58–64.
Summer sailings are the most dangerous; most casualties have occurred in September and October, 65–69, 94–99.
Effect of temperature; when and where heating first discovered, 69, 70.
Selected sailings, and number of heatings to number of voyages, 71–73.
Shipment of coal by hand and tip; shipment by tip breaks the coal, and increases the danger; shipment by barrow preferable, 74–76, 107, 108, 114–117, 157–168.
Coal with which casualties have occurred, and ports from whence shipped, 77–86.
Casualties do not show clearly the comparative liability of coal to spontaneous combustion, 87.
Accidents in iron and in wooden vessels, 88–93.
Ventilation of vessels in which casualties have occurred; difficult to say whether a vessel is sufficiently ventilated; certain system recommended by underwriters' surveyors; shutting up coal would conduce to its combustion, 90, 91, 118–120, 141.
Casualties in shipment of lignite from Marseilles, 106.
Casualties, other than burning, occurring to coal-laden ships, are rare, 109–111.
Nothing to show whether double-screened coal would fire sooner than single-screened, 112, 113.
Cases of coal becoming pasty from exposure, while waiting for ships, 120, 121.
Dampness of coal, and spontaneous combustion, 122–125.
Great increase of casualties from combustion of coal afloat in 1874; casualties not on the increase generally; connexion between casualties and increased demand for coal, 126–136.
Casualties proceed from condition in which coal is shipped, 135.
Connexion of casualties and the labour question; increased cost of labour; pitmen not fined now for sending up bad coal, 137–139.
Casualties are to be attributed to what occurs before the coal is shipped, 140, 145.
Coal is carried generally in a better class of vessel than formerly, 142–144.
Comparison of longer and shorter voyages; longer voyages afford a good specimen, 146–153.
Premiums have risen for short, as well as for long voyages, 154, 155.

Rundell, Mr. R. C. (Evidence of)—*continued.*
Coal agents who have a name to keep up are particular as to their shipments, 169.
Allusion to Coal List of, 2442, 2527.
See *Tables.*

S.

Salvage Association.
See *Liverpool Salvage Association; London Salvage Association.*

Sandeman, Captain Alfred P.
On coal cargoes, *App.* p. 139.
——— (*Analysis of his Evidence.*)
Was connected with East India Navy; afterwards Surveyor to London Salvage Association; subsequently Surveyor in Marine Department of Board of Trade, 2630–2637.
Has specially attended to question of ventilation of coal ships; approves of thorough or no ventilation; describes various systems; would ventilate to prevent cargo from getting heated; approves of ventilation being enforced by law; increased freight might have to be charged, 2634, 2641–2654, 2669–2730.
Board of Trade take no action in respect of ventilation, 2636.
Many shipowners object to ventilation, but some are in favour of it, 2647, 2729.
Impossibility of shipping coal thoroughly dry, 2652.
Large amount of pyrites in some coals; this induces combustion, 2654–2658, 2664–2670, 2689, 2690.
Instance of heating in a cargo hermetically sealed, 2658–2663.
Liverpool coal; impossible to ship it thoroughly dry; some sorts heavily charged with pyrites; less pyrites in coal shipped in the Liverpool than on the Birkenhead side, 2652–2657, 2683–2690.

San Francisco.
Casualties in coal-ships bound to, *Rep.* p. vii.

Schist in Coal.
Danger from, 1815.

Scott, Captain Henry F.
On a method of preventing spontaneous combustion of coal cargoes, *App.* p. 78.

Scott, Mr. Edward Benjamin.
Is a partner in the firm of Messrs. Gillespy and Scott; has shipped largely from all steam-coal shipping ports, principally from South Wales, 2074–2080, 2091–2095, 2147–2154.
Spontaneous combustion; danger of smelting coals; instances of steam-coal firing, 2081–2095, 2133–2135, 2138–2140.
Case of heating of coal on board the "Mary Shepherd;" carried Swansea (Resolven) coal; fired after four or five months; coal understood to have been shipped wet; it was ventilated, 2084–2087, 2168, 2170.
Liability to fire of coal shipped wet, 2086, 2177.
Case of the "Robert Watson," loaded with Coed Talon coal, containing much pyrites, 2088–2091, 2137, 2156.
Cases of the "Marlborough," "George Bradford," and "Middlesex," missing; and the "Cassange," burnt; the latter loaded with Parson's Abbey Graigola coal, 2092.
Cases of the "Princess Alexandra," carrying Londonderry gas coal, explosion; and of the "Pocahontas," carrying Hastings Hartley, burnt, 2092–2095, 2107, 2110, 2129–2132, 2154, 2157, 2158.
Insurance of ships; increase of premiums, 2096, 2097, 2116–2120.
Ventilation of coal cargoes; objection to through ventilation; where combustion is set up it would destroy the ship, 2099–2104, 2112–2115, 2121–2123, 2144–2146, 2153, 2160.
High cost of labour may induce careless picking of coal for pyrites, and so increase casualties, 2105, 2106, 2141, 2142, 2152.
Small coal is especially liable to ignition, irrespective of the presence of pyrites, 2107.
Opinion adverse to North Wales coal and South Wales smelting coal, 2108.
Has formed no conclusion as to liability to spontaneous combustion of special classes of north country coal, 2108–2111.
Danger of small coal in the hatchway, 2124–2128.
Best class of steam coal, well cleaned, is not liable to spontaneous ignition, 2143.

Scott, Mr. E. B. (Evidence of)—*continued.*
Shipment of coal; no special approval of any one system, 2161–2167.
Coals on Admiralty list, 2169–2174.
Spontaneous combustion in coal-stores, 2175, 2178.

Screening of Coal.
Disapproval of double screening, 791.

Scurr, Captain John. (*Analysis of his Evidence.*)
Is commander of the "Brenhilda;" describes the heating of coals when between the tropics and the equator; the coals were turned over and cooled; ship had good ventilators, always open; at Calcutta the coal ignited; water was pumped on it; cause of casualty most probably in the coal itself; it was called "Watson's coal;" it was tipped, but little broken, and was dry; the ship might have been as well without ventilators; heating of the coal was probably owing to its being brought too rapidly from the bottom of the colliery into the ship, 170–349.
The "County of Perth" was loading at the same time as the "Brenhilda;" she was loaded by barrow; she took fire near Calcutta, 240–245.
The "Blair Athol," loaded just after, took fire at Bombay, 241, 246–248.

Separation of Coal.
Better than ventilation, 2205.

Sheerness Yard.
Trial of Hirwain coal, &c. at, *App.* p. 62.

Shipment of Coal.
To European, as compared with more distant ports, *Rep.* p. vii.
Shipment of small coal, *Rep.* p. ix.
Systems of loading in relation to breakage, *Rep.* p. ix.
In South Wales, *Rep.* p. x.; Q. 50, 1388, 2080, 2182.
By balance tips (or drops), *Rep.* p. x.; by hydraulic tips, *Rep.* p. xi.; by hand tips, *Rep.* p. xiv.; objection to tips, Q. 76, 739; approval of them, 1418.
Anti-breakage box used in, *Rep.* p. xii.
Box system for, *Rep.* p. xii.; Q. 1331, 2212.
Crane used for, *Rep.* p. xii.
Hydraulic hoist for, *Rep.* p. xiv.
By barrow, *Rep.* p. xiv.; Q. 1180, 1203, 2539.
By spout and drop, *Rep.* p. xv.
By goose-neck drop, *Rep.* p. xviii.
Danger of shipping certain coals, *Rep.* p. xxiv.
Shipments in 1874, *App.* p. 101.
Classification of ports for, 46.
At Liverpool and Birkenhead, *Rep.* p. xii.; *App.* p. 124, 125; Q. 46, 74, 157, 1180, 2434, 2539, 2690.
From Scotch ports, 83, 2767.
In dry weather, 122.
Danger of shipping in haste, 348, 422, 1572.
Navy instructions regarding, 616, 623.
At Cardiff, 703, 1312, 1937.
On the Tyne, at Blyth, Sunderland, &c., *Rep.* p. xv.; Q. 733–817, 1138, 1580, 1647.
Waggons for, 733, 763, 873.
By swing drops, 780.
In casks or barrels, 1423.
Carelessness of officers in regard to, 2484.
At Newport, 1312, 1504.

Shipowners.

Specification for Coal Cargoes.
Legislation recommended with regard to, *Rep.* p. viii., xxv.
Form of, *App.* p. 109.

Spontaneous Combustion of Coal.
Casualties in relation to export coal trade, *Rep.* p. vi.
Cases since appointment of Commission, *App.* p. 33.
Papers from Admiralty respecting, *App.* p. 60.
Tables of cases respecting, *App.* p. 102.
Selected correspondence relating to, *App.* p. 109.
Combustion of charcoal, *App.* p. 112.
Inquiries respecting; action of the Board of Trade, *App.* p. 4; *Q.* 14–30.
Lloyd's lists respecting, 4–12.
Statistics relating to, prepared for Underwriters' Association of Liverpool, 32–169; for Peninsular and Oriental Company, 2580.
Occurs with all kinds of coal, however shipped or ventilated, 37, 869.
Takes place when about 60 days on voyage, 37.
Damp an element of, 37, 122, 554, 716, 748, 827, 867, 874.
Arises from condition in which coal is shipped, 135, 145, 748.
Cases of, in the Navy, 581, 701.
Mixing coal, in relation to, 641, 670.

Spontaneous Combustion of Coal—*continued.*
Increase of casualties in connexion with, 751, 2504.
Chiefly occurs in main hatchway, 1228, 1283, 2498.
Difficulty in accounting for, 1400.
Shipping in barrels would prevent, 1424.
Increased by large masses, 1521.
At the pit, 1532.
Not liable with patent fuel, 1547.
Cases of explosion mistaken for, 1959, 2036.
Less liability of, with coal liable to explode, 2452.
May be caused by fresh, not salt, water, 2551, 2575.
Memorandum relative to, 2604.
Arises from shipment of "green" coal, 2805.
Earthenware tubes might be inserted in coal-cargoes as a test for prevention of, 2824.

Spout for Loading Coal.
See *Shipment of Coal.*

Stacking of Coal.
Methods of, 620, 664–669, 690–692, 996–1003, 1026, 1532–1539, 1549–1551, 1980–1998, 2604.

Statistics of Coal.
None reliable, in relation to explosionp, *Rep.* p. xxiii.
Stored on shore, *App.* p. 115.
Carried by Birkenhead vessels, *App.* p. 127.
Prepared for Liverpool Underwriters' Association, 32–169,
Respecting combustion in coal-ships, 32, 57, 100–105. 146.
Carried on Atlantic voyages, 146.
Mr. Hill's, 1365.
Mr. Rundell's, 2442, 2444, 2526, 2527.
Peninsula and Oriental Company's shipments, &c., 2580–2585.
See *Lloyd's; Ships carrying Coal; Tables.*

Statutory Inquiries of Board of Trade.
See *Board of Trade.*

Steam.
For extinguishing fire in ships; recommended, *Rep.* p. xxiv.; *Q.* 1933, 2867.

Steathmen.
Information afforded to Commission by, *App.* p. 82.

Steinson, Captain George.
Report by, quoted, 1201.
———— (*Analysis of his Evidence.*)
Is Coal Inspector at Newcastle for the Peninsular and Oriental Company, also for the Admiralty, the India Council, the Crown Colonies, and formerly for the Egyptian Government, 1580–1583.
Statistics of coal-laden ships, 1584–1591.
Casualties to ships by burning; one case between 1861 and 1872, out of about 1,300 ships, and, since 1872, seven cases, and three possible cases, out of 215; probably not all owing to spontaneous combustion, 1592–1667, 1713–1729.
Case of the "Eliza Rulke;" coal put on board wet, 1592–1596.
Case of the "Berenice;" loaded with Davison's West Hartley, and ventilated; no cause assigned for her taking fire, 1596–1610.
Cases of the "Oneiza," "Shalimar," "Broughty Castle," and "Sidra," missing, 1611, 1637–1642, 1650–1653.
Shipping coal; use of lowering apparatus, to which the men object; use of platform to ease the fall, 1601, 1620, 1647, 1681–1689, 1755, 1761, 1768–1789.
Case of the "Moorsfoot;" loaded with Howard's West Hartley; burnt, 1615–1621.
Cases of the "Euxine," "Oliver Cromwell," "Calcutta," and "Cora;" all loaded about same time with Howard's West Hartley; the first three, which were ventilated, were lost; the last, not ventilated, was not lost, 1622–1636, 1718–1721.
Ventilation of coal cargoes; required by charter-parties; objections to through ventilation of north country coal, which is dangerous if pyrites be present; the upper surface of the coal should be ventilated, 1632–1636, 1673–1678, 1690–1705, 1712, 1730–1735.
Case of the "Ontario;" took fire, but was not altogether burnt, 1643, 1644.
Case of the "Pocohontas;" loaded with Hastings' Hartley, by the tip; ventilated; burnt, 1645–1649.
Case of the "Indian Empire;" loaded with Howard's West Hartley, 1654.
Cases of accidental firing of coal ships, 1658–1660.
Rise of price in coal has not induced owners so send out coal less carefully screened, 1706–1711.

Steinson, Capt. G. (Evidence of)—*continued.*
- Picking coals; not so well picked for pyrites in 1873–74 as previously; formerly picked by boys, who are not employed since the passing of the Mines' Regulation Act; screeners are supposed to pick out the "brasses," 1706–1711, 1736–1754.
- With high wages, workmen have been getting more careless, 1739.
- Temperature of coal cargoes should be taken daily, and noted in the log; this should be required by law, 1792–1802.
- Hartley coals are from two seams, differing considerably, 1803–1806.

"Stevens on Stowage."
- Quoted, 114.

T.

Tips for Loading Coal.
- See *Shipment of Coal.*

Tully, Mr. Charles. (*Analysis of his Evidence.*)
- Is a shipowner at Newcastle; had had two vessels burnt at sea, 350–357.
- Describes first case of burning, the "Morning Glory;" ship was loaded with smelting coals, and was properly ventilated; was burnt after being 60 days out; the coal was tipped on board at Swansea, 358–393.
- Smelting coals are more likely to take fire than steam coals; they are full of gas and difficult to ventilate, 358, 362, 367, 381–384, 421, 445
- Describes second case of burning, the "John;" ship was loaded with smelting coals from Porthcawl; burnt after being 100 days out; was loaded during wet weather, 394–420.
- To prevent spontaneous combustion, small vessels, during short voyages, should keep their hatches off; larger vessels, for longer voyages, should be properly ventilated, 421, 448–450.
- Heating of coal is attributable to coals being shipped fresh from the colliery, 422, 423.
- Law respecting ventilation of coal-laden ships desirable; difficulty would exist in different vessels requiring different system of ventilation, 424–440.

Tully, Mr. C. (Evidence of)—*continued.*
- Proportion of burnt vessels to whole number sent out by witness is very small, 441, 442.
- Instances of explosions on the Tyne, 445.
- Heating of steam coals shipped in large vessels, 445–447.
- Coals are better screened, and in better order for shipment, now than formerly, 452–466.
- House coals are as safe to ship as steam coals, 464.
- Witness ships between 400 and 500 cargoes a year, averaging 300 to 400 tons, 467.
- Ships coal direct from pit, in any weather, 468.
- Platforms, &c. in ore ships tend to prevent combustion; there is always a current of air, 469–471.

Abstract of, 18.

Wright, Mr. James. (*Analysis of his Evidence.*)
Is Engineer-in-chief to the Admiralty, 580.
In the last seven years there have been about five cases of spontaneous combustion and two cases of explosion in men-of-war, which have been reported, 581, 582, 615.
Describes cases of the "Euphrates," "Megæra," "Malabar," "Glasgow," "Rattlesnake," and "Daphne," in which coal took fire, 583–605.
Describes cases of the "Devastation" and "Minotaur," in which explosions of gas occurred, 605–615.
Navy order that coals are never to be shipped wet; they are to be kept dry on board; coal boxes are placed 16 to 18 inches from boilers, 616, 644–650, 653.
Standing order for taking temperature of stores; its importance, 616, 621–624*a*.
No increase of cases of spontaneous combustion in the Navy in 1873–74, 617–619.
Spontaneous combustion of coal in a store at Jamaica, 620–622; at Bermuda, 654–656.

Wright, Mr. J.—*continued.*
Coal-stores, their construction and ventilation; they are mostly covered, 620, 664–669, 690–692.
Doubts exist as to ventilation of coal boxes; Admiralty has ordered ventilation of coal boxes, in ships of any kind, by tubes leading to funnel casings, 624*a*–630, 637–640, 672–676.
Mixed coal, Welsh coal and Cowpen Hartley, were being carried when above-mentioned casualties occurred, 631–636.
Admiralty have no idea that mixing coals causes spontaneous combustion, 641–643.
No special examination made by Admiralty for ascertaining amount of iron pyrites in their coal, 657–659, 692–694.
Mixing coal is carried on during loading on board ship; experiments in mixing have been going on for some years, 660, 661, 670, 671.
Smallness of coal in connexion with spontaneous combustion, 662, 663.
Quantity of coal carried in the bunkers of a man-of-war; it varies from 20 to 300 tons, 677–679.
In the Bermuda store it was Baltimore coal that became heated; its use has been discontinued, 680–683.
During the period of the casualties referred to the number of steam ships in commission would average 170; the casualties would be about six-tenths per cent. per annum, 684–689.

ROYAL COMMISSION

ON

THE PRACTICE OF SUBJECTING LIVE ANIMALS TO EXPERIMENTS FOR SCIENTIFIC PURPOSES.

.s.) (Signed) VICTORIA *R.*

Victoria, by the Grace of God, of the United Kingdom of Great Britain and Ireland Queen, Defender of the Faith. To Our right trusty and well-beloved cousin and councillor Edward Viscount Cardwell, Our right trusty and well-beloved councillor John Baron Winmarleigh, Our right trusty and well-beloved councillor William Edward Forster, Our trusty and well-beloved Sir John Burgess Karslake, knight, Our trusty and well-beloved Thomas Henry Huxley, esquire, professor of natural history in the Royal School of Mines, Our trusty and well-beloved John Eric Erichsen, and Our trusty and well-beloved Richard Holt Hutton, esquire, greeting.

Whereas We have deemed it expedient that a Commission should issue to inquire into the practice of subjecting live animals to experiments for scientific purposes, and to consider and report what measures, if any, it may be desirable to take in respect of any such practice.

Now know ye, that We, reposing great trust and confidence in your zeal, ability, and discretion, have authorized and appointed, and do by these presents authorize and appoint you, the said Edward Viscount Cardwell, John Baron Winmarleigh, William Edward Forster, Sir John Burgess Karslake, Thomas Henry Huxley, John Eric Erichsen, and Richard Holt Hutton, to be Our Commissioners for the purposes aforesaid.

And for the better enabling you to fulfil the objects of this Our Commission, We do by these presents give and grant unto you, or any three or more of you, full power to call before you, or any three or more of you, such persons as you shall judge necessary, by whom you may be the better informed on the subjects herein submitted for your consideration, and every matter connected therewith, and also to call for, have access to, and examine all such books, documents, and papers as may afford the fullest information on the subject, and to inquire of and concerning the premises by all other lawful ways and means whatsoever.

And Our further will and pleasure is that you, or any five or more of you, do with all convenient speed report to Us, under your hands and seals, your opinion upon the matters herein submitted for your consideration.

And We do further will and command, and by these presents ordain, that this Our Commission shall continue in full force and virtue, and that you Our said Commissioners, or any three or more of you, may from time to time proceed in the execution thereof, and of every matter and thing therein contained, although the same be not continued from time to time by adjournment.

And for your assistance in the execution of these presents, We have made choice of Our trusty and well-beloved Nathaniel Baker, esquire, barrister-at-law, to be secretary to this Our Commission, whose services and assistance We require you to use as occasion may require.

Given at Our court at Saint James's, the twenty-second day of June 1875, in the thirty-ninth year of Our reign.

By Her Majesty's Command.

(Countersigned) RICH^D^ ASSHETON CROSS.

REPORT.

TO THE QUEEN'S MOST EXCELLENT MAJESTY.

In obedience to Your Majesty's commands, we have inquired into the extent to which the practice of making experiments upon living animals,—with a view to the advancement of science, or to the acquisition of knowledge available for the relief of human suffering or for the prolongation of human life,—is carried in this country,—and we have considered whether any and what measures ought to be adopted in respect of that practice. We have had the advantage of examining many eminent physicians and surgeons and physiologists of great reputation, as well as of hearing from the Secretary of the Royal Society for the Prevention of Cruelty to Animals the views of that Society. He has also laid before us several documents relating to the subject, which we have printed in the Appendix. App. IV.
We have thought it sufficient to give the references to that portion of them which consists of opinions extracted from published works or journals.

A new Society has been formed under the name of the Society for the Abolition of Vivisection. A letter from Sir George Duckett, Bart., whose name is at the head of the list of the Committee, declining to give evidence before us, will be found in the App. II.
Appendix. Mr. Holt, M.P. for the North-eastern Division of the County of 6175, &c.
Lancaster, one of the members of the Committee, has given evidence in compliance with our request. He stated to us very clearly and fully the conclusions 6170.
at which he has arrived and his reasons for them. Some observations which he 6230.
made to us on the constitution and course of proceeding of the Society will be 6287.
found in the Minutes. The honorary secretary gave evidence at considerable length. 4435.
It consisted in great part of extracts from published works, several of which we have not reprinted in extenso in the minutes,—but we have given the references so as to enable those who may desire it to refer to the originals for themselves.

Dr. Emanuel Klein, assistant professor at the laboratory of the Brown Institution, 3528.
lecturer on general histology at St. Bartholomew's Hospital, gave evidence before us. Dr. Klein has acted in the investigations which have been conducted under the medical officer of the Privy Council, and is author of the first part of the handbook to which we shall have to refer. The proof of his evidence was sent to him in the usual course for his corrections. This he returned with alterations which appeared to us to be so much at variance with the letter and spirit of the answers he had given us at his examination, that we felt ourselves unable to receive them as an authentic report of his evidence. In consequence of this refusal he has requested permission to withdraw the evidence. We have thought that this course would not be right, and we have included in the minutes the shorthand writer's note as it was originally taken, and have given in the Appendix the amended proof submitted to us, with the App. II.
correspondence on the subject.

We find that until a comparatively recent period physiology—the science 2211.
which treats of the phenomena presented by living animals—had been for some time past but little cultivated in this country, but that there has been of late years a great movement in advance. This movement is not special to physiology, but embraces physics, chemistry, pathology, and all the other branches of physical science. Laboratories for research and instruction in the sciences of light, heat, and 2678.
electricity, and of chemistry, no less than in physiology and comparative anatomy, have recently been established in Oxford and Cambridge. Physiological and pathological laboratories have been established in most of the large medical schools in the country. Much attention has been directed to the circumstance that, in the contract recently entered into for an addition to the University buildings at Edinburgh, provision is made for extensive appliances with a view to physiological experiment and instruction; while we are informed that until of recent years there was in this country no physical or physiological laboratory of any kind to which students had access, and in which they were regularly trained. There is, then, at the present time a general development of all the physical sciences,—what has been termed by one of the witnesses a great scientific revival. It is accompanied by 2215.

3090. the conviction, at which the men of science have generally arrived, that no teaching of physical science is complete unless it is illustrated by practical instruction. Physiology in particular is now for the first time assuming the position of a separate science. The professed physiologist has been until recently almost entirely unrepresented; that is to say, the physiological work has been done by persons engaged in other pursuits at the same time. The professor of physiology in Edinburgh was until a few years ago, a medical practitioner, a consulting physician; but the position is now filled by a professed physiologist, who occupies his whole time in that way. At present there are three positions in England, the tenure of which limits the holders to be exclusively professed physiologists, viz., Dr. Burdon-Sanderson's at University College (London), Dr. Foster's at Cambridge, and the Brackenbury pro-
1886. fessorship at Owens College, Manchester. It is indeed the expectation of those most
2242. conversant with the subject, that physiological investigations will more and more take
2301. place in connection with public institutions, that new chairs will from time to time
2868. be founded, and that an organised system of instruction in physiology will speedily
5420. become an important feature in scientific education.

It is evident, therefore, that the number of experiments at present performed upon living animals can by no means be regarded as the limit of the number which we are called upon to include in our consideration, but that on the contrary we must assume that the experimental method is being rapidly developed,—very
523. rapidly, Dr. Sharpey has assured us,—for, he says, that the application of physics to the phænomena of life, particularly in making exact quantitative determinations, is one of the great characteristics of modern physiology.

In laying before Your Majesty our opinion as to the extent to which the practice now prevails, we have not the means of referring to statistical returns except as regards the experiments performed in the physiological laboratories attached to medical schools and universities; and there can be little doubt that experiments have been and now are performed occasionally by private persons, of whose number we
2[illegible]7. are able to form no accurate computation. The number of persons systematically engaged in the performance of them does not appear to be more than from 15 to 20 at the utmost. Such statistical information as we have been able to obtain will be
App. III. found in the Appendix.

A very strong feeling has been excited in the country, within the last two or three years, on this subject.

On the occasion of the assemblage in London in 1874 of delegates from foreign countries connected with associations for the prevention of cruelty to animals, Your Majesty was graciously pleased to give public expression to a warm interest in the success of
App. I. their efforts,—to a horror in hearing and reading of the sufferings which the brute creation often undergo,—to a fear that this is sometimes the case from experiments in the pursuit of science,—and to a hope that the entire advantage of those anæsthetic discoveries, from which man has derived so much benefit himself in the alleviation of suffering, may be fully extended to the lower animals.

We believe that these are the sentiments of Your Majesty's subjects generally. The present feeling appears to have been excited by a variety of concurrent circumstances, such as the movement, of which we have already spoken, involving, it is generally believed, a great increase, present and prospective, in the practice of subjecting live animals to experiments;—the introduction at some of the principal medical schools of experiments, by way, not of original research only, but of demonstrations to students given in public;—and the circulation here of the reports of many very painful experiments, mainly taken from foreign publications;—but most of all by the appearance in 1873 of a work called a Handbook of the Physiological Laboratory, professing to be intended for beginners, and describing many very severe ex-
2284. periments. It is admitted in his evidence by the editor himself, that no adequate means
2333. had been taken either to explain the meaning which was intended to be conveyed by the word "beginners," viz., beginners in the special study of physiology,—or to make known what he told us is the general understanding in all English laboratories, that anæsthetics should be administered in the great majority of cases, and in other cases painful experiments should not be repeated merely to demonstrate truths already
2367. sufficiently established. This, it was presumed, would be taken for granted. He
2368. expressed his regret that this feeling should have been occasioned by the publication
2369. of the book, and gave us reason to expect that he would take measures, to which he referred, for correcting the impression it had produced. Much attention also has been drawn to a series of experiments which were recently performed by Dr. Ferrier in the laboratory of Dr. Crichton Browne, at the West Riding Lunatic Asylum at Wake-

field. These have been widely made known to the public, and it has been asserted that from their nature they could not have been performed under anæsthetics. If that had been the case they would doubtless have been extremely painful, but they were performed in the presence of many medical men, and we are positively assured by Dr. Ferrier and Dr. Crichton Browne that all the animals experimented upon were 3172. first rendered insensible to pain, and were kept so during the operations. Much 3193. allowance must be made for the misunderstanding and exaggeration to which reports 3228. on such a subject are necessarily liable when not critically examined and not based 762. upon the evidence of eye witnesses.

Medicine rests upon the triple basis of clinical observation, and patho- 1444. logical and physiological research,—and the practice of operating upon the living subject appears to have been coeval with the commencement of the pursuit of medical science, and to have been applied not only to animals, but at some times even to men, without regard to the suffering it involved. Speaking of the time of Celsus, Bacon, in the Advancement of Learning, says:—"As for the passages and pores, it is "true what was anciently noted, that the more subtle of them appear not in anatomia, "because they are shut and latent in dead bodies, though they be open and manifest "in live; which being supposed, though the inhumanity of anatomia vivorum "was by Celsus justly reproved, yet in regard of the great use of this observation, "the inquiry needed not by him so slightly to have been relinquished altogether, or "referred to the casual practices of surgery, but might have been well diverted upon "the dissection of beasts alive, which, notwithstanding the dissimilitude of their "parts, may sufficiently satisfy this inquiry."—Book II. Title X. 9.

Galen, in his writings, describes with painful particularity the great number of 499. the tables he had on which animals might be fastened, and the severe experiments which he used to perform upon them.

After the revival of letters, the practice was extensively pursued in the 16th and 17th centuries. Harvey appears to have been almost entirely indebted to it for the ever memorable discovery of the circulation of the blood. 394. "When," he says, "I first gave my mind to vivisections, as a means of "discovering the motions and uses of the heart, and sought to discover these from "actual inspection, and not from the writings of others, I found the task so truly "arduous, so full of difficulty, that I was almost tempted to think with Fracastorius, "that the motion of the heart was only to be comprehended by God. For I could "neither rightly perceive at first when the systole and when the diastole took place, "nor when and where dilatation and contraction occurred, by reason of the rapidity "of the motion, which in many animals is accomplished in the twinkling of an eye, "coming and going like a flash of lightning, so that the systole presented itself to "me, now from this point, now from that, the diastole the same; and then every-"thing was reversed, the motion occurring, as it seemed, variously and confusedly "together. My mind was therefore greatly unsettled, nor did I know what I should "myself conclude, nor what believe from others. I was not surprised that Andreas "Laurentius should have said that the motion of the heart was as perplexing as the "flux and reflux of Euripus had appeared to Aristotle. At length, and by using "greater and daily diligence, having frequent recourse to vivisections, employing a "variety of animals for the purpose, and collecting numerous observations, I thought 138. "that I had attained to the truth." The deer in the Royal Parks were placed at his disposal for this purpose; and when he had arrived at such a point that he felt he could demonstrate the thing, King Charles the First and his Queen, with the princesses, attended a lecture of Harvey's to witness the circulation of the blood proved upon the living body.

The great physiologist of the eighteenth century was Haller. Dr. Sharpey, after 592. speaking of Haller as one of the greatest of physiologists and the author of the greatest work upon physiology perhaps that ever appeared, quoted to us the following extract from his writings, published in the middle of the century. "But it "is not sufficient to make the dissections of the dead bodies of animals. It is "necessary to incise them in the living state. There is no action in the dead body; "all movement must be studied in the living animal, and the whole of physiology "turns on the motions, external and internal, of the living body. Hence no progress "can be made in investigating the circulation of the blood and its more recondite "movements, or the respiration, or the growth of the body and the bones, the course "of the chyle, or the motion of the intestines, without the sacrifice of living animals. "A single experiment will sometimes refute the laborious speculation of years. *Hæc* "*crudelitas ad veram physiologiam plus contulit, quam omnes fere aliæ artes quarum* "*conspirante opera nostra scientia convaluit.*" But it must not be supposed from this passage that Haller was an advocate of cruelty; for in his Life by Dr. Henry of Manchester it is recorded that he was convinced that an idle inquisitiveness or a passion for reputation could not justify our killing sensible beings in torments, and that whatever reason we may have to regard them as formed for our use, it is absurd and cruel to imagine that they are designed also to be the sport of our curiosity or vanity.

We have great satisfaction in assuring Your Majesty that at the present time a general sentiment of humanity on this subject appears to pervade all classes in this country. "It deserves detestation and abhorrence," is the emphatic reply of Mr. Darwin, when the question is put to him what would be his view of trying a painful experiment without anæsthetics, when the same
4672. experiment could be made with anæsthetics,—or in short of inflicting any pain that was not absolutely necessary upon any animal. This principle is accepted generally by the very highly educated men whose lives are devoted either to scientific investigation and education, or to the mitigation or the removal of the sufferings of their fellow creatures; though differences of degree in regard to its practical application will be easily discernible by those who study the evidence as it has been laid before
4667. us. Eminent as Mr. Darwin is in science, he has been but little conversant with
444. experiments on living animals. Of those who have practised such experiments from their earliest years of study, none is more distinguished than Dr. Sharpey. He assures the Commission that when he was a very young man studying in Paris, he went to the first of a series of lectures which Majendie gave upon experimental physiology, and was so utterly repelled by what he witnessed, that he never went back again. This was no small evidence of humane sentiment on the part of a young and ardent student at the outset of his professional career, for it involved the sacrifice of what was probably the principal object of his residence in Paris; and he does not hesitate now, in his riper years, to speak of one of Majendie's experiments in particular
474. as "his famous, it might rather have been called infamous" experiment.

2062. The feeling of the students on the subject is thus described by their teachers. Dr. Pavy says that at the commencement of his lectures he is almost obliged to give a little apology for saying that the course will be an experimental one. He sees upon the faces of the students sitting before him an expression which leads him to consider it necessary to make some explanation, and to tell them at once that no experiment will be introduced which will wound the feelings of the most sensitive amongst them. It is what he is constantly in the habit of doing, and he has found it necessary from what
2194. he has observed in his audience. He is speaking of his own class at Guy's Hospital, but this he says we may take as a fair average example of the students at all well
2898. conducted schools of medicine in the country. Dr. Rutherford told us, speaking of the students at Edinburgh, that if an animal has been suffered to come out from
4465. anæsthesia, the students at once resent it. Dr. McDonnell, speaking of the students in Dublin, says that unless he was able to give some good reason for doing away with the anæsthetics, the students would not tolerate the occurrence; the public opinion of
5468. the students would be strongly against it. Sir William Gull assures us that in a medical school anything like cruelty or indifference to suffering would be scouted by the public opinion of the students, and that he has never seen anything like indifference.

Dr. Haughton told us that he was present in Norwich on the occasion when the experiments upon dogs were performed which led to the celebrated prosecution, and the public was so much shocked that he thinks M. Magnan, who performed them,
1951. was in danger. Of this experiment we are told by Professor Humphry, who was
707. present during a portion of the time, that it was an experiment of some scientific
708. value, and the dog he saw did not appear to be suffering much. Sir William Fergusson
718. told us he thought it was grounded on incorrect views altogether, and Dr. Taylor that
1107. the experiments were of a most cruel kind and could answer no sufficient purpose.
1188.

The Secretary of the Royal Society for the Prevention of Cruelty to Animals, when
1545. asked whether the general tendency of the scientific world in this country is at variance with humanity, says he believes it to be very different indeed from that of
1549. foreign physiologists; and while giving it as the opinion of the society that experiments are performed which are in their nature beyond any legitimate province of science, and that the pain which they inflict is pain which it is not justifiable to inflict even
1546. for the scientific object in view, he readily acknowledges that he does not know a single case of wanton cruelty, and that in general the English physiologists have used
1543. anæsthetics where they think they can do so with safety to the experiment.

The recommendations which we shall humbly submit to Your Majesty will turn in a great measure upon the use of anæsthetics. The whole subject of experiments upon living animals has been, or at least ought to have been, relieved of the greater part of its difficulty by the discovery of anæsthetics and particularly of the anæsthetic properties of the vapours of sulphuric ether and of chloroform, in 1846 and 1847.

In considering what those recommendations ought to be, the first question that offers itself is, Can the practice of subjecting living animals to experiments be altogether prohibited?

To this question it may seem sufficient to reply that such an enactment must inevitably lead either to a general evasion of the law, or to an universal flight of medical and physiological investigators and students from the United Kingdom to foreign schools and laboratories, and that by this means the general treatment of animals in experiments would certainly not be altered for the better. We have not been entitled to expect the attendance of foreign witnesses; and it is obvious that our recommendations, if approved and adopted by Your Majesty, can have no force in foreign countries. We have, therefore, thought ourselves bound in fairness to avoid receiving adverse testimony in respect to foreign physiologists beyond what is to be derived from their own published writings; and it has given us sincere 2914.
pleasure to receive incidentally from competent witnesses an assurance of the 3856.
humane spirit which they have known to prevail in some foreign laboratories. 5418.
We are, nevertheless, fully justified in asserting that nothing will be gained to the 2217.
cause of humanity by compelling native students to seek their education abroad instead of at home; and it is evident that the voice of public opinion here will have an influence in the great public institutions of this country, which it cannot exercise if experiments on living animals shall be driven into private chambers to be carried 2897.
on, with inferior appliances, in conscious violation of the law.

But even if it were possible to accomplish the purpose by legislative prohibition, would it be reasonable to do so?

No one is better entitled to speak with authority on this subject than Sir Thomas Watson, not only on account of the high esteem in which he is held on professional and personal grounds, but also because the objection which prevails in many minds against all who have been accustomed to witness the infliction of pain is totally inapplicable to him. His practice, it is well known, has been that of a physician, and we learn that he has attained to his eminence in the profession without having ever himself seen an experiment on an animal at all,—making himself 33.
acquainted with those performed by others and their results, and making such use 64.
of them as he could. When the present controversy began, Sir Thomas Watson published, in a periodical of the day, his opinions upon it. This paper will be found in our Appendix; and his views will appear, in the minutes of our evi- App. III.
dence, to have been sustained by himself and supported by the general concurrence of the highest medical and scientific testimony. He begins with the general 8.
proposition that, at a small expense of suffering to one of the lower animals, we to
may obtain knowledge which enables us to prevent or mitigate pain much more 14.
severe and lasting, or even to ward off peril to life, or to prolong life in a human being. He states his opinion that for such purposes experiments are justifiable; but that they ought to be made under very great restraint, and with very careful forethought; that no such experiments are excusable if they are made at random; that to justify them at all there must be some definite object in view of a previously instructed mind; some plain question to settle, some important doubt or uncertainty to remove, some hypothesis containing the promise of service to humanity to be confirmed or confuted, at least some reasonable hope and prospect of resulting benefit; that the experimenter ought to be an absolutely good anatomist, that he ought also to be master of all that had hitherto been learnt respecting the question which he was endeavouring to elucidate, and that he should take especial care to have the proper implements and apparatus at hand for the performance of his experiments, and that he should have trained assistants who would not blunder in assisting him. Sir 22.
Thomas Watson says that, since the introduction of anæsthetics, the great majority 23.
of experiments can be rendered very nearly, if not entirely, painless. He further states that it is the decided wish of the most eminent men in the medical 45.
profession in both its branches to prevent abuse and to repress cruelty as much as possible, and he expresses his confident opinion that the Crown and Parliament may 46.
look for the support of those eminent men in any reasonable measures which they may adopt for that purpose.

In a kindred spirit, Sir James Paget, who is President of the Royal College of

Surgeons and of the Medical and Chirurgical Society, laid before us a series of resolutions which were passed at the meeting of the British Association in Edinburgh
267. in 1871. Those resolutions were:—"(I.) No experiment which can be performed "under the influence of an anæsthetic ought to be done without it. (II.) No "painful experiment is justifiable for the mere purpose of illustrating a law or fact "already demonstrated; in other words, experimentation without the employment "of anæsthetics is not a fitting exhibition for teaching purposes. (III.) Whenever, "for the investigation of new truth, it is necessary to make a painful experiment, "every effort should be made to ensure success, in order that the sufferings inflicted "may not be wasted. For this reason, no painful experiment ought to be performed "by an unskilled person, with insufficient instruments and assistants, or in places "not suitable to the purpose; that is to say, anywhere except in physiological and "pathological laboratories, under proper regulations. (IV.) In the scientific preparation for veterinary practice, operations ought not to be performed upon living "animals for the mere purpose of obtaining greater operative dexterity."

269. Sir James Paget proceeded to say that these resolutions had received his entire approval. The principle of them was adopted in a petition signed by Mr. Darwin, Professor Owen, Mr. Huxley, Sir William Gull, Sir William Jenner, the President of the College of Physicians, and several more leaders in science:—and the Bill which was introduced into the House of Commons by Dr. Playfair in the last session of Parliament must (without committing to all its provisions all who were favourable to it generally) be accepted as a proof of the readiness of men of the highest eminence in science to submit to the consideration of the legislature this difficult question.

The opinion that experiments upon animals susceptible of pain ought not to be altogether prohibited, even if it were possible to do so, has been supported before
272. us by reasoning which it is not easy to confute. All medical science, it is urged by Sir James Paget, being in a state of progress, is continually coming in sight of problems which can only be solved by experiments either upon man or upon some lower animal; so that if a patient suffering from injury or disease is brought to a physician or surgeon, the physician or surgeon must either adopt some course of cure which has become known to him from the former experience of the profession acquired by practice upon other patients or by experiment by himself or others on animals, or else he must adopt upon conjecture the remedy which he thinks most likely to be useful; that is to say, in other words, he must submit the present patient to an experiment, instead of proceeding to his treatment with the
1442. assurance which might have been given by past experience. "We save ourselves," Mr. Simon expresses it, "a great deal of needless experimentation on man by some "experimentations on the lower animals." This cogent argument is evidently susceptible of indefinite illustration from memorable cases which have from time to time occurred in history.

We propose to consider experiments upon animals under three heads,—operations involving the use of the knife,—the administration of poisonous or dangerous drugs, —and the production of disease; but before we do so it may be well to observe that in a large proportion of the experiments made for scientific purposes either no pain at all need be inflicted, as in the familiar instance of examining the circulation of the blood in the web of a frog's foot under the microscope;—or the animal is first permanently deprived of sensation, as in the study of reflex movements, of muscular irritability, of the action of the heart in cold-blooded animals, in the maintenance of the heart's action by artificial respiration, and other cases.

It may also be convenient to notice that two classes of experiment are usually spoken of in the medical profession under the common appellation of therapeutic experiments,—*i.e.*, experiments made with the view of ascertaining the properties of new remedies, or of acquiring greater precision in the knowledge of the action of those already in use. Therapeutic experiments are sometimes conducted by operations upon living animals, as when the organ, for example the liver, is exposed, in order that the effect of some agent upon that organ, whether a well-known agent or a newly discovered or suggested agent, may be open to view and be observed:—or they may consist in simply trying upon a living animal the effect of an agent which it is proposed to introduce, but which it is thought proper to try upon animals before the trial is hazarded upon man. In the tripartite division of experiments which follows, the former of these classes will be included under the head of operations, the latter under that of the administration of drugs.

Experiments upon living animals then may be considered under three principal heads, viz.:—

a. Operations:—These are performed for the purpose of examining, either for original research or for demonstration to students, the processes of life.

b. The administration of poisonous or dangerous drugs:—for the purpose of exhibiting the effect, or of discovering the cure,—or for the purpose of assisting legal investigations.

c. The production of disease:—for the purpose of observing its progress, and discovering the means of preventing, mitigating, or curing the effects of the same or similar diseases in men or animals.

a. The principal cases which have been selected for us as instances in which such operations have resulted in great discoveries have been the discovery of the circulation of the blood,—the discovery of the action of the lacteal and lymphatic system of vessels,—and Sir Charles Bell's discovery of the compound function of the spinal nerves; these three subjects have been selected for illustration because they lie at the very foundation of our present physiological knowledge. Professor Turner, of Edinburgh, to whom we have been indebted for this selection, has submitted to us notes of the history of various discoveries, and we desire to direct the particular attention of all who wish to examine the extent to which practical medicine has been improved by physiological experiment to his evidence and that of Dr. M'Kendrick on the subject. **3025.** **3025.** **3878.** **3916.**

It would require a voluminous treatise to exhibit in a consecutive statement the benefits that medicine and surgery have derived from these discoveries. Let us take for our example the discovery of the circulation of the blood, and the various improvements in the treatment of diseases, and in the safer method of performing surgical operations on the human subject, that have resulted from it. In medicine it is obvious that a knowledge of the nature of, and of the proper treatment to apply in the large and important class of diseases of the heart and blood-vessels, could not have been acquired without a knowledge of the mechanism of the circulation. In surgery, this discovery has exercised a still more direct influence; and the narrative of the improvements in practice directly referrible to it would lead us by gradual and successive stages from the time when after an amputation red-hot irons were applied to staunch the bleeding vessels, to the employment of the carbolized ligature of the present day. If Harvey's experiments, and those upon the lacteal system, were to be performed now, the animals would first be rendered insensible to pain; and even in the case of Sir Charles Bell's experiments, where sensation was the immediate subject of the investigation, by far the most severe part would also be performed while the animal was in a state of complete anæsthesia. **4538.** **3065.**

If, therefore, this inquiry had been instituted at some former time, we should have been compelled, in regard to this class of experiment, to weigh in the one scale the infliction of great and perhaps protracted suffering,—and in the other the sacrifice of knowledge, most important to mankind, but only to be looked for from experiments which involved such suffering. By the discovery of anæsthetics we have been relieved from that necessity, and our present task is to devise measures which may prove effectual to prevent abuse.

b. With reference to the administration of poisons to the lower animals, Sir James Paget brings forward the hope of discovering an antidote for snake poisons, in proof of the absolute necessity for the performance of these experiments. He mentions the many thousands of Your Majesty's Indian subjects who perish annually from snake bites. It is hopeless, he says, to make observations upon the persons bitten by the snakes, with the expectation of effecting a cure. A Government reward has been offered for the discovery of a sufficient antidote. Sir James Paget mentions the case of an enthusiast who was so sanguine of obtaining this reward that he was with difficulty restrained from subjecting himself to the bite of the cobra in proof of the efficacy of his antidote. The medical authorities of St. Bartholomew's Hospital persuaded him to transfer the experiment to some pigeons, which all instantly died. Sir James Paget says we cannot expect that short of 50 years hence a true antidote for snake bites should be found by any other means than by a series of experiments. **305.**

Of the advantages derived to man from the administration of drugs to animals by way of experiment, Sir James Paget gives an illustration in the case of that fatal and distressing malady angina pectoris, which appears quite recently to have been brought in some degree within the domain of medical control, in consequence of a discovery made from observing the effect of nitrite of amyl on living animals. It must not be forgotten that for the discovery of anæsthetics themselves both men and animals have been largely indebted to the practice now in question. **308.**

On the subject of administering poisons to animals in furtherance of medico-legal jurisprudence we examined Dr. Taylor, lecturer on medical jurisprudence and toxicology at Guy's Hospital, the author of well-known works upon the subject.
1155. Dr. Taylor has been a principal witness on all great cases of poisoning for the last 20 years. He referred us especially to his experience in the cases of Palmer, Smethurst, and Pritchard. He tells us that in the case of Palmer the conviction resulted from evidence given by himself and Dr. Rees. The effect of strychnine was
1167. at that time little known. Great difficulty was occasioned to the prosecution by the mode in which the viscera were handled after they had been taken from the body. The main point in controversy was whether it was possible that the poison could have been the occasion of the death, seeing that it was not found in the contents of the stomach. This possibility was established by experiments upon six rabbits made by
1162. Dr. Taylor and Dr. Rees. Again, Dr. Taylor referred us to a case which occurred in Suffolk 12 or 14 years ago, in which a woman was charged with having administered arsenic to her stepchild, who had clearly died from the effects of that poison. Dr. Taylor and Dr. Pavy established by experiments upon rabbits and dogs what satisfied the coroner's jury that the presence of arsenic in the stomach was not inconsistent with the statement that the death had been occasioned by the admitted application of arsenical ointment to the skin. These cases might be multiplied indefinitely.

It is not possible for us to recommend that the Indian Government should be prohibited from pursuing its endeavours to discover an antidote for snake bites :—or that without such an effort Your Majesty's Indian subjects should be left to perish in large numbers annually from the effects of these poisons; nor can we say that new medicinal agents ought in the first instance to be tried upon man, when the risk to human life might have been prevented by a previous trial upon animals. We cannot recommend that for want of such experiments criminals like Palmer should be permitted to escape, or persons suspected be deprived of the means of establishing their innocence. But we think it is most desirable that an effectual
1180. restraint should be placed upon what Dr. Taylor has described to us as purposeless
1168. cruelty,—on experiments made in excessive numbers,—on experiments made to
1169. establish what has been already proved,—on experiments attended with great pain,
1171. 1187. and defeating the very object in view,—on experiments made where a man has been desirous of bringing himself forward, or trying a new thing merely for the sake of a little notoriety.

c. The production of disease in animals has been already, and is likely to become still more, the source of knowledge prophylactic as well as therapeutic, tending in the most important degree to the prevention as well as to the mitigation and the cure of disease in the human family. There can be no simpler, or more striking
5530. example than that of vaccination for the small-pox, the discovery which was said to have saved more lives than all the wars of Napoleon had destroyed. It was by observation that Dr. Jenner discovered the immunity from small-pox of those who had contracted cow-pox. But it was by experiments upon cows that the origin of the cow-pox, a disease stated to be derived from grease in the horse, was ascertained. At the present time systematic experiments are being made under the direction of the Committee of Your Majesty's Privy Council for the purpose of establishing facts which may guide that department in taking efficient measures for the prevention or
1367. for the cure of disease. In an explanatory memorandum given to Mr. Forster when Vice-President by Mr. Simon, the medical officer, it is stated that the first aim is to obtain exact scientific knowledge of the causes and mode of attack of any disease which is in question; and in this study it frequently happens that more or less experiment has to be made as to the results which the administration of a particular influence will produce on an animal. Studies of this kind are sometimes made more immediately in the interests of man, as for instance in the case of the Asiatic cholera, and sometimes in that of the domestic animals, as in the case of sheep-pox and cattle plague, but perhaps oftenest in the common interests of both. Mr. Simon states in his memorandum that being obliged, as medical adviser of the Government, to make himself as proficient as he can in all that relates to the preventing and resisting of disease, he has felt it indispensable to have recourse inter alia to such studies. The subjects to which his investigations have been particularly directed have been cholera,
1359. tubercle, pyæmia, sheep-pox, and disinfectants. Much of the practical advice
1414. given by the Department to the public as to how they shall deal with the cases of cholera which may arise, and the precautions they shall take against the spreading of the disease, is founded on the basis of such experiments. The mode in which cholera is spread had indeed been suspected. It was a theory in the

teaching of Dr. Snow in 1849, but Mr. Simon states that since that time it has been
converted by experiment into a certainty which can be made a basis for the advice of a 1415.
Government department. Important knowledge has also been acquired in respect of
tuberculosis, that fatal malady which causes the loss of one tenth of the whole 615.
number of the human family who die in the United Kingdom. This knowledge may 1420.
be expected to receive fresh development, and to lead, if not to the suggestion of any
cure, at least to the avoidance of many of the causes which now occasion the production of the malady in the human subject.

For other instances of a like nature, we must refer to the evidence. The deduction
we draw from them is that, whether we look to the possibility of cure or to the
probability of prevention, we cannot recommend the total prohibition of experiments
of this class. It consists in subjecting a comparatively very small number of
animals to diseases not generally involving severe pain,—and from the observation
of these diseases results are likely to be derived tending to the mitigation, or possibly 615.
even the removal, of some of the severest scourges which afflict the human race.

But if it be impossible altogether to prevent experiments, and would not be reasonable to do so,—even if it were possible,—under what aspect ought they to be regarded by the law?

The law at present takes no special cognizance of the subject, but leaves it to the
operation of the statute 12 & 13 Vict. c. 92, commonly known as Martin's Act,
if indeed that Act should be held to be applicable; and the Act extends only to
domestic animals, leaving frogs, rabbits, guinea pigs, and other animals entirely
unprotected. It gives, that is, in respect of domestic animals, a remedy doubtful, 1890.
even if applicable, and not easily enforced, and in respect of others no remedy at all.

In considering the question of legislative interference, we have found in some
minds a decided prepossession against it. This appears to be connected, as in 4430.
the case of Mr. Lister, with a notion that such interference implies an imputation
of cruelty upon those who are engaged in these investigations; an imputation they
are conscious they have not deserved. From this prepossession, as we have already
seen, many of those whose position and character entitle them to the greatest weight
are wholly free; and it has almost always yielded to the consideration that if there 4431.
be a proved necessity for legislative interference to prevent abuse, such interference 2916.
will be right, provided that the teaching of physiology and the prosecution of research 5912.
by competent persons are not interfered with. Sir Thomas Watson, Sir George
Burrows, Sir James Paget, and many others have suggested the analogy of the 3220.
Anatomy Act, which has worked very satisfactorily for its purpose, and some scientific 2 & 3 Will. 4.
witnesses have expressed their opinion that the interference of the legislature is called c. 75.
for in the interest not only of humanity, but also of science. Sir James Paget considers that the present practice of the medical schools may be an error; no such experi- 320.
ments should be done, he says, except with the consent of a Committee. He thinks
it unreasonable to suppose that four members of the medical profession would join in 324.
approving an unnecessary or unreasonable experiment,—though one in his zeal might
do so, four certainly would not.

Sir William Fergusson thinks that experiments which involve suffering are carried to 1018.
a greater extent than they need be, and that there is continued and useless repetition.
His own opinion is much less favourable to these experiments than it was when he was 1031.
young, because he had much less grasp of the subject at that time. The more matured
judgment of his later years has led him to say to himself that he would not perform
some of the operations now that he performed in his earlier years. He thinks if the 1040.
public really knew what was actually going on in this country at this time, they would
expect an interference on the part of the Crown and Parliament just as much as with
reference to the disinterring of dead bodies years ago. He laid before us a protest,—on 6136.
the subject, we have been told, of cruelties alleged to have been practised at the 1030.
Veterinary College at Alfort,—signed in 1867 by the late Mr. Syme, and other eminent 1028.
surgeons, as well as by Mr. Wilkinson, the principal veterinary surgeon to the forces.

Of those who are most directly occupied in purely physiological instruction and research,—Dr. Burdon-Sanderson says that the state of things which he would like to see 2242.
established with reference to physiological research, is such as would unquestionably
discourage the making of experiments by any one, excepting by persons trained in a
school of physiology. He thinks there would be some inconveniences attaching to legis- 2348.
lation, but also that there would be even for physiology some advantages. The diffi-
culties would apply with reference to private individuals, but though he thinks it would 2349.
be an objection if private individuals should be interfered with, he does not lay great
stress upon that, because they are few and will probably become fewer year by year.

2680. As research is carried on into the more difficult parts of physiology, the investigator requires appliances of greater complexity, which are exceedingly expensive, and even if he could afford to buy them, he would have to build a place adapted for their use.
2220. Dr. Burdon Sanderson was an assenting party to Dr. Playfair's Bill, having taken an active part in regard to it, in the main approving of it, and thinking it a suitable measure.

3252. 3273. Dr. Ferrier, Professor of Forensic Medicine at King's College, London, thinks that any legislation that would retard physiological research would be a discredit to the country; but that owing to the great agitation which has taken place, it is very desirable to dissociate experiments for the purpose of original research from cruelty to animals, or the law which punishes that cruelty, and that some legislation for that purpose would be desirable.

Professor Rolleston of Oxford thinks we may bring the forces of society to bear
1298. upon the individuals. His impression of the English nature is that it is a law
1303. abiding nature, and that a pronunciamento on the side of carefulness would have its
1319. effect. He is himself amenable to the visits of the anatomy inspector, and does not feel in the least annoyed by them. He is of opinion that any experiments worth doing will be done in a public laboratory, and that no great inconvenience would arise from
1324. compelling all experiments to take place in a laboratory amenable to the visits of an inspector.

2319. Dr. Michael Foster, the Prælector of Physiology in Trinity College, Cambridge, is not prepared to go quite so far as Dr. Sanderson in the matter of the necessity for legislation, inasmuch as so far as his experience has gone in this country, he thinks
2321. there have been no abuses, and the humane sentiment which prevails might of itself be trusted entirely to prevent such abuses; but he would not object to measures which might prevent physiological experiments falling into the hands of other people of less humane sentiments if it should appear to be necessary. He does not object to legislative interference; but he does not so far agree with Dr. Sanderson as to think it desirable or necessary.

5381. Dr. Gamgee, Brackenbury Professor of Physiology in Owens College, Manchester, thinks that licenses might be given with great advantage if no vexatious spirit guided
5424. those who gave them. Having in view a considerable increase of great schools, he sees no objection to the establishment of some reasonable regulations for such institutions; and has no sentiment of an affront offered to himself in the proposal of regulations which, while they did not limit the progress of science, and the efforts of competent scientific people, should restrain the performance of operations upon living animals by incompetent persons, for no definite object, and without proper precautions.

2874. Dr. Rutherford, Professor of the Institutes of Medicine and Physiology in the University of Edinburgh, says, that it might be almost a dangerous thing for the power of granting a license to be vested in the Secretary of State: that it would be better to vest it in the councils of the Royal Society and other scientific societies, under whose jurisdiction the Inspector of Anatomy might act; and these councils might in turn be
2877. responsible to the Secretary of State. Dr. Playfair's bill, he thinks, was objectionable
2880. because it would have prohibited an experiment for the purpose of demonstration
2881. even under complete anæsthesia; and there are some minor ones which cannot well be performed under anæsthesia, such as demonstrating the action of strychnia. With these exceptions, neither Lord Henniker's bill nor Dr. Playfair's would interfere with the
2875. proceedings of a competent and well organized school like that of the University of
2887. Edinburgh; but would have the effect of interfering with persons of a totally different description, if there should be any such, who employed themselves in such
2897. pursuits. In organized schools there are securities against abuse which do not exist elsewhere.

5940. Dr. Handyside, Teacher of Anatomy in the Edinburgh School of Medicine, suggests that a system of licensing would afford the general public ample security that the practice is nowhere being carried on to any objectionable extent. He refers to the
5945. analogy of the Anatomy Act, as supporting a system of inspection. He thinks that the control should in some degree be entrusted to laymen, and proposes that justices of the peace should certify to the fitness of the persons applying for licenses, to prevent the profession being without a check.

1867. Dr. Samuel Haughton, the Medical Registrar of the School of Physic of Trinity College, Dublin, the largest school in Ireland, tells us that vivisections are strictly
1869. prohibited, and that the opinion of the educated public in Ireland is very sensitive on the subject of vivisection for the purpose of teaching classes. As regards
1874. original research, he thinks there is a good deal of second-rate physiological

practice going on, which needs control; that the conscientiousness and common sense
and savoir faire of young physiologists ought not to be trusted without it. His opinion 1917.
is that the practice should not be allowed at all for teaching purposes; that for purposes 1963.
of original research it ought to be tolerated, but regulated:—the supervision
having an analogy to, or being based upon, the provisions of the Anatomy Act.

For the opinions given by other witnesses we refer to the minutes of evidence.

But even if the weight of authority on the side of legislative interference had been
less considerable, we should have thought ourselves called upon to recommend it by
the reason of the thing. It is manifest that the practice is from its very nature liable
to great abuse; and that since it is impossible for society to entertain the idea of
putting an end to it, it ought to be subjected to due regulation and control. Those
who are least favourable to interference assume, as we have seen, that interference
would be directed against the skilful, the humane, and the experienced. But it is
not for them that law is made, but for persons of the opposite character. It is not to
be doubted that inhumanity may be found in persons of very high position as
physiologists. We have seen that it was so in Majendie. Dr. Carpenter told us that 5627.
he has seen in many instances a perfect callousness to animal suffering before the
introduction of anæsthetics, a callousness which strongly repelled him. That very
severe experiments are constantly performed cannot be doubted by those who read
the documentary evidence which has been laid before us, and the testimony of
Dr. Walker and of other witnesses who speak from personal knowledge of the
sufferings which they say have been often unnecessarily inflicted in the name of
science. Dr. Anthony, who resides in the neighbourhood of Birmingham, told us 2509.
that he is acquainted with instances of young men who carry on experiments in
private houses from mere curiosity. He considered that he had obtained his knowledge 2523.
confidentially, and declined to give us any further clue to the individuals than to say 2526.
that he has a consciousness that the thing has been done, is done, and probably will be
done. We have had some evidence that cases have arisen in which the unpractised 3466.
student has taken upon himself, without guidance, in his private lodgings, to expose 4917 to 4934.
animals to torture without anæsthetics for no purpose which could merit the name of
legitimate scientific research. Evidence of this nature is not easily obtained. So far 1687.
as our evidence goes, such cases appear to have been exceptional and abnormal, but 5076 to 5087.
the repetition of them is not on that account unworthy to be guarded against by a
legislature desirous of giving effect to the moral sense of the community at large.
Besides the cases in which inhumanity exists, we are satisfied that there are others in
which carelessness and indifference prevail to an extent sufficient to form a ground
for legislative interference. We have not thought it part of our duty, the majority of
us not having had professional training, to decide upon matters of differing professional
opinion, but we have been much struck by the consideration that severe experiments
have been engaged in for the purpose of establishing results which have been
considered inadequate to justify that severity by persons of very competent authority.
Cases may not improbably arise in future in which the physiologist may be disposed
to underrate the pain inflicted in the course of establishing results which may prove
to be trivial, or even worthless. Looking to the circumstance that a great increase
is to be expected in physiological inquiry, it appears to us most important that
some legislative control should be established to prevent abuse extending in this
direction. It is, moreover, much to be regretted that a feeling of suspicion,
and even of abhorrence, should have been permitted to grow up among a large
and very estimable portion of the public, against those who are devoted to the
improvement of medicine and to the advancement of science. Publicity is the
antidote of suspicion, and we look to the reasonable superintendence of constituted
authority as affording the means of reconciling in the public mind the sentiment of
humanity with the desire for scientific knowledge.

Our conclusion, therefore, is that it is impossible altogether to prevent the practice of making experiments upon living animals for the attainment of knowledge applicable to the mitigation of human suffering or the prolongation of human life:—that the attempt to do so could only be followed by the evasion of the law or the flight of medical and physiological students from the United Kingdom to foreign schools and laboratories, and would, therefore, certainly result in no change favourable to the animals:—that absolute prevention, even if it were possible, would not be reasonable:—that the greatest mitigations of human suffering have been in part derived from such experiments:—that by the use of anæsthetics in humane and skilful hands the pain which would otherwise be inflicted may, in the great majority of cases, be altogether prevented, and in the remaining cases greatly mitigated:—that the infliction of severe and protracted agony is in any case to be avoided:—that the abuse of the practice by inhuman or unskilful persons,—in short the infliction upon animals of any unnecessary pain,—is justly abhorrent to the moral sense of Your Majesty's subjects generally, not least so of the most distinguished physiologists and the most eminent surgeons and physicians:—and that the support of these eminent persons, as well as of the general public, may be confidently expected for any reasonable measures intended to prevent abuse.

With these views we have examined the measures which were introduced into the two Houses of Parliament in the last session, as well as the bill which has been submitted for our consideration by the Royal Society for the Prevention of Cruelty to Animals, and we now propose humbly to recommend to Your Majesty the outline of a measure which, in the interest both of humanity and of science, we think it will be expedient to adopt. But before doing so we will briefly state our views upon certain points of interest which have come before us in the course of our inquiry.

It has been proposed to enact that the object in view shall be some immediate application of an expected discovery to some prophylactic or therapeutic end, and that any experiment made for the mere advancement of science shall be rendered unlawful. But this proposal cannot be sustained by reflection upon the actual course of human affairs. Knowledge goes before the application of knowledge, and the application of a discovery is seldom foreseen when the discovery is made. The first origin of a great discovery is often, like the germ of the natural life in an animal or a vegetable, so small as to be scarcely perceptible, and yet it may contain in it the seeds of the grandest results. "Who," says Helmholtz, "when Galvani touched "the muscles of a frog with different metals, and noticed their contraction, could "have dreamt that . . . . all Europe would be traversed with wires, "flashing intelligence from Madrid to St. Petersburg with the speed of lightning? "In the hands of Galvani, and at first even in Volta's, electrical currents were "phænomena capable of exerting only the feeblest forces, and could not be detected "except by the most delicate apparatus. Had they been neglected, on the ground "that the investigation of them promised no immediate practical result, we should "now be ignorant of the most important and most interesting of the links between "the various forces of nature. . . . . Whoever, in the pursuit of science, "seeks after immediate practical utility, may generally rest assured that he will seek "in vain." As we have seen, Harvey's great discovery has been followed by remedial consequences of inestimable value, but those consequences were not foreseen by himself at the time that he made the discovery. It was, at the time that he made it, 247. "a mere scientific discovery."

Again, it has been proposed to sanction experiment for original research, but to 951. prohibit it as far as regards demonstrations to pupils. In the regulations issued by App. III. the Royal College of Surgeons, attendance upon physiological lectures is required from candidates for the medical profession; but it is stated that it is not expected that learners shall perform vivisections. We are told by Dr. Acland, Regius Professor of Medicine in the University of Oxford, the President of the Medical Council, that the question of the extent to which practical physiology is necessary for students would have been brought before the Medical Council this year, at the session which has lately closed, had it not been for the appointment of our Commission,—and that at his suggestion it was delayed until after we should have made our report to Your Majesty. It seems to us that living animals ought not to be subjected to experiment at all for any purpose of ordinary education. But in the case of professional education, as at one of the medical schools, it cannot, we think, be denied that there is much force in the argument that teaching without demonstration can scarcely be 2231. considered teaching. With respect to the medical schools we accept the resolution of the British Association in 1871, that experimentation without the use of anæsthetics is not a fitting exhibition for teaching purposes; and whatever may be the hazard of 267. evasion in private chambers, we think there can be none in the public lecture room of a great institution, when Parliament shall have established the obligation and the Crown have undertaken to enforce it.

A collateral argument has been brought forward in favour of this distinction, aiming not at the saving of pain to the animal, but at the saving of demoralization to the student. But the tendency to demoralization is connected, as the shadow with the substance, with the rightness or wrongness of the thing itself; and the evidence we have quoted above seems to show conclusively that at the medical schools where such demonstrations are exhibited under anæsthetics, the sense of humanity in the students is not in fact impaired.

It has been proposed to prohibit experiment except in public halls, to which a 3441. certain portion of the non-professional public shall at all times have access. It appears to us that this proposal would, if carried into effect, tend to frustrate the experiment as regards its usefulness, and, perhaps, as regards the effective administration of anæsthetics also, since the most essential requisite for the conduct of a delicate experiment is that the person who makes it should be free from any mental interruption or disturbance; while the presence of ignorant spectators could do nothing to secure the real humanity of the experiment. An animal may be suffering exquisite torture, and yet (so far as we yet know) the worari poison may, by its effect upon the motor nerves, prevent the exhibition of any feeling. Or, on the other hand, an animal may make every demonstration of suffering while the real sensation is destroyed. In the human subject, when chloroform is employed, or when by an 186. injury to the spine the connexion with the brain is interrupted, it sometimes happens that all the outward manifestation of pain is exhibited, when the patient afterwards 3375. disclaims having experienced any sensation of it. These effects are perfectly familiar to the instructed, but would be simply misleading to the uninitiated.

A good deal of evidence has been given as to the effect of the poison called worari or curari. This poison is very convenient to an operator, since it paralyses the motor nerves, and keeps the animal quiet. It has however been positively stated by perhaps the highest authority on such a subject, Claude Bernard, to have no effect in producing insensibility to pain. This opinion is now beginning to be disputed, but we think that until the question shall be much better settled than it is at present this poison ought not to be regarded as an anæsthetic by those who administer the law in respect of experiments on animals.

Some physiologists, while quite ready to assert broadly the principle that so far as is possible no painful operation ought to be performed except under anæsthetics, do not extend the application of the principle to cold-blooded animals. Of this kind of animal the typical instance is the frog, in which there has sprung up an import trade for the purpose of experiment, the large frog of Germany not being indigenous here. Dr. Schäfer, the assistant professor of physiology in University College, after saying 3772. that the treatment of animals there is, he is quite certain, dictated most strictly by a sentiment of humanity, nevertheless goes on to say that they consume a large number 3783. of frogs, and that the experiments upon living frogs are usually performed without anæsthetics, because the opinion is that the frog is not so sensitive as the higher 3791. animals, and he says that no special precaution is taken to diminish pain in their case. 3802. This doctrine is one which ought not to be too readily admitted, for the question is an important one; the proportion of frogs to all the other animals put together that are subjected to experiment is so great, that the frog, we are told, is called 3698. the physiologists' animal. Dr. Gamgee tells us on the contrary that when he 5414. decapitates a frog he always crushes the brain, and explains to the students why he 103. 514. thinks that the brain might otherwise retain a sensibility, which would not be retained in a warm-blooded animal.

It is said by some of the witnesses that it is very difficult to subject frogs to 4563. chloroform. But this is contradicted by the experience of others whose authority 727. is indisputable, as for example Professor Humphry and Dr. Brunton; and Dr. M'Donnell 5739. 4564. tells us that he constantly uses it for frogs and even for tadpoles, and that if a little chloroform is diffused through water, and the tadpole is put swimming about it for a few minutes, there is enough absorption through the skin to render it soon insensible, and it can be placed under the microscope for half an hour or so, and not stir. We think that in framing rules for the administration of a system, there ought to be much jealousy in too readily admitting convenient doctrines, and that proper care should be taken to insist upon the removal of the sensibility to pain 5992. even in the case of cold-blooded animals.

Mr. Pritchard, Professor of Anatomy in the Royal Veterinary College, performs most of the operations there. He says that they have no operations for the purpose 786. of experiments, and thinks it would be improper that they should. He is not aware of any being performed in this country by veterinary surgeons, does not think it is the practice, and, if it were, the principal of the college, Professor Simonds, and persons in positions like his own, would be ready to support the Government in any 790. reasonable measures of regulation. In the New Veterinary College at Edinburgh the operations are, as a rule, performed by the principal, Mr. Williams. He admits as respects one, but only one, important operation, that it is occasionally performed for teaching purposes, but he says that the animals are always rendered insensible by 6056. chloroform. The principles of our report apply to the practice of veterinary surgeons, and they, like the rest of the community, are included in the purview of the measure we are now about to recommend.

App. III. We have spoken of three bills which have been submitted to us. They will be found in the Appendix. All these bills proceed upon the basis of license by the Secretary of State, subject to withdrawal in case of abuse,—and of adequate inspection. This basis, as we have already seen, was laid down also in the evidence of Sir Thomas Watson and of other most competent witnesses, and upon it we think an effectual measure for the prevention of abuses may be founded.

1567. We were reminded by the secretary that the Royal Society for the Prevention of Cruelty to Animals is not the society established for the total abolition of experiments. The Royal Society for the Prevention of Cruelty to Animals has prepared its bill upon the supposition that experiments of a nature to cause pain are justifiable if they are performed when the animal has first been rendered wholly insensible to pain, and is destroyed before the effect of the anæsthetic ceases. The bill also provides that the place shall be registered, and that no such experiments shall be made by anyone while lecturing or giving instruction to students in classes or otherwise. The secretary has told us that the society is formed for the prevention of cruelty, and would not step out of its direction to legalize anything of a contrary nature; yet he says, in reference to a supposed case in which a great good was aimed at, and a small amount of suffering inflicted, that in such a case, even if their own bill had become law, the society would not prosecute. But we have already stated that experiments under complete anæsthesia may be used in the course of a lecture without objection on the score of cruelty; and there might be many experiments made for the purpose of original research in which the injury inflicted would be very small and the pain would be almost nil, and in which it might be more humane to permit the animal to enjoy life, than to destroy it. 1680. 1681. 4560.

The bill introduced last session into the House of Lords went upon the principle that no experiment should be lawful unless the animal were completely under the influence of an anæsthetic, and the experiment were performed in a place registered by the Secretary of State. Any person might apply to the Secretary of State for a special license to perform vivisections without the use of anæsthetics; such license was to continue for six months and no longer. On proof of any abuse, the registration of the place might be withdrawn.

The bill introduced into the House of Commons prohibited all experiments causing pain, or of a nature to cause pain, with the following exceptions, viz.:—1st. For the purpose of new scientific discovery, but for no other purpose, an experiment might be made, provided that the animal was placed and kept under complete anæsthesia. 2nd. Where for the purpose of new scientific discovery, and for no other purpose, an experiment was desired to be made in which insensibility could not be produced without necessarily frustrating the object of the experiment, it might be performed by a person holding a license granted by the Secretary of State under certain conditions.

As regards the last bill, if adopted precisely as it was proposed, it would have prevented the use of an experiment for the purpose of demonstration before a medical class in a public institution, however absolute the security for complete anæsthesia:—an object not intended to be arrived at, we presume, by the framers of the bill.

What we should humbly recommend to Your Majesty would be the enactment of a law by which experiments upon living animals, whether for original research or for demonstration, should be placed under the control of the Secretary of State, who should have power to grant licenses to persons, and, when satisfied of the propriety of doing so, to withdraw them. No other persons should be permitted to perform experiments. The holders of licenses should be bound by conditions, and breach of the conditions should entail the liability to forfeiture of the license; the object of the conditions should be to ensure that suffering should never be inflicted in any case in which it could be avoided, and should be reduced to a minimum where it could not be altogether avoided. This should be the general scope of the conditions; but their detailed application should be left to be modified from time to time by the minister responsible according to the dictates of experience. In the administration of the system generally, the responsible minister would of course be guided by the opinion of advisers of competent knowledge and experience. Dr. Playfair's bill provided a machinery for the purpose, and some arrangements of the kind proposed in that measure would be necessary. But we think it is inexpedient to divide the responsibility of the Secretary of State with that of any other persons by statutory enactment, and we recommend that his advisers should be from time to time selected and nominated by himself. Their names should be made known to the profession and the public. It may be found desirable that one of the conditions to be attached to a license should be that the experiments should be performed in some particular place; but this is a detail which may vary with circumstances, and we think it ought not to be stereotyped by statute.

The Secretary of State must have the most complete power of efficient inspection and of obtaining full returns and accurate records of all experiments made. Any place in which experiments are performed must be registered and open to efficient inspection. The appointment of an inspector or inspectors will be necessary, and we have seen that the analogy of the Anatomy Act has been appealed to by many high authorities. It is to be observed that the duties under that Act are of a nature much more mechanical than those which will be required in the present instance. The inspectors must be persons of such character and position as to command the confidence of the public no less than that of men of science.

Abuse of the power conferred by the license must, of course, render the holder liable to its withdrawal; but this will involve great disgrace; and the withdrawal of the license of an eminent man without real cause might be a serious public mischief. We have felt it necessary, therefore, to consider what steps should be taken when the question of such withdrawal may arise. We think that the holder of a license, when he shall receive notice that the Secretary of State intends to withdraw it during the period for which it has been granted, should be at liberty to demand a public inquiry; that this inquiry should be held before one of the Judges of the Supreme Court, with two competent assessors to be appointed by the Secretary of State, the Court having the full power of conducting it as a legal investigation by summoning and swearing witnesses, issuing commissions, and so forth:—that on the result of this inquiry, the Secretary of State should determine whether the license ought to be withdrawn, and when he decides in the negative, should have the power of giving the holder of the license the reasonable costs of his defence.

Magistrates ought to be empowered, on cause shown, to authorise the police to enter and search the premises of persons suspected of performing experiments without a license; and the performance of such experiments without a license should be penal.

It has been suggested that cases may occur in which an urgent necessity may have occasioned an experiment when there has been no licensed person within reach, and it has not been possible to apply for a license; such as a sudden case of suspected poisoning, arising, perhaps, in a remote place, when the experiment has been reasonably considered indispensable, for the purpose either of cure or of medico-legal investigation. Bonâ fide cases of this kind ought evidently to be free from the risk of vexatious prosecution, and this can be secured by vesting in the Secretary of State the power of putting a veto on a prosecution. 1913.

We believe that by such a measure as we have now proposed the progress of medical knowledge may be made compatible with the just requirements of humanity. In zeal for physiology, the country of Harvey, Hunter, Bell, and Darwin may well endure the test of comparison. We trust that Your Majesty's Government and the Parliament of this kingdom will recognize the claim of the lower animals to be treated with humane consideration,—and will establish the right of the community to be assured that this claim shall not be forgotten amid the triumphs of advancing science.

NATHANIEL BAKER,
Secretary,
8th January 1876.

Should it please Your Majesty and Parliament to pass any measure such as we have recommended in this Report, I desire to suggest one additional restriction which might either be embodied in the statute or endorsed by the Secretary of State among the conditions of the license which we have proposed. That restriction is, that the household animals, dogs and cats, should be exempted altogether from liability to experiments of this kind. The evidence we have taken seems to me to supply two weighty reasons for such a restriction; while a third is contained in the very nature of the relation existing between these creatures and man. The first, and in some respects the most weighty and practical reason, is this,—that there is evidently a very strong presumption that the demand of physiologists for these creatures is supplied by persons who decoy them away from their proper owners, and that in this way a strong temptation is furnished for actual theft, and all the distress which thefts of this nature too often cause. In answer to a question as to the source of supply, an eminent physiologist said (answer 2822), "I know as regards rabbits and guinea pigs, and so "forth, that they are drawn from the usual sources, that they are bought in the "market;" but when asked specially as to dogs and cats, he replied (answer 2823), "I cannot tell you where they come from. There is no proper provision in this "country by which one can obtain dogs, even for the most legitimate purposes, and of "course I am not informed as to the way in which they are obtained. They are always "paid for at a proper price." And another equally eminent witness, who had told us that in some two or three series of experiments on the cholera poison he had used considerably more than 90 cats, that being the number which he used (answer 5747) in one of those series of experiments only—replied to a question touching the source of supply, "They are supplied to me by a man;" and when further asked whether the person referred to obtained them in a legitimate way, he answered, "I make no inquiries" (5734, 5735). It would appear, therefore, that however painless the investigations conducted on dogs and cats may sometimes be, there is a special abuse to which even such painless experiments are liable, of a kind not affecting the experiments on rabbits and other creatures of which there is a sufficient market supply at low prices, namely, that the former furnish a strong motive for an illicit trade, not only degrading in itself, but causing frequently great distress to the owners of the creatures decoyed away. The second reason for this restriction with which our evidence has furnished us, is contained in an answer of Dr. Anthony, the pupil and dissector of Sir Charles Bell, who when asked whether the domestic animals are not liable to that special sensibility or "hyperæsthesia" to which civilized men appear to be so much more subject than barbarous tribes, replied, (answer 2596), "I am inclined to think so, that you have brought both under the "influence of what you may term civilization." It is true that the same witness told us, with obvious justice, that even in the same species you would find some creatures of very low, and others of very high sensibility, and that, in his opinion, intelligence might be taken as almost a measure of sensation (answer 2598); but as it will be impossible to draw fine distinctions in such cases, even if the other reasons affecting the question admitted of any such distinctions, and as it is notorious that no class of animals otherwise convenient for experimentation contains so many creatures of high intelligence, and therefore probably of high sensibility, as dogs and cats, it seems to me desirable, in consideration of this special sensibility, to exempt these members of our households from all liability to such experimentation. A third reason for this exemption seems to suggest itself from the very nature of our relations to these creatures, which we have trained up in habits of obedience to man and of confidence in him, so that there is something of the nature of treachery as well as of insensibility to their sufferings, in allowing them to be subjected to severe pain even in the interests of science. No doubt it is the intention of the measure we have recommended to reduce animal suffering to a minimum in all cases; indeed I may be allowed to say that the measure proposed will not at all satisfy my own conception of the needs of the case, unless it results in putting an end to all experiments involving not merely torture but anything at all approaching it; for where the pursuit of scientific truth and common compassion come into collision, it seems to me that the ends of civilisation, no less than of morality, require us to be guided by the latter and higher principle. But as there is no mode by which the discretion of the licensee, so long as he continues to hold his license, can be limited, I think we must assume that the subjects of these experiments will continue to be liable to a greater or less degree of suffering; and that we should try to diminish the evil involved in the infliction of that suffering to its lowest point. And if suffering is to be inflicted at all, with whatever humane economy it is meted out, it is better both as regards the evil of enduring and the evil of inflicting it, that the humble friends of man, which have been taught to obey and trust him, should not be selected as the victims. I may add that I do not find any trace in our evidence that there is a single one of the important scientific discoveries which have been represented to us as due to, or as finally verified by, experiments of this kind, of which science would have been deprived had any such limitation as this been at the time in force.

I do not include all the domestic animals in this suggestion, for two reasons. In the first place it is not necessary. The animals useful for agriculture or for purposes of food—like horses, oxen, and sheep—are a great deal too valuable, a great deal too well guarded, and for the most part a great deal too large for the purposes of ordinary physiological experiment. And in the next place, in the interest of these classes of animals themselves, it would be undesirable. The only sort of experiments to which they are commonly subjected are pathological experiments, *i.e.*, artificial inoculations with disease, made with the view of discovering some cure or some mitigation for the epidemics which periodically decimate them, like cattle plague or sheep-pox. Such experiments stand on a somewhat different footing from experiments made purely or chiefly in the interest of man himself. They are not very numerous; wherever they endanger life they are necessarily costly; and they may result in discoveries of the highest possible benefit to the races of creatures in whose behalf they are made.

I know of but one serious objection to this proposal. It has been urged upon me that by drawing a distinction in favour of certain classes of animals, the legislature would be taking a step in the wrong direction, since all humane people are desirous to see the Cruelty to Animals Act (commonly called Martin's Act), which at present protects domestic animals only, extended to wild animals; whereas the adoption of such a restriction as I have suggested would furnish, it is said, a new excuse for leaving wild animals unprotected by law. I cannot see the force of this objection, which, if it were valid, would be a very serious one, since I strongly desire to see the scope of Martin's Act extended so as to include creatures of all kinds. We should not, I think, be the less anxious to guard the less sensitive creatures from torture, because we had put the more sensitive under special safeguards. It seems to me that creatures bound to us by special ties may well and safely be permitted special privileges; indeed, that the tendency of any measure which recognised more explicitly the claims of our family dependents to be especially guarded from anything like hostile treatment, would have a generally humanizing influence on social manners, and improve instead of deteriorating the treatment even of wild animals.

RICHARD HOLT HUTTON. (SEAL.)

NATHANIEL BAKER,
Secretary,
8th January 1876.

MINUTES OF EVIDENCE

TAKEN BEFORE

THE ROYAL COMMISSION ON VIVISECTION.

Monday, 5th July 1875.

PRESENT:

THE RIGHT HON. VISCOUNT CARDWELL, IN THE CHAIR.

The Right Hon. LORD WINMARLEIGH.
The Right Hon. W. E. FORSTER, M.P.
Sir J. B. KARSLAKE, M.P.
JOHN ERIC ERICHSEN, Esq.
RICHARD HOLT HUTTON, Esq.
N. BAKER, Esq., Secretary.

Sir THOMAS WATSON, Bart., M.D., called in and examined.

Sir T. Watson, Bart., M.D.

5 July 1875.

1. (*Chairman.*) It is quite unnecessary and supererogatory to ask you any such question, but I will just get it on the notes: you are one of the physicians in ordinary to the Queen, and you have been president of the Royal College of Physicians, and a member of the Medical Council?—Yes.

2. You have recently published your views upon what you have called Vivisection?—Yes.

3. The subject on which you are invited to give evidence to-day is a little wider and is not correctly limited by the term Vivisection; it is described in the Commission as "The practice of subjecting live animals to experiments for scientific purposes?"—That is the right definition, no doubt, of the whole subject.

4. Including the subjecting of animals, for instance, to poisons?—Yes.

5. Which would not correctly be described by the word Vivisection?—No.

6. You have given, no doubt, great attention to both branches of the subject, and not merely to the one which is included in the word Vivisection?—Yes; I have thought of it in its larger sense.

7. Have you any objection to furnish the Commission with a copy of the paper which you have written on the subject?—No; it is entirely at the disposal of the Commission.*

8. In that paper it is said that "at a small expense "of suffering in one of the lower animals we may "obtain knowledge which enables us to prevent or "mitigate pain much more severe and lasting,—or "even to ward off peril to life, or to prolong life—in a "human being." Is that so?—I believe that entirely.

9. Is it your opinion that for such purposes experiments are justifiable?—That is my opinion.

10. Is it your opinion that if justifiable they should be made under very great restraint, and with very careful forethought?—Yes.

11. And that without that restraint and without that forethought they would not be justifiable?—I hold that opinion.

12. Do you hold that any such experiments are excusable "which are made at random, simply to see what will happen"?—I believe that experiments so made are not excusable.

13. Do you think that "to justify them at all there "must be some definite object in view of a previously "instructed mind?"—I do.

14. "Some plain question to settle, some important "doubt or uncertainty to remove, some hypothesis "containing the promise of service to humanity to "be confirmed or confuted, at least some reasonable "hope and prospect of resulting benefit?"—That is my opinion. I might perhaps say with respect to the experimenter that he ought to be an absolutely good anatomist, that he ought also to be master of all that had hitherto been learnt respecting the question which he was endeavouring to elucidate, and that he should take especial care to have proper implements and apparatus at hand for the performance of his experiments, and that he should have trained assistants who would not blunder in assisting him.

15. Do you think that any man is justified "in "making any painful experiment upon a living "creature who does not possess the skill, judgment, "intelligence, and previous knowledge" to which you have pointed?—I believe that no man is justified in making such experiments who is not so qualified.

16. And that "all possible care should be taken by "the experimenter to prevent the frustration of his "object through want of foresight and needful pre-"paration," such as that which you have pointed to?—Yes.

17. Do you think that when he has already thoroughly satisfied himself of the solution of any physiological problem he is justified in repeating the experiments, however mercifully they may be conducted?—I believe he is not justified in repeating experiments after he has satisfied himself upon the question at issue.

18. Now even for those purposes, such limited purposes as you have pointed to, do you consider that experiments are necessary?—I do.

19. Are the experiments that you refer to always very painful?—No; I believe that most of the experiments may be conducted with very little expense of pain to the animal.

20. During the course of your experience anæsthetics have been introduced?—Yes.

21. Have they made a great difference in the degree of pain to which a humane experimenter, such as you speak of, would subject animals?—A very great difference indeed.

22. Are the great majority of experiments such as can be rendered altogether painless?—I think so. There are some experiments in which the manifestation of pain is the very test of the matter in question, and these cannot therefore be rendered painless.

23. But the great majority of experiments can, can they not, be rendered entirely painless?—Very nearly, if not entirely, painless.

24. There are some experiments, are there not, in which, though they cannot be rendered entirely painless, yet the pain can be so much mitigated as that only a small portion of the experiment shall be painful?—I believe that to be the case with most of the experiments.

25. With regard to those of which, as you say,

---

* Appendix III., § 1.

Sir T. Watson, Bart., M.D.

5 July 1875.

pain is the test, do you think it is justifiable to subject an animal to lingering pain ?—Not to lingering pain that can be avoided.

26. But is lingering pain ever justifiable ?—No, I think not.

27. Do you think that the eminent persons who are at the head of the two branches of the medical profession would be as much disposed to promote humanity as any other eminent persons in the country ?—I may venture to say that I think they would be as entirely desirous of mitigating pain as any other persons could be.

28. If then what you consider abuses prevail, and it should appear that by reasonable measures those abuses could be prevented, do you think that the Crown and Parliament might look for the support of those eminent persons in carrying those measures ?—I am quite prepared to believe that they might look confidently for such support.

29. Would you say that any experiment that can be performed under anæsthetics ought certainly to be so performed ?—Yes.

30. And that to neglect to entirely destroy, or greatly to diminish, the pain of even a necessary experiment was an abuse which ought to be repressed ?—Yes, I quite think that.

31. You have been for many years, I think 50 years, in the medical profession ?—Very nearly, within two or three months.

32. Having attained to the eminence which I will not ask you to describe, and which we know without its being described, may I ask you whether you yourself have ever been a practiser of these experiments ?—No, I have never been a practiser, nor can I say that I have ever seen one of the experiments.

33. Then we may take it that, although you have stated it to be necessary in some cases and for some purposes that these experiments should be performed, yet a man may attain to the degree of eminence to which you have attained without ever having seen any of them ?—Certainly I do not remember ever to have seen an experiment on animals at all.

34. Nevertheless, you do not think it would be possible that we should have arrived at our present state of medical and surgical knowledge without some such experiments having been made ?—I think we could not have reached our present surgical or medical knowledge without such experiments.

35. Will you have the kindness to give us some illustrations of that opinion ?—It is difficult sometimes to adduce the link which connects the experiments with the future results, but I may say that the discovery of the circulation of the blood by Harvey is an instance in point; if the circulation of the blood had never been discovered (and its discovery was aided and perfected by innumerable vivisections, in the strict meaning of that word, made by Harvey himself) we could never have ascertained or learnt either the surgical or the medical cure of aneurisms, for example, which would infallibly without such cure destroy human life, and produce much human suffering. Harvey himself dwells in anticipation upon the therapeutic fruits of his great discovery. He speaks of having got rid of a large and dangerous tumour by cutting off the supply of blood by tying the little artery which fed that tumour. That is one instance. And so again I should say with regard to the discoveries resulting from the experiments made by Sir Charles Bell and Doctor Marshall Hall upon the nervous system, they have enabled us to direct our therapeutic influences, the influences of drugs (which have been ascertained in far other ways), so as to soothe pain, and to diminish very much the danger to life of many very painful diseases. So again (as I have seen somewhere remarked, and I think very much to the purpose) there were experiments on living animals by the late Doctor Hope, which enabled him to ascertain the causes of certain morbid sounds of the heart; and thereby, knowing those causes, to address to persons who presented those sounds the proper method of appeasing their sufferings, and of promoting, if possible, their recovery. These are instances which suggest themselves at once to me; but there must be innumerable other cases in which the discoveries made by scientific inquirers, through experiments on animals, have been conducive to human comfort, and to the prolongation of human life.

35*a*. (*Lord Winmarleigh.*) Did Harvey ever state the animals on which he made these experiments ?—Yes; and they were very numerous.

35*b*. And the discoveries as they were made by each successive experiment ?—I do not know that that is specified minutely in his works; but he states that he examined the double hearts of vertebrate animals, and the single hearts of many of the lower animals, snakes, molluscs, and so on, snails and beetles, and other creatures.

35*c*. Would it have been possible to make experiments of that kind without the use of anæsthetics; I mean without pain ?—No, not without pain, for at that time anæsthetics were not discovered.

35*d*. (*Chairman.*) But now anæsthetics would enable you to perform some or perhaps all of those experiments while the animal was in a state of unconsciousness ?—Yes, I think many of them certainly.

35*e*. Are experiments upon animals resorted to for the purposes of medico-legal investigation ?—Yes, I believe they are; to investigate the operation of poisons, for instance.

35*f*. When new drugs and supposed remedies are discovered, is the effect of those drugs and those supposed remedies tried in the first instance upon those animals ?—I do not know whether they are much tried in that way; but I confess I should not have much confidence in any results from such trials, because it is well known that the effects of the same drug are often very different indeed upon the human subject and upon the animal.

35*g*. It would be therefore quite possible that a painful experiment or series of experiments might be tried, and the result, so far as the human subject is concerned, might be worthless or misleading after all ?—Yes, I think so.

35*h*. I think you are not personally much aware, are you, of the extent to which experiments upon animals are carried by persons who are not what you have described as competent persons ?—No, I have no personal knowledge on that subject.

35*i*. If a severe experiment is performed of a complicated character, may it not very often happen that nothing at all is proved by that complicated experiment ?—Certainly.

35*j*. Would you not consider that a great abuse ?—A very great abuse indeed.

36. And one justly to be repressed ?—And one justly to be repressed.

37. Now if experiments are performed by unskilled people, is it not probable that the result will be without any object ?—Most commonly I should think, without any utility.

38. And therefore in any point of view they are to be condemned and repressed ?—Yes.

39. Supposing an experiment to be painful, and the fact which results from the experiment to have been already proved to the satisfaction of the scientific world, does it appear to you to be justifiable to repeat such an experiment ?—I think it would be quite unjustifiable.

40. And that anything of that sort ought to be repressed ?—I think so.

41. Should I be right in summing up the general purport of what you have been so good as to say to us in something like these words, that in your opinion it is not possible altogether to denounce the trying of occasional experiments upon living animals ?—I think it would be very undesirable that all such experiments should be repressed.

42. But admitting that, it is your opinion that, now that anæsthetics have been discovered, the great majority of experiments may be made when the animal is in a state of unconsciousness ?—Yes, I think so.

43. That those experiments which are not entirely painless may, many of them, be rendered comparatively painless by the proper use of anæsthetics ?—Yes.

44. That if, in a very few cases comparatively, pain is the test of the question at issue, at any rate lingering pain is under no circumstances justifiable ?—That is my opinion.

45. And is it your opinion that it is the wish of the most eminent men of the medical profession in both its branches to prevent abuse, and to repress cruelty, as much as possible ?—Yes, decidedly.

46. And that the Crown and Parliament may look for the support of those eminent men in any reasonable measures which they may adopt for that purpose ?—I am confidently of that opinion.

47. (*Lord Winmarleigh.*) You say that there are certain experiments, the test of which is pain. Are there any experiments, except those which are connected with the nerves, in which that is the case ?—Pain presupposes that the nervous system is concerned in the experiment,—pain is felt through the nerves, and through the nervous system only.

48. Do you happen to know what has been the nature of the experiments in those cases ?—Some of the experiments of Sir Charles Bell were of this nature. He wished to ascertain of two branches of a nerve which, if either, ministered to sensation, which, if either, ministered to motion alone; and of course it was necessary that he should produce pain in order to test one part of that experiment. The manifestation of pain by the animal experimented upon would show that the nerve then interfered with was the minister of sensation.

49. We may presume that in those experiments the use of anæsthetics is quite useless, that it would be of no effect ?—They would defeat the object of the experiment.

50. Do you think that those are very material with reference to the application to man ?—They have shed much light upon the nature of many of our diseases, and therefore have thrown a corresponding light upon the method of treating them. Anæsthetics, as we are familiar with them, were not known when Sir Charles Bell's experiments were made.

51. Was it necessary in making those experiments to subject the animals to any lengthened pain, what Lord Cardwell has termed lingering pain ?—No, there was no necessity at all; if he was satisfied that he was dealing with a nerve which ministered to sensation, there was an end of the experiment.

52. You believe then that experiments of that kind may be conducted without lingering pain ?—Without lingering pain.

53. (*Sir John Karslake.*) Are there any cases besides those that you have mentioned in which the use of anæsthetics frustrates the object of the experiment ?—In all those cases where the manifestation of pain constitutes the test of the experiment anæsthetics would interfere with it.

54. I wished to ask you whether any other cases suggest themselves to you, than those which you have last described, in which the use of anæsthetics would frustrate the object of the experiment ?—Not that I know of.

55. Not in the case of administering poison intentionally ?—I should think that the use of anæsthetics might vitiate the results of any trials of poisons upon animals.

56. Probably except in those cases anæsthetics might always be administered, except where the object was to ascertain whether pain was given or not ?—The object, I presume, of administering poison to animals for scientific purposes might be interfered with by the operation of the other poison; for anæsthetics are to a certain extent poisons themselves.

57. (*Lord Winmarleigh.*) But does it follow that because any drug would be poisonous to a dog it would necessarily be poisonous to a man ?—No, not at all.

58. On that account I think it was that you said that you had no great faith in experiments made of the effects of drugs upon animals ?—No, I should not have any faith in such experiments.

Sir T. Watson, Bart., M.D.

5 July 1875.

59. (*Sir John Karslake.*) Still the effect of a particular drug upon animals would be beneficial, would it not, with a view to ascertain what the effect of the drug would be upon animals whose lives you hoped to preserve, in consequence of the use of that experiment ?—I have been looking at the question in the light of the benefit which might be produced to the human race by such experiments.

60. But if you can save pain to a large number of animals by experimenting upon one, would you think it justifiable to do so ?—Certainly, I should.

61. (*Mr. Forster.*) A question that Lord Cardwell asked you was with regard to experiments upon living animals. In your answer did you include such experiments as giving animals a disease in order to watch the operation of that disease ?—I do not think that experiments would ever enable one to learn anything in that way. The experiment of giving diseases to living animals is, I think, justifiable upon certain other views.

62. But when you stated that you yourself had not only never practised these experiments, but had never witnessed them, did that include a statement that you have not witnessed experiments in which animals have had diseases given to them ?—Yes, I have never witnessed experiments of that kind.

63. What anæsthetics would you recommend to be used in the case of experiments upon animals ?—Chloroform is the one of which the efficacy is best understood.

64. (*Mr. Erichsen.*) Although you have never performed any experiments or witnessed them, you have used the results of the experiments of others, have you not, as the basis for the advance of your professional knowledge ?—I have made myself acquainted with the experiments and their results, and have turned them to such use as I could.

65. I mean such experiments as Majendie's on the nerves ?—Yes.

66. I suppose one may also gather from what you have stated that we may look upon a new era as having been introduced in experimentation on animals since the introduction of anæsthetics ?—Yes.

67. And that many of these experiments on the nervous system, which undoubtedly were of a necessarily painful character, such as those of Sir Charles Bell and of Majendie, it would now be useless and indeed cruel to repeat, inasmuch as the results are established ?—Exactly.

68. You look upon them as a decided gain to science, and these experiments need never be repeated ?—I should think it cruel and unjustifiable to repeat them, to determine any point which has already been satisfactorily ascertained.

69. (*Mr. Forster.*) I should imagine, from the answers which you have already given to Lord Cardwell's questions, that you would think it a reprehensible practice to use experiments upon living animals as an illustration in medical teaching, to use them for teaching a class ?—I do.

70. And therefore you would not think that in merely teaching either the principles or the practice of medicine or surgery, there ought to be an illustration by experiments ?—Not of any point which has been already ascertained.

71. But even where it has not been ascertained I should rather gather from your answers that you would say that these experiments ought to be conducted by experts, with a view to obtaining knowledge themselves, rather than as a mode of teaching classes ?—Yes, certainly.

72. (*Mr. Hutton.*) You said that anyone who performed experiments of this kind ought to be a good anatomist, and to have trained assistants. Now would you justify experiments of this kind for the purpose of training surgeons, I mean in order that young men who would not be able otherwise to have the proper command of tying an artery, for instance,

Sir T. Watson, Bart., M.D.

5 July 1875.

should do it on an animal to get their hand in ?—I should doubt myself whether it would be of any service to them.

73. You would think that for that purpose, therefore, it is not justifiable to make these experiments ?—I should think it decidedly unjustifiable.

74. Then you say that the majority of experiments can be rendered entirely painless. Now, is it not true (as I have been told) that on the lower animals the effect of these anæsthetics is so powerful, say on frogs, for instance, that it is hardly possible to administer them ?—That I do not know at all; I have no knowledge on that subject.

75. Can you tell me anything about the particular action of an anæsthetic which is sometimes called curare and sometimes woorari ?—I know it has been said that the woorari poison, which renders the animal quite unable to move its limbs, has been used to veil, and so to conceal from the observers, the pain which the animal nevertheless suffered ; but that any such fraudulent trick has ever been practised by the physiologists of this country I decline to believe.

76. I do not imagine that that is what is usually stated, but that it has been used to keep the animal perfectly motionless. Are you acquainted with this "Handbook for the Physiological Laboratory" which I hold in my hand, edited by Dr. Burdon Sanderson ?—No, I have never seen it.

77. In this handbook it is constantly named as being used, and apparently for the purpose—for instance, in experiments on the arterial system—of preventing the failure of the experiment by the motion of the animal ; but I find the strongest possible evidence in Claude Bernard's books that it has no effect whatever on the nervous system ; that it simply paralyses the motor system ?—If that is all it does, then it does not enhance the animal's sufferings.

78. It simply renders it motionless, and leaves the suffering alone ?—And would facilitate probably the experiment itself.

79. (*Mr. Forster.*) Then you would not consider that it ought ever to be used as an anæsthetic ?—No, if it is not an anæsthetic.

80. (*Mr. Hutton.*) You do not know from your own experience whether it is an anæsthetic or not ?—No, I do not know anything about it, more than that it has the effect that you have described of depriving the animal of the power of motion.

81. (*Chairman.*) In your judgment it is not an anæsthetic, is it ?—I imagine it is not an anæsthetic at all.

82. And to treat it as an anæsthetic is a fraudulent trick in your view ?—It would be.

83. Then, in short, you have described that as a fraudulent trick ?—If it were used merely to deceive bystanders into the belief that there was no pain suffered, I should call it a fraudulent trick ; but it might be used for a much better purpose, namely, to facilitate the aim of the operation.

84. (*Mr. Hutton.*) You were saying that the circulation of the blood had been discovered by Harvey by vivisection. Is it not true that he was led to it by a great many other observations before he verified it in that mode ; that it was a verification rather than a discovery, in fact ?—Yes ; but I think the discovery was rendered perfect by his vivisections.

85–6. Was not the microscopic verification of it in the frog's leg even more perfect ?—He looked at the hearts of very small animals indeed ; slugs and snails, which have a single heart only.

87. Still that was not the only mode in which it could have been verified ; it might have been verified by microscopic research ?—Pardon me for saying that that microscopic research implied in the first instance the cutting open of the animal.

88. Not in the case of a frog's leg, a part of which is transparent, is it not ?—Yes ; but his inquiries related principally to the condition of the heart, and of the great vessels which lie close to the heart.

89. I find that a great many of these experiments are given for histological purposes, for the purpose of studying the cellular tissues, and they take place on the living animal for fear that the process should be changed by death. Now, would you justify experiments of that kind for a remote advantage in the study of the science of histology, that it may lead to some future beneficial discovery ?—I hold the opinion that the experimenter upon animals ought to have some definite object in his mind, the attainment of which would be to the benefit of the human race.

90. That there should be some immediate prospect of alleviating suffering by the experiments, you mean ?—Yes.

91. (*Chairman.*) In short, that the inflicting of pain upon animals is a great evil ?—A great evil.

92. That it cannot be justified unless it be by the direct prospect of some greater good ?—Yes.

93. And that that greater good is not a general roving inquiry, but that it must be, to be justifiable, the discovery of some object directly and greatly beneficial to the human family ?—Yes, or the solving of some doubt.

94. (*Mr. Hutton.*) When you said that you could not justify the infliction of lingering pain, what do you mean by "lingering" ?—Pain which might follow the operation, and might remain after the influence of the anæsthetic had departed.

95. For instance, for two or three weeks ?—Or even for two or three hours ; for any time, I should say, lingering pain which could be avoided should be avoided.

96. But supposing the object is to study an induced disease, it is almost necessarily lingering pain, is it not ?—I do not know that experiments are ever made with that object of studying an induced disease.

97. I understood that with regard to the grouse disease a good many experiments of that kind had been made ?—I am ignorant of them, and cannot pronounce any opinion upon them. Mr. Forster asked a question just now which had relation to the induction of disease.

98. (*Mr. Forster.*) I will give you what I have heard to be an object in experiments—to find out the effect of very minute choleraic poison, to discover whether it was in water, for what you may call medical sanitary purposes ?—As far as I understand the object of inducing disease in experiments upon the lower animals, it seems to be (and if I take the right view of it, it is, in my opinion, a very justifiable object) with a view of discovering the producing causes of certain diseases ; and probably with the discovery of these producing causes, the discovery also of the means of destroying those causes, and therefore of preventing such diseases in future.

99. But that is a process of investigation of which you have no personal knowledge ?—I have no personal knowledge of it.

100. Might I ask you what distinction you would draw between vertebrate and other animals as regards their sensitiveness to pain ?—I do not know at all that there is any difference ; but the reason for having recourse to the lower animals in Harvey's investigations was that he might see what happened with respect to a single heart.

101. But do you yourself imagine that a snail would suffer as much pain as a dog ?—I do not know.

102. You have no opinion about it ?—No settled opinion. There are persons who think that we have some grounds for believing that the inferior animals do not feel so sensitively as the more highly organized.

103. There is a sort of popular notion that a warm-blooded animal feels more than one that is not. Is there any scientific foundation for that opinion ?—I do not know how that can be ascertained. We know what Shakspeare said, but I imagine he was wrong.

104. (*Mr. Hutton.*) Has there been much progress in this kind of investigation during your lifetime ?—If you mean by experiments made on living animals, I think that is true of all those experiments, particularly those which were made with

Sir T. Watson, Bart., M.D.

5 July 1875.

respect to the functions of the nervous system by Sir Charles Bell and by Dr. Marshall Hall.

105. I do not mean good results, but do you think that the practice has largely increased in the profession of studying by this mode?—I do not know.

106. (*Lord Winmarleigh.*) You said that you had no knowledge whatever of the extent to which what you have termed vivisection is carried on in England? —No, I have not; but I am confident that there cannot be many persons in this country who are qualified, or who ought to be allowed, to perform such experiments as are under discussion now.

107. Have you ever considered in your own mind how, supposing some legislative enactment was to be passed, the object of limiting it to competent persons could be best carried out?—I cannot say that I have given much consideration to that subject, but it strikes me that any persons who should prosecute physiological knowledge by experiments on animals, ought to be such persons only as might be licensed by some high authority to do it.

108. You would have no other restriction placed upon them, as to the necessity of having a witness by on behalf of the public?—I have not considered what the precautions should be, but only how the experiments might be licensed or allowed.

109. Would you allow anybody who possessed a license of that kind to perform these experiments at his own discretion?—Yes, I think so, if he were licensed by some high authority, which authority was well advised by some responsible person.

110. What person?—I am thinking of the Inspector of Schools of Anatomy. He is a person who exists now, and who is the adviser, I imagine, of the authority; I do not know of what high authority, whether it is the Home Secretary or not.

111. Would you restrict the issuing of licenses to that one authority, or would you place it in the College of Physicians or Surgeons; or in what central authority would you place the power of issuing them?—I think it should be in some high authority, such as one of the Secretaries of State, properly advised by a responsible officer as to the eligibility of the person who seeks the license.

112. (*Chairman.*) Subject to the usual practice of this country as regards responsibility to Parliament? —I may perhaps be quite wrong and presumptuous in saying so, but it seems to me that this vivisection question is scarcely a fit one for discussion in a popular assembly like the Houses of Parliament. I think it could hardly be debated without giving rise to much misapprehension and prejudice, and angry passionate feelings which had better be avoided altogether.

113. (*Lord Winmarleigh.*) What should be the nature of the authority which the Secretary of State should rely on?—He should rely on the responsible officer to whom I have alluded, such as exists now as Inspector of the Schools of Anatomy, who regulates the supply of subjects for dissection.

114. Is that a very high authority in the medical world?—Yes.

115. Is that a higher authority, for instance, than the President of the College of Surgeons, or the President of the College of Physicians?—I think that it would be a very invidious task for either of those persons to undertake.

116. (*Mr. Erichsen.*) You would have an inspector of physiological laboratories as you now have an inspector of dissecting rooms and schools of anatomy? —Yes; I think that would be a great safeguard; and I think that with such safeguard it might be pretty safely left to the honour and conscience and humanity of the experimenters themselves. I would rather that it should be left in that way than that they should be restrained by the fetters of a statute which might be, perhaps, more easily evaded.

117. (*Mr. Forster.*) You are aware that a great deal of the feeling about this matter in this country arises from the belief, whether well founded or not, that these experiments are tried very frequently on a great number of animals in some places on the continent, do you think that it is more practised by physicians or surgeons or by men of science on the continent than it is in England?—I think so from what I read and hear, but I have no exact knowledge on that subject.

118. (*Chairman.*) When you speak of a license being given, for instance, by the Home Secretary, on proper advice, to anybody to perform an experiment, do you mean that he should become a licensed person for the general performance of experiments, or that he should apply *toties quoties* for a license for each experiment or series of experiments?—I do not think that it should be *toties quoties*, but a general permission.

119. Subject to revocation if it came to be known that there was an instance of abuse?—No doubt.

120. (*Mr. Forster.*) Have you ever considered this alternative: supposing that there was to be legislation instead of licensing particular persons, giving them power to make experiments, that there should be a strengthening of the present Cruelty to Animals Act, so that the *onus probandi* should be thrown on a person who was discovered to be making experiments to prove that he was a fit person, and was doing it with a proper object?—That is a point which I have never considered.

121. You have never considered that alternative to actually licensing persons for the experiments?—No; indeed what I have said with respect to licensing persons has been only in my mind this very morning since a conversation I have had with Sir George Burrows.

The witness withdrew.

Sir George Burrows, Bart., M.D., called in and examined.

Sir G. Burrows, Bart., M.D.

122. (*Chairman.*) You are the President of the Royal College of Physicians?—I have the honour to be so.

123. And late President of the Royal Medical and Chirurgical Society?—I was.

124. And late President of the General Medical Council of the United Kingdom?—I was for five years.

125. Have you had any personal experience of this subject, the trying of experiments upon living animals for scientific purposes?—I have had limited experience. That experience consisted partly of witnessing experiments made by others, and partly in this, that I performed some experiments some years ago myself.

126. Will you state in a tlitle more detail the nature of the experiments?—My experiments were to elucidate the condition of the brain in different forms of death. There having been a considerable discussion in the medical profession for many years as to the condition of the bloodvessels of the brain under different pathological circumstances, these experiments were made by destroying animals, either by strangulation, that is by hanging, or by hæmorrhage, or by poison, to ascertain what was the condition of the bloodvessels of the brain in those different modes of dying, with a view to elucidate the pathology of the different modes of death in human beings; but the animals all died in the experiment. Death was accomplished perhaps in a minute or less.

127. (*Mr. Forster.*) In no case longer than a minute, should you think?—If a small animal dies by hæmorrhage it sometimes takes longer.

128. Would you say that it was in no case five minutes?—No; certainly it was not.

129. What animals were they?—Rabbits principally; sheep sometimes.

130. But the suffering of the animals was not in

r
rrows,
M.D.
—
1875.

any case longer than five minutes, and generally not so long?—Certainly never five minutes; indeed, I should think the suffering was not so long as that, because the mode of death caused cessation of feeling before the animal was absolutely dead.

131. (*Mr. Erichsen.*) Was there more pain than in sticking a pig, or any butcher-like occupation?—Not so much, because there was no division of the integuments.

132. (*Chairman.*) Will you give the Commissioners an idea of the other experiments which you have witnessed?—The other principal experiments that I have witnessed were experiments that were performed some 30 or 40 years ago by Doctor Charles B. Williams and the late Doctor Hope, to determine the cause of the sounds of the heart and its motions. The motions of the heart were pretty well determined by Harvey in his experiments on living animals, but the causes of the sounds resulting from those motions, which since the use of the stethoscope we have been able to hear by applying it to the chests of living animals, were not known till those experiments were performed. It is very well known that on listening on the walls of the chest in a healthy person there are certain sounds; but the causes of those sounds were not understood before these experiments were made; and also it is known that on listening on the walls of the chest there are very strange modifications of these sounds when people are diseased; and the cause of the sounds was not understood. These experiments were performed on living animals, which were rendered insensible before the experiments were commenced, and destroyed after the experiments were completed.

133. How were they rendered insensible?—I think it was worari poison: it was before the time that chloroform was known. I am not sure of all the various substances used, but I know that worari was used, and I believe at the suggestion of the late Sir Benjamin Brodie. The animal was rendered quite insensible, and then the heart was exposed and its movements were seen; and by placing the stethoscope on different parts of the heart we were able to hear the sounds generated in particular parts of the heart; then further experiments were made, while the animal was insensible, by introducing fine curved needles through the walls of the vessels and drawing back the valves which immediately modified the sounds, and gave us sounds perfectly analogous to, if not the same as, the sounds often heard in the human frame when the heart and its valves are diseased; and from that time to this the diagnosis or distinguishing from the sounds of the heart the changes of structure which have gone forward in the valves has become a certainty; whereas before that it was confusion; and in that way great benefit arose to human beings in regard to the treatment of diseases of the heart, and the advice which can be given to them. It is hardly necessary, I think, for me to go more at length into that subject.

134. Then I understand your opinion to be that some experiments are necessary for progress in medical science?—I think they are absolutely necessary for the progress of medical science, and I have myself both seen and performed experiments which, I think, have tended very much indeed to advance medical science, and to the better treatment of certain diseases.

135. Since the period that you have last spoken of great discoveries have been made in anæsthetics?—Very great indeed.

136. Was the poison which you spoke of the use of really an anæsthetic?—It rendered the animal insensible; it made no sign of suffering.

137. It is not considered a genuine anæsthetic, is it?—No, because it is actually a poison; it destroys life.

138. But now that anæsthetics have been discovered these experiments might have been performed without exposing the animals to any suffering at all?—I think entirely. Perhaps I may remind you that with respect to the circulation of the blood, the importance of which discovery will not, I suppose, be underrated, that physiological knowledge could never have been arrived at except by experiments on animals both cold blooded and warm blooded; and very recently an oration was delivered by Doctor Guy, as Harveian orator, in which he recited some of the experiments by which Harvey arrived at the full conviction of the circulation of the blood, and to perform which experiments Charles the First put the animals in the royal parks at the disposal of Doctor Harvey, in order that he might carry out these investigations; and when he had arrived at such a point, that he felt he could demonstrate the thing, Charles the First and his Queen, with the princesses, attended a lecture of Harvey's to witness the circulation of the blood proved upon the living body.

139. Would you recommend that example as one to be followed now?—No, I would not; but I mean that it is nothing new in this country that experiments should be made on living animals for the purpose of the advancement of science.

140. Now anæsthetics having been discovered, and having got to the perfection to which they have now been brought, may most of the experiments which are necessary or useful be employed while the animal is entirely unconscious?—I should think nearly all; some few cannot be, particularly those which relate to the nervous system. If you want to ascertain the function of a particular nerve, if you put the animal into a complete state of anæsthesia you would defeat the purpose of the experiment; but those experiments are most of them not of a serious nature.

141. Take for instance such an experiment as those performed by Sir Charles Bell on the nerves of the face, would that be of a painful nature?—So slightly so that you would hardly think it necessary to put an animal or anyone else in a state of anæsthesia to perform it.

142. If performed on a human being for any object, would you use chloroform?—No. I think the utmost a surgeon would do in such a case would be to direct a little ether spray on the surface to deaden the sensibility; but these experiments of Sir Charles Bell, which have been of such use to us in the treatment of disease, arose in this way. It was known that on the side of the face of animals and of man there is a very ample distribution of nerves; but before Sir Charles Bell's experiment there was confusion as to the functions of particular nerves; and he proved that some were nerves directing the movement, and others were nerves communicating sensation; and others, nerves for the nutrition of certain parts; and being a good anatomist, by making a section half an inch long, he was able to determine whether the nerve was one of motion or of sensation. Very important results have followed from that experiment, inasmuch as we often have to treat people who have paralysis on one side of the face; and we may judge of the severity of the case or the danger to be apprehended, according as it is one nerve, or two nerves, or all the nerves simultaneously affected. A person may have a paralysis on one side of the face, and it is simply a paralysis of the facial nerve which comes out behind the ear, and we can tell the person, "Well, this is a trifling affection; there is some little "pressure on your nerve, which can be easily re- "medied." We go to another person and find the same expression of countenance, but at the same time there is a loss of sensation; and we say, "This is "serious; there is some mischief going on in the "central portions of one hemisphere of the brain; "this is a thing which is attended with danger, and "must be treated on totally different principles." It is experiments of that kind which since Sir Charles Bell's time have directed physicians to the proper treatment of particular forms of paralysis.

143. In this particular form of experiment, had the same thing been done on a human being the pain would be so slight, I understand, that you would not think it necessary to use chloroform?—I am quite sure the pain would not be greater than the prick of a spur on a horse's side, because it is momentary, and done with a very sharp instrument, and there is an end of it.

144. But I understand you to say that the great majority of experiments can be performed under chloroform in such a way as that the animal shall be entirely unconscious ?—Yes ; and in the great majority of those which cannot, the more painful part of the operation can be performed under anæsthetics, and then the remainder carried out.

145. Supposing an experiment to be of a very lingering character, would you think that it was justifiable at all ?—It would depend upon the importance of the object to be attained very much.

146. May I understand that the sentiment of the leading men in the medical profession in both its branches is as likely to be favourable to humanity as the sentiment of eminent men in any other department of science ?—Of course it is difficult to form an opinion upon that matter ; but my opinion decidedly is that the members of my own profession, in both branches of it, are naturally as humane and likely to be as humane as any other men.

147. And that they are likely to consider that any inhumanity or any abuse of a practice of this nature is discreditable to the profession, and ought to be put down if possible ?—I think there would be a general condemnation of any abuse of it.

148. And a general disposition to support any reasonable provisions to check abuse ?—Yes ; I think there would be a readiness to assent to any reasonable proposition to check abuse.

149. And that incompetent persons should not be permitted to set themselves to the performance of experiments ? — I think that incompetent persons, persons who have not a thoroughly good knowledge of anatomy and physiology beforehand, ought not to be allowed to undertake those experiments.

150. That that is simple cruelty without any useful purpose whatever ?—By accident a useful purpose might result ; but it is not a justifiable proceeding. Unless a man has prepared himself beforehand by acquiring a very sound knowledge of anatomy and as sound a knowledge of physiology as he can, I do not think he is justified in making experiments on any animal.

151. And that it would be a reasonable thing that the Crown and Parliament should interfere to prevent any practice of that sort on the part of uneducated and incompetent people ?—I think there should be some sort of interference with incompetent and uneducated people attempting experiments on living animals certainly.

152. Have you considered at all any particular mode by which it would be most wise to endeavour to effect that object ?—I think that is by far the most difficult question which you have put to me. It would be extremely hard to say that if scientific men wanted to perform an experiment on a frog or a rabbit, they must immediately go to some authority established by the legislature and ask permission to perform it. I think that that would be an interference with the progress of science, and would be more than would be justifiable in my judgment. On the other hand, I think that in the case of persons who wish to undertake a series of experiments on living animals, or who intended to perform a series of experiments on living animals, it would be quite proper that there should be some controlling and restraining authority ; but I think that an incessant interference, and the necessity for every individual experiment of applying for authority to the Secretary of State or any other authority, would be almost too great an interference with individuals.

153. I think I collect from you first that some experiments on living animals are in your opinion necessary for the progress of science ?—I think there is no doubt of that.

154. And probably for medico-legal investigation ?—I think there is no doubt of that.

155. And you think that, in consequence of certain statements which have come before the public, there is an exaggerated idea prevalent as to the painful nature of the majority of experiments ?—I do think from the conversations I have had, not with scientific people, but with humane people whose feelings are very acute and who are horrified at the idea of cruelty being practised on dumb animals, that they have an idea that the practice of what is called vivisection is carried out to a much greater extent than it really is ; and I believe that many of those persons, who are persons of strong feelings and very humane in their nature, are under an impression that vivisection means the dissection of living animals ; they think that these operations upon the living body are somewhat analogous to that of dissection on the dead body. I am sure that there is a confusion in their minds on the subject, and it ought to be made well known to the public that really what is called vivisection very often is something so trifling that, as your Lordship put it to me just now, you would never think of employing an anæsthetic to perform it ; and also experiments that are performed on animals very often do not imply any cutting at all ; no instrument is used ; you have to administer a medicine or a poison to see what the effects are. Now we know pretty well what the effects of strychnine on an animal are ; but an experiment might be performed to show the effects of strychnine on the nervous system or the muscular system, and there is no cutting. So also an experiment might be performed to see the effect of inoculation ; you might inoculate an animal ; if you inoculated a human being to prevent some particular disease you would hardly call that vivisection.

156. But you are probably aware that in some cases at least, either here or abroad, very severe, and what would by most people be called extremely cruel, operations have been performed on animals ?—I am quite aware of that.

157. And those are what you have hitherto referred to, when you have spoken of the abuses ?—I think there have been great abuses in the performance of operations and experiments on living animals.

158. And that those abuses ought to be restrained ?—I do think so.

159. And that the knowledge of those abuses is what has led to the strong feeling which is entertained by a portion at least of the public on the subject ?—Partly that, and partly, I think, ignorance of the subject.

160. And that the majority of experiments could be performed while the animal was entirely unconscious, and that they ought to be so performed ?—I think that they could be so performed, and ought to be so performed.

161. And that the highest scientific men would be quite as much disposed to arrive at that conclusion as any other portion of the public ?—I do not know whether they would as readily as any other portion of the public, because they see the difficulties in the way. Other people are governed simply by sentiment, and wish to avoid pain to dumb animals, but they do not know the difficulties in the way ; whereas scientific men see that there are great difficulties in the way.

162. But if the great majority of experiments can be performed while the animal is entirely unconscious, what is a great difficulty in securing that that shall be done in such cases ?—That is to say, what is the difficulty of securing that the operation is performed under anæsthetics. I think I have said already that there are a certain class of experiments which cannot be performed under anæsthetics, but that the great majority of them most undoubtedly can be performed under anæsthetics.

163. If that be so, is it not reasonable that any experiments which must inflict great pain should be performed under some special sanction ?—Yes ; it is quite reasonable and proper.

164. Although you think it may be difficult to arrive at a conclusion as to what that special sanction should be ?—There is the difficulty, I think.

165. Have you thought about the subject at all, so as to be able to assist us on that point ?—I think that, whatever controlling authority there may be, it should

Sir G. Burrows, Bart., M.D.

5 July 1875.

be one that would, to a certain extent at any rate, command the respect and confidence of scientific men. I do not think, for example, that the Attorney-General prosecuting, or the action of the Home Secretary, would alone be sufficient, unless the scientific world could be assured that that legal functionary or that minister of state had been properly advised upon the matter. I think that the scientific world would think it a great hardship if they were to be restrained, unless they were restrained by some one who really had a competent knowledge to enable him to know when he ought to exercise that authority.

166. But supposing that that legal functionary, or minister of state, acted under responsibility and with the highest professional advice, you would consider that that was a proper sanction ?—Yes; but I do not know whether there would be any security that he would have competent scientific advice; that is the danger. You see if you take a gentleman occupying the high position of a Secretary of State for the Home Department, there is nobody, so far as I know, in that office to advise him on such subjects at all; and he would naturally, when a question of this nature came before him, go home and send for his general practitioner, Mr. A, B, or C, and ask him what he thought about the matter. I should not say that that was competent advice.

167. You would think it ought to be responsible advice ?—Yes; I think there should be some person to advise him, having functions somewhat analogous to the Inspector of Anatomy. Anatomy in this country was at one time conducted in the most scandalous and disgusting manner in every way; and now the anatomical schools are conducted in a totally different way. There are certain places licensed for dissection, and the Inspector of Anatomy has the power of going in at any time to see that everything is conducted with propriety, and to examine the book in which a record of all the bodies is entered, and the circumstances where they come from, and so on, and also that the remains of the bodies are properly interred; and it seems to me that there might be either the Inspector of Anatomy, or an officer having analogous functions, with reference to these physiological experiments; somebody who would be called upon to investigate the matter, to send in a written report; and upon which written report the Secretary of State, or other authority, would act. Then if the action be called in question, there would be a document from a person competent to give information on the subject, to satisfy the scientific world that there was nothing arbitrary or captious in the proceeding. I think that if the legislation proposed were that the Secretary of State for the Home Department should not have the power of interdicting or allowing these things without the scientific world and the world at large knowing that he had taken pains to obtain advice, and that advice could be brought forward if called for, that would be much more satisfactory than leaving it to the *ipse dixit* of the Secretary of State.

168. There were difficulties formerly in regard to anatomy, I understand you ?—Very great difficulties.

169. And you say that the practice was in some cases scandalous ?—Yes.

170. Which has been remedied ?—Yes, by the Anatomy Act.

171. The same general course of proceeding which has overcome the difficulties in regard to anatomy is what you would suggest with regard to the difficulties of the present case ?—I think they might be overcome in that way. What I think is that there should be some kind of competent authority, such an one as would command respect, so that one could say, "This is not "a captious system, but it is founded on proper "information, and which could be produced to the "scientific world," and so that the Secretary of State could say, "This is the information which I have "before me, and I exercise my judgment upon this "information."

172. So long as it was a responsible opinion founded upon proper professional warrant and information, you would see no objection to the interference of the Secretary of State ?—I think not. But another thing strikes me. Of course, in a country like our own, where the Government changes from time to time, and the men who occupy high offices pass through them, one first and then another, one man may have prejudices one way, and another another; and if the advance of physiology is to be dependent upon the feelings or opinions of an individual, I think that would be very unfortunate. I think that there should be some officer or person appointed, who is a fit person, a good anatomist and a physiologist himself, and who is competent to form an opinion, and that his opinion should be given to the Secretary of State; and that this individual should be a permanent officer as long as he conducted himself properly; *quamdiu se bene gesserit;* but I think it would never do to leave it to a gentleman occupying the position of Secretary of State unless he had good information to guide him.

173. (*Sir John Karslake.*) I understand that you would rather suggest that a person who wished to carry out these experiments should make application to the Secretary of State, who should refer his application at once to such an officer as you have mentioned. Would that be the process ?—There might be certain places licensed for the performance of physiological experiments, as you have certain places licensed for dissection; and then of course the place would be sanctioned by authority, and experiments would be performed there because it was licensed to have experiments performed there. I do not mean to say that that is the best way. I do not presume to say that I have thought the matter out enough.

174. I rather understood you to say that the cases in which vivisection ought to be practised are comparatively rare ?—Yes.

175. That wherever the thing has been clearly established already, you would never have vivisection performed merely for the purpose of confirming what has been satisfactorily established ?—That is my opinion; that where experiments have been performed already, or a point of physiology has been ascertained, the experiments should not be permitted. I do not think that an experiment should be repeated over and over again in our medical schools for illustrating what is already established.

176. But I also understood you to say that the person who does make these experiments should be a practised anatomist, and should not be allowed to do it till he has a considerable degree of scientific skill ? —I think he ought to be a man who has considerable scientific skill and knowledge of those branches of science, anatomy and physiology in particular.

177. Would not that rather point to the person, who was licensed as you suggest, applying on behalf of himself personally rather than on behalf of any particular building in which these experiments should be sanctioned ?—I do not mean to say that it might not be right and proper that an individual of that competent nature should be allowed to apply for leave to perform experiments irrespective of their being performed at a particular place.

178. Then you think that leave might be given to allow experiments of this description to be performed at a particular place subject to the penalty of the withdrawal of the license on improper experiments being performed, or on their being improperly performed there ?—Yes, it is a difficult question; but I can conceive a case to arise where a surgeon or a physician either might wish to do something in which he would like to have his knowledge fortified by an experiment on an animal; and if he were to wait for application, say to the Secretary of State, and the Secretary of State has to refer to his inspector and to get his answer, the patient might die meantime. Such a case might arise; I do not mean to say that it is likely to arise frequently, but if an experiment were deferred till all this correspondence had been gone

through, the circumstances would have passed by which necessitated the experiments, and the person might not have got the benefit which he otherwise would.

179. Whereas in such a case as that a comparatively painless experiment upon an animal might enable the practitioner to determine what course he should adopt with the human patient?—Yes; it might occur with surgery in particular, I think.

180. (*Lord Winmarleigh.*) Have you any knowledge of the extent to which this practice is being carried on in England at the present time?—I have not any accurate knowledge on the subject. I can tell your Lordship that I was for 30 years the physician and the principal medical teacher of one of the largest medical schools of this metropolis, that attached to St. Bartholomew's Hospital, and the number of experiments made in those 30 years were very few indeed.

181. You have no knowledge of what is going on in the different large towns of England at the present time?—No, nothing except what I know from occasional reading of the newspapers and scientific journals.

182. Could you state to the Commission briefly what are the chief benefits that have been derived to the human race from the experiments which have been made within your own time by these means?—I do not think that I could give you a sufficient account of them by merely answering the question in that way.

183. For instance, you mentioned just now the benefits derived as regards the affections of the heart?—Yes, those are some of the principal ones that have come within my range as a physician.

184. You could not mention any others of equal importance?—Yes; the experiments that were performed by Doctor Marshall Hall some years ago upon the nervous system, by which he established very important principles as to the functions of different parts of the spinal chord independent of the brain itself, showing that there are certain functions residing in the spinal chord which were not known to exist before, commonly called the reflex functions of the spinal chord.

185. And are the spinal chords of animals affected by the same things as those of human beings?—Yes, of mammalia; I am speaking of the reflex action of the spinal chord as pointed out by the experiments of Doctor Marshall Hall and others.

186. The experiment made with reference to the nerves I believe cannot be made without causing pain to the animal?—Those experiments would not occasion very great pain, because in some of those experiments there would be the division of the spinal chord itself, by which all parts of the body below the division would be without sensation of any kind, and the experiment would show you that although all communication between the brain and the distant parts of the body was severed, yet there were peculiar functions performed in these distant parts which you would have fancied beforehand were dependent on the brain; showing that they are altogether independent of the brain, and are dependent on a principle resident in the spinal chord itself, quite independent of the brain. For example, a man may be lying in his bed and apparently motionless, supposed to be paralysed, say a soldier or sailor; and the nurse in charge would have told the surgeon in days gone by, and might do so now, "That fellow is deceiving us; I have seen him move his legs in the night." "Is that the case?" "Yes, I can swear to it, and you can go to him yourself and ask him to move his legs." He says that he cannot do so. "You must try, sir;" and you uncover the bedclothes and just touch the fellow's foot with a feather, and he will draw his legs up, and not know that he is doing it. That is from an independent function in the spinal chord. He himself would be quite unconscious of the movement and have no power or control over it at all. Those experiments of Dr. Marshall Hall and others point out to us an explanation of forms of disease which we did not understand before.

187. And of which the medical profession have taken advantage for the benefit of the human race?—Very much so indeed. No doubt we should have believed before those experiments that there must be some disease in the brain in that case, whereas we know now in many of these cases that the disease is not in the brain at all, but in the spinal chord.

188. Have any great benefits been obtained with regard to the liver through discoveries made by means of experiments?—There have been very important discoveries indeed. There are the experiments of the French physiologist, Claude Bernard, by which he established that the functions of the liver were not, as commonly supposed, simply for the secretion of bile, but that another very important function was performed by the liver, the elimination or elaboration of a principle which becomes the saccharine principle of the blood.

189. That was discovered by means of animals ,and could not have been discovered by any experiments on the human frame; is that so?—It never entered into the thoughts of men before that the liver had such a function as that; and I do not know how they would have arrived at such a conclusion without such experiments.

190. Do you say that without destroying animal life you could not have got that knowledge?—I will not go so far as that, but I cannot conceive how you would have got it in any other way.

191. Do you believe that in the long run the chief experiments that have been made upon these animals have been such as could not have been performed upon the human frame without danger to life; I mean those experiments now so much complained of as having been made on animals; do you believe, speaking of them generally, that they are experiments which could not have been made safely on the human race?—They could not; they would involve the death of the human individual. These experiments of Claude Bernard on the liver involved the death of the animal.

192. Do you think that there are any of these experiments which cannot be made without inflicting pain on the animal?—Under our present knowledge of anæsthetics they can generally be performed without creating pain.

193. You think, without exception?—I think so, excepting those upon the nervous system, and a large portion of those, for example, when you want to get down to the spinal chord of an animal to divide it, the animal is partially under an anæsthetic whilst it is being done, and you see the result of the experiment afterwards. The most painful part of the experiment would be cutting down to the part, and all that could be avoided by putting that animal in a state of anæsthesia while that part of the experiment is made.

194. But the test of some of the experiments is the pain they cause, is it not?—Yes, some on the nervous system, not all.

195. It would not be a successful experiment in some cases, unless it showed what pain was caused?—That experiment of the division of the spinal chord itself puts an end to all pain in the part; then, as to the subsequent experiments on the parts which are below the section of the chord, they are absolutely without feeling.

196. Do you believe that there are any means of conducting the experiments on the nervous system without causing pain to the animal; I mean the general nervous system?—That is a very difficult question to answer. There are some parts of the nervous system which might be operated on without causing pain.

197. But you could not apply that without an exception?—No; but the fact is I am not what may be called a scientific physiologist, and therefore it must be understood that I am not well informed on all these points.

Sir G. Burrows, Bart., M.D.

5 July 1875.

198. (*Mr. Forster.*) You, I think, would limit these experiments, as I gather from your answer, to cases in which the experimenter was a man of real scientific knowledge, and likely to be able to arrive at some knowledge which would be of use to the profession?—I think ignorant persons, persons who have not obtained a high knowledge of anatomy and physiology, certainly ought not to be allowed to perform these experiments.

199. Would you or would you not think it desirable to illustrate medical teaching in classes by experiments on living animals?—I think it would be very improper to do so.

200. And in the same way you would think it improper that young men teaching themselves, as it were, should go into a course of these experiments?—I think, unless their knowledge has been already ascertained, and they are clearly men competent to do it, they ought not to be allowed to do it. But I can conceive a young man, not a teacher of physiology, having a great love and taste for the science, and having a thorough acquaintance with all that has been done hitherto, believing that he could advance knowledge by experiments; and I can fancy his performing experiments which might lead to important results.

201. Would you encourage young students to do that?—No, certainly not; I should deter them.

202. You would draw a line between this kind of experiment and other kinds of experiments, because you would say, generally speaking, I suppose, to a young man who was studying any branch of science, physics or chemistry, that the more experiments he tried the better?—Yes; certainly.

203. But in this case you would think it very desirable that he should be limited?—I would.

204. Do you think that the medical students in the kingdom are much in the habit of trying these experiments?—No, I do not think so.

205. The impression exists on the minds of some persons, who take great interest in the matter, that they are in the habit of doing so, and there are two or three facts that induce them to think that. One is the fact that this book, a book entitled "Handbook for the Physiological Laboratory," edited by J. Burdon Sanderson, seems to encourage these experiments just as much as any other experiments. Are you aware of the book?—I know of its existence, but I cannot say that I have read it.

206. Is it a book which is considered a sort of handbook to the profession?—It is very new; I think the very first edition of it cannot be above a year old. It certainly is a book which has come out within the last 12 months.

207. I find at the beginning of the preface these words, "This book is intended for beginners in "physiological work. It is a book of methods, not "a compendium of the science of physiology, and "consequently claims a place rather in the laboratory "than in the study. But although designed for "workers, the authors believe that it will be found "not the less useful to those who desire to inform "themselves by reading as to the extent to which the "science is based on experiment, and as to the nature "of the experiments which chiefly deserve to be "regarded as fundamental." I think one would gather from that that the experiments here mentioned are rather mentioned with a view to their being made?—I do not know whether that is a correct inference or not; but I should certainly think it means to imply that these experiments were carried on more extensively than I am aware of; but I should think it did not mean that it was for students, but rather for those who were teaching physiology.

208. I have not read the book, but here is an experiment upon rabbits (*handing the book to the witness*); it is headed "Excitation and section of the spinal chord "in the rabbit;" is that what you have been describing in your answer to Lord Winmarleigh?—No, not at all.

209. Now is not that an experiment that without anæsthetics would be both painful and lingering?—I should think both painful and lingering.

210. Would it be a successful experiment with the use of anæsthetics?—I do not feel myself competent to say; it is a long detailed experiment.

211. You would not in your position in the profession recommend to young men to practise these experiments on living animals by themselves, or recommend these experiments to be part of medical teaching?—I should recommend them not, and should take steps to prevent their doing it.

212. I observe in this book that has been lately published that an experiment is represented as being tried under the influence of curare; is that really an anæsthetic or not?—It is, I suppose, the same as worari, is it not? It is only a different way of spelling it. I have seen animals under the influence of it, and they seem to be insensible; I cannot say more.

213. Supposing that it be not pretty well proved that curare is an anæsthetic, you would, I imagine, be strongly opposed to an animal being put under its influence?—I should certainly.

214. (*Mr. Erichsen.*) You were speaking of the advance that had been made in medicine in respect of diseases of the heart and the nervous system during your practical experience; could that advance have been arrived at by any mere clinical or pathological observation, or in any way except through the means of experimentation upon living animals?—No advance had ever been made up to this time; and I do not, in looking back now, see how it could have been done. I would not absolutely say that if they had taken a very large number of instances and very carefully tabulated them, they might not at the end of a number of years been able to arrive at approximate results; but I think it doubtful whether any one person could have done so.

215. Up to the time that Sir Charles Bell made his experiments on the nerves of the face it was the common practice of surgeons to divide the facial nerve for the cure of neuralgia, tic doloreux; whereas it exercises, and was proved by Sir Charles Bell to exercise, no influence over sensation, and its division consequently for the relief of pain was a useless operation?—Yes.

216. We have spoken hitherto chiefly of painful experiments; but are there not a great many experiments that have also been practised that do not occasion any very material suffering? For instance, with regard to the induction of disease, do you think that such experiments as endeavouring to ascertain how tubercle is developed in animals, by placing them in certain unfavourable hygienic conditions, would be a proper experiment to perform in order to elucidate the causes of tubercular disease?—I think quite justifiable.

217. And it would not be painful?—If the disease were induced, of course there would be all the inconvenience of that to the animal.

218. But domestic animals die very largely of that disease?—Yes.

219. Then there are also a number of experiments that have been performed for medico-legal purposes, with reference to testing the effect of drug remedies and poisons. Do you think that such experimentation is proper in order to test the quality of a new remedy before it is applied to man. Supposing a new alkaloid, for instance, is discovered, if it is desirable to test the effect of that alkaloid, would it be right to test it at once upon a man or upon one of the lower animals?—I think such an experiment on an animal would be quite justifiable.

220. Those experiments have been of use?—Very great use indeed.

221. (*Mr. Hutton.*) Have you not rather underestimated Sir Charles Bell's own view of the painful nature of his experiments, because I notice in a letter of his to his brother in 1822 he says, "I shall be "writing a third paper on the nerves, but I cannot "proceed without making some experiments which "are so unpleasant to make that I defer them. You

Sir G. Burrows, Bart., M.D.

5 July 1875.

" may think me silly, but I cannot perfectly convince " myself that I am authorised in nature or religion to " do these cruelties; . . . . and yet what are my " experiments in comparison with those that are " daily done, and are done daily for nothing?" That is a passage in regard to those particular experiments that you spoke of as almost painless, I think?—Well, there were some other experiments of Sir Charles Bell's that were much more painful than those I have alluded to; but with respect to that passage, all I would say is that I think it redounds very much to the honour of the man, exceedingly so; and although he was prepared to make physiological experiments for the advancement of science, his good feeling made him shrink from that which he thought it afterwards his duty to do.

222. Do not you think that people are beginning to underrate much more than they used to do the painfulness of these experiments, while the experiments themselves are multiplying in number? That passage which I have read is dated in 1822, and he speaks there of the experiments as large in number, whereas they are much more common now than at that time.—I think he refers there to experiments going on at that time in Paris by Majendie, who was rather regardless, perhaps, of the sufferings of his victims; I think Sir Charles Bell adverted to that probably.

223. Do not you think in our English schools this particular method has grown of late years; that this method is considered a more powerful scientific method than it was thought to be in Sir Charles Bell's time?—Yes.

224. And therefore its use has been multiplied?—It has been resorted to more frequently.

225. In fact the practice now is very much more extended in medical schools than it was 40 or 30 years ago, and in physiological laboratories?—I think it is.

226. You were speaking of your own experience in St. Bartholomew's, that during your 30 years there there were very few experiments of that kind, if any?—Very few. I will not say none, because it was while I was there that I tried the experiments which I adverted to, and I remember the effects of the experiments which Mr. Erichsen alluded to.

227. Are you aware of the experiments of Doctor Legg, for instance, on the biliary fistula of cats?—I have been 10 years away from Bartholomew's, and therefore I think you had better ascertain that from some other source.

228. When you say that by far the majority of these experiments might be conducted by anæsthetics, is it not true that in the lower animals they are so powerful that you cannot give them,—to frogs for instance,—unless it be this doubtful anæsthetic, this curare?—I am not able to give an opinion.

229. A large number of experiments are made upon frogs, and if they cannot be conducted with anæsthetics, then the majority of experiments cannot be, I suppose?—I am not conversant with physiological questions sufficiently to answer that.

230. You would say that the experimental method is growing, as compared with other methods, in the medical schools?—In physiological laboratories, not in the medical schools.

231. (*Mr. Forster.*) When you speak of medical schools do you mean such as that at St. Bartholomew's?—Yes.

232. (*Mr. Hutton.*) I thought that a medical school was thought of little value unless a physiological laboratory was annexed to it?—No doubt physiology is now practically taught as it was not before taught.

233. Would you say that the legitimate object of these new experiments is new knowledge or new remedies; would you put the pure scientific object as the proper object of these experiments, or would you say that you must have in view some clear alleviation of human or animal pain as the object of the experiments?—It is knowledge in the first instance that is the object of the experiments; and that knowledge having been obtained, it leads most materially to the alleviation of human suffering.

234. You would make it an experimental science in the same sense in which chemistry or mineralogy is an experimental science, and would say that experiments, wherever they seemed to be leading to fresh knowledge, might be pursued simply on the ground that the experimenter sees a glimpse of some fresh light and knowledge which he can get by experiments; would you go as far as that?—No; I think it is going almost too far to say that I do not think experiments are to be performed merely where persons see a glimmering of knowledge to be obtained.

235. But a good many that I have seen described seem to have been of that character, that they opened more questions than they solved, so that I wanted to know whether you took the scientific view of these things, or the view that to sanction such experiments you must have a real remedial agency in prospect?—I think myself that the advance of knowledge would be a sufficient object, if there is good reason to believe that knowledge would be greatly advanced by the experiment, provided it is done with proper precautions.

236. It is hardly ever possible to know whether knowledge will be advanced; in all experimental sciences it is the mistakes that bring as much knowledge as the things that are done with a real clear anticipation of what is going to happen. Those which give a result that was not expected are quite as instructive as those which give a result that was expected?—It may often happen that there are discordant opinions on a particular point of physiology or pathology, and that discordance very likely might be removed by a well-arranged and well-performed experiment; the two parties would then get much sooner to the truth, and that discordance would disappear then.

237. But you would limit it by saying that there must be some immediate prospect of a beneficial result in view; that it is not justifiable to look upon painful experiments as the agency of mere experimental science?—With respect to physiology alone or to medicine at large do you mean?

238. I want to know with regard to either?—I think myself that where there is a sufficient reason to hope and to expect that knowledge would be greatly advanced, without seeing what ulterior benefits are to result from that knowledge, the experiment should be performed.

239. You put it on the same ground as the other experimental sciences with the limitation that you would never give pain where you could help it?—Not exactly on the same ground, because it is immaterial when a man takes chemical ingredients whether he mixes them in a certain way or not; but that is not the case with living animals; in their case the man must have a good object and a reasonable prospect of advancing knowledge; whereas a chemist might try all sorts of combinations without any definite object at all.

240. You mean that for pure curiosity it would not be allowable to make these experiments?—Just so.

241. But that whenever you had a real scientific result in view it would be allowable?—I think so.

242. Whether it led to a remedial agency or not?—If the man had a scientific result in prospect I think it would be justifiable, provided it were performed under proper conditions.

243. Here is an experiment which a medical man describes, and which he saw. He says, "Several " frogs were put under the influence of 'woorara' or " 'droorara' poison, which, while it deprives the poor " creatures of the least power of movement, leaves " sensibility to pain unimpaired; some think the latter " is even increased. They were then slit open in " such a way as not to kill them, and a delicate trans- " parent tissue containing bloodvessels partially " dragged out from the inside of their bodies, and " placed under a microscope. They were left thus for " two hours." That was to study the tissues; and a great many of the experiments in this handbook are to study the changes in the tissues which take place, for which it is necessary that the animal should still be alive. That is a purely scientific purpose, but it

Sir G. Burrows, Bart., M.D.

5 July 1875.

does not immediately lead to any remedial agency. Would you justify that kind of experiment?—I do not know. Unless I had time to consider the matter, and saw the experiments and knew all the conditions, I should not like to express an opinion on it.

244. (*Chairman.*) I understand you to say that Harvey's discovery has been followed by great remedial consequences?—No doubt.

245. But those remedial consequences were not foreseen by Harvey at the time when he made the experiments which resulted in his great discovery?—No, they could not be foreseen. At the time when Harvey made his experiments there was great confusion in respect to the course of the blood, and his experiments were made and settled that question.

246. His experiments were made for the purpose of making the discovery, which he did make, of the circulation of the blood?—Yes.

247. It was at the moment a mere scientific discovery?—A mere scientific discovery.

248. But it has been followed since by great remedial consequences, which were not foreseen by Harvey at the time that he made the experiment?—Exactly so.

249. The opinion which you have been so good as to give us I have understood to be to this effect, that experiments in general can be made under proper anæsthetics while the animal is entirely unconscious and incapable of suffering?—As a general rule that is so.

250. And you have reprehended very much any person who makes an experiment of that sort otherwise than under complete anæsthesia?—I reprehend its being done in any other way, if it can be done under complete anæsthesia.

251. Then you have said that you think experiments which cannot be made wholly painless can yet be made principally painless by the proper application of anæsthetics?—Yes, I have said so, and I hold to that opinion.

252. Then you have said that there may be a limited and a very limited number of experiments left, which will cause a degree of pain to the animal, which it is painful to the operator and to everybody else to contemplate?—No doubt that is the unfortunate result.

253. And you have said, with reference to those experiments, that you think there should be in every case a special sanction; and with regard to that special sanction you have rather pointed to the experience in regard to anatomy as a guide to the remedies which you think it might be suitable for us to recommend to the Crown and Parliament?—Yes, I do think so.

254. That is a correct description of your general view upon the subject?—Yes, it is. With respect to the last part of the summary of my views which you gave, I should say, that whoever is the authority should be guided by somebody who has full and sufficient knowledge of anatomy and physiology, so as to give really sound advice, and who is responsible for that advice.

255. (*Lord Winmarleigh.*) Should he not also have a general knowledge of the character of the person? Supposing, for instance, that a Secretary of State (if he was the person to give the authority) should be desired by some person fit to give him that advice, should not that man also have a knowledge of the general profession?—Yes; I think he ought to have a knowledge of the individual, what his character is, and his position, and what his attainments are.

256. It would not be necessary that he should have a knowledge of physiology?—No, but that he should know his character and standing and position.

257. (*Chairman.*) Did not Majendie come once to this country?—Yes, I believe he did.

258. And was not he almost driven from it by the feeling which his experiments created?—I cannot be sure. I think that you will get that information much better from other sources than from me.

259. (*Sir John Karslake.*) Do you think that the administration of new drugs as a poison to animals is useful with a view to ascertain their effect on the human subject?—It has been useful on different occasions, no doubt.

260. Sir Thomas Watson seemed rather to think that it was not, as I understood him; but in your experience it has been useful in certain cases?—I think it has, certainly.

261. So that by bringing science to bear you think it would be justifiable to use poisons on animals to discover the symptoms produced when they are taken by human beings?—The information obtained would be imperfect, but it would be useful as enabling us to avoid doing injury. If a new alkaloid was discovered, and it was reported to have certain properties, it would be desirable to have it administered to an animal to see its effects before it was administered to a man.

The witness withdrew.

Sir James Paget, Bart., called in and examined.

Sir J. Paget, Bart.

262. (*Chairman.*) Besides your position in the Royal College of Surgeons, you are, I think, President of the Medical and Chirurgical Society?—Yes.

263. And your attention has been very much directed to the subject which is now being inquired into by this Commission?—Yes.

264. You have prepared, I think, or have taken part with Mr. Huxley and Mr. Darwin and others in preparing, a petition which was intended to be presented to Parliament on the proposal of any Bill upon this subject?—Yes.

265. And that petition adopted certain resolutions?—Yes.

266. Which resolutions were passed at a meeting of the British Association at Edinburgh?—Yes; in 1871.

267. Those resolutions were these:—"(I.) No experiment which can be performed under the influence of an anæsthetic ought to be done without it. (II.) No painful experiment is justifiable for the mere purpose of illustrating a law or fact already demonstrated; in other words, experimentation without the employment of anæsthetics is not a fitting exhibition for teaching purposes. (III.) Whenever, for the investigation of new truth, it is necessary to make a painful experiment, every effort should be made to ensure success, in order that the sufferings inflicted may not be wasted. For this reason, no painful experiment ought to be performed by an unskilled person, with insufficient instruments and assistants, or in places not suitable to the purpose; that is to say, anywhere except in physiological and pathological laboratories under proper regulations. (IV.) In the scientific preparation for veterinary practice, operations ought not to be performed upon living animals for the mere purpose of obtaining greater operative dexterity."—Yes.

268. Those resolutions, having been agreed to by the British Association, have received your entire approval?—Yes.

269. And that of eminent scientific persons like Mr. Darwin and Mr. Huxley?—Yes; the petition was signed by many more: Professor Owen, Sir William Gull, Sir William Jenner, the President of the College of Physicians, the President of the College of Surgeons, and several more leaders in science.

270. So that in any reasonable plan for giving effect to those resolutions, the Crown and Parliament might rely upon the cordial support of the leading scientific men in this country?—Yes.

271. Now, is it your opinion that the question

Sir J. Paget, Bart.

5 July 1875.

whether there shall be an experiment on a living animal is an optional question altogether?—No.

272. What is your view upon that subject?—I think it may be said generally that medical science, being in a state of progress, is continually coming in sight of things which can only be decided by experiments, either upon man or upon some lower animal.

273. Supposing that a patient is brought to you, having received some injury, for instance, which requires your care, you either do know what to do with him or you do not. If you do, you proceed upon knowledge already obtained; but if you do not, there is the necessity of an experiment in his case, is there not?—Yes.

274. And the experiment in his case will be excluded if you have previously obtained complete knowledge of a case of that kind?—Yes.

275. And it is for the purpose of such knowledge that you consider some experiments to be necessary?—Yes.

276. Since you have been in practice anæsthetics have been discovered?—Yes.

277. Do they materially affect the question which we are now considering?—Yes, in so far as they make a large number of experiments possible without the infliction of any pain at all; and those may be experiments of the most important kind.

278. Are a large proportion of the experiments that you would recommend capable of being performed under chloroform? — A very large portion; but there is a class of experiments which are becoming more frequent, and which I think in many respects more necessary, namely, testing the effects of medicines and of poisons, and the production of diseases in animals, for the purpose of studying them more accurately than is possible in men; and in those of course anæsthetics cannot be used during the progress of the disease.

279. Having got the resolutions, which you have approved, before us, may I assume that the leading men in physiology, and the leading men in the two branches of the medical profession, are quite as desirous to promote humanity as eminent men in the other branches of science?—Yes.

280. And that they would be glad that any reproach which any imputation of abuse would cast upon them, should be removed by proper and reasonable measures?—Yes.

281. And that they would be inclined to come forward to support the Crown and Parliament in such measures?—I think that there might be a doubt in their minds whether the changes required would be better accomplished by public opinion or by legislation; in any case, they would be very glad to have any abuse of experiments upon animals, that can be proved, reduced or abolished.

282. Now do you think (indeed you have already said so), that the repetition of experiments is not justifiable?—Certainly it is not.

283. That is to say, that when a scientific fact has been fully established, to repeat a painful experiment for the purpose of illustrating that fact to a new class of students is not justifiable?—Certainly not.

284. And ought not to be permitted?—Certainly it ought not.

285. Ought students under any circumstances to perform these painful operations themselves?—No; and I should be glad to state that there are regulations of the College of Surgeons, and, I think, of other examining bodies, to the effect that the students are not expected to do them. It is appended to the regulations requiring students to attend courses of practical physiology; and it states that the students themselves are not expected to perform experiments on living animals.

286. (*Lord Winmarleigh.*) Are they forbidden to perform them?—I do not think that they could be forbidden by any regulation issuing from a central educational authority; but they are in no sort required to do them, and, so far as I know, they never do them.

287. (*Chairman.*) Would you have any objection to give the Commission those regulations?—Certainly not.*

288. Will you kindly send them to us?—Yes. I do not remember the precise terms of the regulation, but it is to the effect that students are required to attend a course in practical physiology; but then it is added as a note, that students are not required to perform experiments, or painful experiments, on living animals. But I will send you the very words.

289. The object of the regulation being to discourage the practice?—To discourage it in every way.

290. Do you think that it is justifiable to perform painful experiments before a class?—No.

291. Do you think that the number of experiments, even without pain, that is to say, under anæsthetics, should be limited as much as possible?—Yes, they should be limited, I should say, to the illustration of those parts of knowledge which you cannot reasonably expect to communicate by words or drawings or by any other means.

292. Now what sort of experiments do you consider to be really necessary?—As an illustration, I think that every student should see a heart acting; and that can be shown without the infliction of any other pain than the pain, for instance, of decapitation in a large amphibious animal, such as a turtle; or it can be shown, under the influence of anæsthetics and with the help of artificial respiration, upon any warm-blooded animal, so as to produce no pain at all; and at the end of it the animal will be killed and have literally suffered no other distress than that of taking the anæsthetic. I think it is scarcely possible that a student can understand the way in which a heart acts unless he has seen one act.

293. Are there any experiments which do necessarily inflict pain, which you consider to be necessary experiments? Speaking now not of an exhibition to a class, but of experiments for the promotion of science, are there any which do necessarily inflict pain and which you think cannot be dispensed with?—If they are for the promotion of science, and not for the ascertainment of facts already ascertained, then I should answer that there are some.

294. Would you be so good as to illustrate that?—I can of course only illustrate it by cases in which the experiments have been already performed, and with a good result; and I would take, for example, the case of the ligature of arteries, for the cure of aneurisms or for the prevention of bleeding. Now although one might, by observations upon men alone in cases of accident, possibly, without reference to animals, have thought of tying an artery for the cure of aneurism, yet the manner in which it should be done, and all the precautions which have to be taken during the operation, and which have to be observed afterwards, could not have been ascertained by observations upon men alone, but were facilitated and made complete by operations upon animals, in which as far as possible the ligature of the artery was carried out in the same manner as it might be in men.

295. Then in such a case the suffering caused by the operation like that in the human being would be taken away by the use of anæsthetics?—It would be now if further observations are required. I am speaking of experiments upon animals that were made before the discovery of anæsthetics, by Hunter and others after his time; but the whole process of the recovery of an artery after ligature, and the means essential to its recovery, and the exact knowledge of all the process by which the artery is closed, could not have been ascertained without experiments upon animals; because it is as essential to know the whole process of the recovery as it is to know the particular manner in which the operation is to be performed. You might refer to a number of operations that were done for the ligature of arteries (some of which were done by Hunter himself, and some by those who followed him,) which failed, and the patients lives were lost, simply because at that time surgeons had not

---

* Appendix III., § 2.

Sir J. Paget, Bart.

5 July 1875.

ascertained the whole nature of the process for the repair of the injury done by the operation.

296. If such an experiment were performed now the operation would be performed under chloroform, and the pain of the recovery would be all to which the animal would be subjected?—Yes, which pain must be comparatively trivial, I imagine. It is so in man; it is usually an unimportant pain which he suffers in recovering.

297. Then I may conclude that very painful experiments are, in your opinion, very rarely necessary?—Very rarely.

298. That all the experiments which can be performed without pain it is the bounden duty of the surgeon to perform without pain?—Yes.

299. And that wherever there is some pain that must be suffered, the most merciful measures possible ought to be taken?—Yes.

300. With great care and great forethought?—Yes.

301. And that it should be limited to persons of great competence, and not thrown loose for anybody who chooses to perform?—Yes.

302. Are you of opinion that of late years more reliance has been placed than formerly upon experiments?—It is very difficult to say, because all medical inquiry has become of late years very much more active than it was 30 or 50 years ago; and it may be that the present course of inquiry leads to subjects which can scarcely be investigated except by experiments; but on the whole I am disposed to think that experiments have, sometimes, been entered on before all other methods of inquiry have been exhausted; that they have been, so to speak, rather premature than really necessary; for I should hold that an experiment on animals should for the most part not be made till one is quite satisfied that all other means of inquiry have been fairly exhausted, and exhausted in vain.

303. Now as you know our inquiry is not limited to the common term vivisection, but it embraces all experiments upon living animals?—Yes.

304. Some experiments upon living animals illustrate the operation of poisons, do not they?—Yes.
